When XML_STYLESHEET=IMBED(ddname=*ddname*,MEMBER=*member*) is specified, the XML data is imbedded in the specified XSLT stylesheet, resulting in one output file containing both the XSLT stylesheet and the XML data. A processing instruction is added to transform the XML document by itself, so opening just this one XML file with a web browser (or any other program that supports XSLT stylesheets) shows the transformed result. You can use imbedding to guarantee that the recipient of the report has the XSLT stylesheet available. You can omit the ddname= clause; by default the CARLa library is used. The resulting XML data must be saved with extension xml, or served as mimetype application/xml. You can find an example of an XSLT stylesheet to transform the XML data to nicely formatted HTML tables in member C2RXSL01 in the SCKRCARL data set. The stylesheet is also available on the web: http://publib.boulder.ibm.com/infocenter/tivihelp/v2r1/topic/com.ibm.zsecure.doc_1.13/c2rxsl01.xsl. This generic XSLT stylesheet can transform most tabular reports specified in CARLa. Using this XSLT stylesheet allows looking at the data in a web browser, and importing the data into Microsoft Excel 2002 and up.

The stylesheet supplied with IBM Security zSecure can be used for both linking from the XML, and imbedding the XML, for example, with

```
fileoption dd=output fileformat=xml xml_datadict
   xml_stylesheet=uri("http://publib.boulder.ibm.com/infocenter/
                       tivihelp/v2r1/topic/com.ibm.zsecure.doc_1.12/c2rxsl01.xsl")
```

or

```
fileoption dd=output fileformat=xml xml_datadict xml_stylesheet=imbed(m=c2rxsl01)
```

Note that for security reasons, most web browsers do not transform an XML document on one internet domain with an XSLT stylesheet from another domain. You may need to copy the XSLT stylesheet to your own domain, or copy it to the local disk, or use imbedding.

To use the stylesheet supplied with IBM Security zSecure, an XML data dictionary must be included with the XML. See "XML_DATADICT" on page 784. The XSLT stylesheet only handles tabular reports. If a MERGELIST report is created, all columns in all SORTLIST/SUMMARY statements in the MERGELIST must be the same. The title used on the generated HTML page is the default top title or explicit TOPTITLE from the first NEWLIST in the report. Every separate report shows the title and subtitle specified on the NEWLIST (or the first NEWLIST in case of a MERGELIST).

You can also create and use your own XSLT stylesheet. The stylesheet must be in EBCDIC format. The <xsl:stylesheet> and </xsl:stylesheet> elements must be on separate lines and be the only elements on those lines.

XML_STYLESHEET=NO turns off generating the processing instruction.

If XML_STYLESHEET=IMBED is specified, no DTD will be generated. In this case, XML_DTD cannot be specified. See option XML_DTD. By default, no xml-stylesheet processing instruction will be generated.

Examples

The following is an example to create a RACF user report on z/OS UNIX, which links to an XSLT stylesheet. The allocation is done using alloc type=output, but could have also been done using other allocation, JCL for example.

```
alloc type=racf backup active

alloc type=output dd=auditrpt,
   path='/u/reports/user-special-report-dd060717.xml'
```

```
fileoption dd=auditrpt encoding=UTF-8 fileformat=XML xml_datadict,
   xml_stylesheet=uri("http://publib.boulder.ibm.com/infocenter/tivihelp
            v2r1/topic/com.ibm.zsecure.doc_1.12/c2rxsl01.xsl")

newlist type=racf dd=auditrpt name=userrpt
   select class=user segment=base special
   sortlist key(8) pgmrname revoke(1,hb) revoke_inactive(1,hb),
      restricted(1,hb) protected(1,hb)
```

This example creates an SMF report. It uses an imbedded stylesheet.

```
alloc type=smf active
alloc type=ckfreeze dsn=SYSAPPL.DAILY.CKFREEZE

alloc type=output dd=auditrpt,
   path='/u/reports/smf-special-report-dd060717.xml'
fileoption dd=auditrpt encoding=UTF-8 fileformat=XML xml_datadict,
   xml_stylesheet=imbed(m=c2rxsl01)

newlist type=smf dd=auditrpt name=smfrpt
   select userid:special
   sortlist datetime recorddesc
```

IMBED / INCLUDE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

Use the IMBED or INCLUDE command for running commands from a different source than the source specified by the program or command parameters, and the SYSIN file. The INCLUDE commands can be nested. That is, the input commands can contain another INCLUDE command. The main use of this command is to include sample or user-defined members; this can be used to share queries or output displays. Using the INCLUDE command to include a standard installation-defined member is a simple customization option.

The commands are read immediately after the INCLUDE statement ends. After the secondary input source has been exhausted, processing of the original input source is resumed at the token that terminated the INCLUDE statement. The input listing clearly shows the origin of the input commands.

The parameters are:

ddname= *file*
DD=*file* **FILE=***file*
F=*file*
To imbed the contents of a sequential file or (in combination with the MEMBER parameter) to denote the file containing the member to be imbedded. If MEMBER is specified as well, a partitioned data set (concatenation) must be allocated to the file. This parameter is mutually exclusive with the PATH and FILEDESC parameters.

ESM= *list*
This parameter can contain one name or a list of names of External Security Manager systems. The program only imbeds the file if one of the ESMs mentioned is present on the system running the CARLa.

FILEDESC= *number*
To imbed the contents of an already opened input file. When running the program in a UNIX environment, file descriptor 0 is already processed instead

of SYSIN. It is most useful for passing commands between processes through a pipe. This parameter is mutually exclusive with DD, MEM, PATH.

LICENSE= *list*
This parameter can be used to perform the imbed only if any of the products in the list is currently installed and not disabled through IFAPRDxx. Typically, this parameter is used to prevent syntax errors for non-full-function products.

MEMBER= *name*
MEM=*name*
To imbed the contents of a PDS member. If the ddname parameter is also present, the PDS allocated to that file is used. If the ddname parameter is omitted, the DDname CKRCARLA is assumed. On VM/CMS, the filename allocated to the indicated or defaulted FILEDEF is checked. If it is ISPNULL, the filename is replaced by the indicated MEMBER using the filetype and filemode from the FILEDEF. This behavior is consistent with ISPF use of FILEDEFs for ISPF libraries of the type 'set of CMS files'. This parameter is mutually exclusive with the PATH and FILEDESC parameters.

MARGINS=(*nn,ll***)**
MARGINS(*nn,ll***)**
Set the margins for the included file or member. The default is (1,72) for RECFM=F(B),LRECL=80 input files, and the whole line otherwise.

N
NOLIST
Do not give a listing of the member to be included. This setting propagates down to lower level includes.

NODUP
This parameter can be used to prevent the program from imbedding the same member or sequential file twice (Which can lead to syntax errors). It is not supported for the PATH or FILEDESC method of specifying imbed files.

PATH=' *path/file***'**
To imbed the contents of a UNIX file. The quotations are required. The path and filename are case sensitive. This parameter is mutually exclusive with DD, MEM, FILEDESC

ISPFVAR= *name*
VAR=*name*
V=*name*
To imbed the contents of an ISPF variable. The variable must be present in any of the ISPF variable pools (implicit, shared, profile). If the variable cannot be found, an error message is issued.

LIMIT

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

The limit command can be used to set limits on execution or number of error messages. LIMIT may be abbreviated to LIM. This command is not supported in restricted mode.

FOCUS= focus | (focus, focus, ...)
This reduces the functionality of the CKRCARLA program to the product code indicated. This is used by zSecure Alert to make sure its workload is attributed to the right product.

Table 295 lists the available product codes with the corresponding product for each code.

Table 295. Supported product codes

ALERTRACF	zSecure Alert for RACF
AUDITRACF	zSecure Audit for RACF
TCIMRACF	Tivoli Compliance Insight Manager Enabler for z/OS RACF
TCIMCICS	Tivoli Compliance Insight Manager Enabler for CICS
TCIMDB2	Tivoli Compliance Insight Manager Enable for DB2
ADMINRACF	zSecure Admin
zsecure_visual_s	zSecure Visual

The default focus is all of the table above except the product codes starting with ALERT. These have to be specified explicitly to be used.

IN= *nn*
I=*nn*
For RACF complexes, this parameter causes input from the RACF database to stop after the specified number of profiles and segments has been read from the RACF database. This parameter is meant for testing purposes to improve response time, e.g. when testing a new report layout. This parameter does not limit the number of SMF records read, use the LIMIT SMFIN=*nn* parameter.

OUT= *nn*
O=*nnn*
For RACF complexes, this parameter causes input from the RACF database to stop after the specified number of profiles and segments has been selected from the RACF database by the outer level SELECT/EXCLUDE parameters. This parameter was originally meant for testing purposes to improve response time, for example, when testing a new report layout. The difference with the NEWLIST OUTLIM= parameter is that LIMIT OUT= has repercussions for all NEWLIST, verify, and report commands that use security database input, while NEWLIST OUTLIM= is limited in effect to the specific NEWLIST. In general, we recommend using NEWLIST OUTLIM= instead of LIMIT OUT= unless you are stress-testing the product's capability to cope with missing security definitions.

ABEND
To cause an abend on certain severity 20 error conditions. Only use this at the request of IBM software support.

MSG= *nn*
M=*nnn*
To set a limit on the number of error messages for a specific volume serial or catalog. The default is 50. If there are more messages than this limit for a specific volume serial or catalog, the surplus is suppressed.

GENERIC
To limit the output of the commands REPORT and (RE)MOVE with the options NONREDUNDANT and REDUNDANT to generic profiles only.

DISCRETE
To limit the output of the commands REPORT and (RE)MOVE with the options NONREDUNDANT and REDUNDANT to discrete profiles only.

ID= *id*
To limit messages and reports to lines concerning a specific user or group. This option merely reduces output, not the processing time. Often SELECT QUAL= is a better choice.

SMFIN= *nn*
To stop reading SMF after the specified number of records has been read.

The LIMIT command is used outside the context of a NEWLIST command. The SMFIN, LIMIT command is used with the NEWLIST TYPE=SMF to limit the amount of SMF records read. For a usage example, see "Example: limit smfin" on page 790.

SMFDD= *number*
Specifies the maximum number of DD names that are used for SMF. The default value of 100 supports previous releases; the maximum number is 1036. The SMFDD=*number* limit is typically used in conjunction with ALLOC DSNPREF=*prefix*, which processes multiple data sets by using one command. If you specify a large maximum number of DD names for SMFDD, be sure to specify a large REGION size in the job step. An error message is generated if the REGION value is too small.

INDEXBIAS=[2 | *nn*]
This parameter can be used to influence the heuristic algorithm that decides whether to switch from indexed I/O to multi-track sequential I/O while reading a data set of a RACF database.

With an index bias of 1 the switch to sequential I/O is done if the number of queued RBA requests exceeds the number of I/O operations necessary to read the whole RACF data set. This is called the index cutoff point.

With bias 2 this cutoff point is the double number of requests. Generally this is expected to increase CPU and I/O for queries that will switch anyway, but will decrease CPU for queries that did not really need to be switched performance-wise. With bias 3 the cutoff point is three times the number of requests, and so on.

The default is 2. Sequential I/O can be favored by setting LIMIT INDEXBIAS=1 in the preamble. Indexed I/O can be further favored by specifying LIMIT INDEXBIAS=3 or more. Sequential I/O can be enforced by SUPPRESS INDEX (see "SUPPRESS INDEX" on page 936). Indexed I/O can be enforced whenever possible with SUPPRESS INDEXCUTOFF (see "SUPPRESS INDEXCUTOFF" on page 936).

The specification has no effect when BDAMQSAM has been specified.

Example - limit discrete

To remove redundant discrete profiles but not redundant generic profiles, the scope of the REMOVE REDUNDANT command can be restricted to discretes by the following command sequence.

```
remove redundant
limit discrete
```

Example - limit msg

You may not see all detail error messages resulting from a VERIFY command on the first run, because of the default message limit of 50 messages per volume. If this is the case, you receive the message:

```
CKR091I volser message limit exceeded- nn messages suppressed
```

To see all detail messages, the message limit should be increased. This can be accomplished by setting it to a sufficiently high value (at least the current limit plus the amount of messages suppressed according to the message). For instance:

```
limit msg=1000
```

Example: limit smfin

```
/* Read at most 10,000 SMF records */
limit smfin=10000
```

When the input limit has been reached, Security zSecure terminates reading of the SMF input files. The remaining records in the input files are not read and cannot be selected, listed or unloaded.

This option is mainly of use in case of response time or memory use problems. To restrict the number of records displayed for any single report, use the OUTLIM parameter of the NEWLIST command. Security zSecure terminates reading the SMF input files if all output limits have been reached.

LANGUAGE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

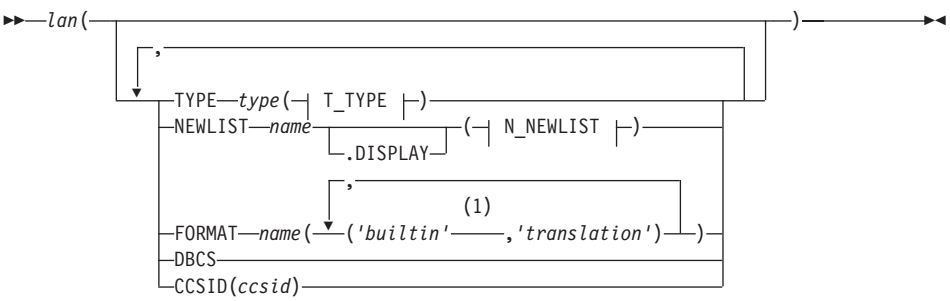
The LANGUAGE command provides the specification for translating CARLa NEWLIST reporting elements and activates translation for certain named NEWLIST types (reports). The LANGUAGE command cannot be abbreviated.

When generating reports, all LANGUAGE commands must precede the use of any NEWLIST statement or field names in the command input stream. Multiple LANGUAGE commands for the same language (lan) can be coded in a single report generation. However, all commands must refer to the same language. For example, you cannot submit commands for LANGUAGE JPN and LANGUAGE KOR in the same report.

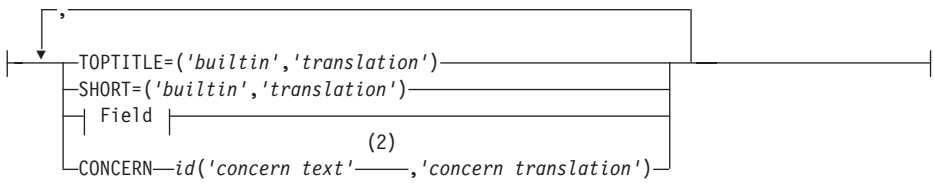
If duplicate parameters are located on subsequent LANGUAGE commands, the last value read from the input takes precedence.

The format of the LANGUAGE command is shown in the following syntax diagram:

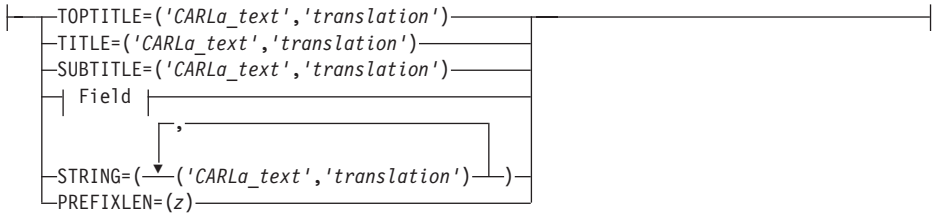
Language



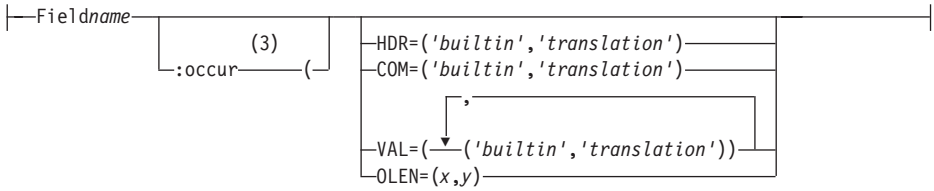
T_TYPE:



N_NEWLIST:



Field:



Notes:

1 The quotations shown around the strings 'builtin' and 'translation' are required. You can use three types of quotation marks: the single quote ('), a double quote ("), and a backquote (`).

2 The strings 'concern text' and 'concern translation' can contain one or more `&variables`,

3 Occurrence number `:occur` is only valid on `FIELD` command under NEWLIST, not under TYPE.

Field descriptions

lan

A three-character code that identifies the translation language.

CCSID (*ccsid***)**

Enter the CCSID of the language being processed (optional). This value is not currently used, but can be provided in case it is needed later.

DBCS

Indicates if the translation language is a DBCS language. This setting controls the following processing behavior:

- Default NEWLIST headers are printed in *asis* format and not interspersed with blanks to make them wider.
- Selecting and excluding using the string scan operator =: uses a DBCS-enabled scan function. Non-DBCS search arguments are not found in DBCS sections of the string, while DBCS search arguments are found only in DBCS sections.

Note: The search results are unpredictable if the string has any invalid DBCS section, binary data that has a stray X'0E') for example.

FORMAT name(('*builtin***','***translation***') [,('***builtin***','***translation***')]...)**

The FORMAT strings are to be translated from the string variable *builtin* to the string variable *translation*. The *builtin* ,*translation* pair can be repeated as many times as required. For example, strings like YES and NO might be translated in a single statement.

NEWLIST name | name.display

This phrase indicates that parameters that follow in parentheses are to be used as the translation instruction for a `NEWLIST NAME=name` statement. Besides giving the translation for this language, this clause also activates actual translation for the indicated NEWLIST. For a DISPLAY statement the name used in `NEWLIST NAME=name` must be suffixed with `.display` in the LANGUAGE NEWLIST clause to disambiguate a display format NEWLIST from the print format NEWLIST with the same name.

FIELD name [:occur]
The field name and optional occurrence number of the NEWLIST field that the language translation applies to.

COM=('*CARLa_text***','***translation***')**
The PREFIX header (field label) of *CARLa_text* for the `FIELD name` is to be translated to the string translation.

HDR=('*CARLa_text***','***translation***')**
The Column Header string of *CARLa_text* for the `FIELD name` is to be translated to the string translation.

OLEN=(*x,y***)**
The output length (column width) of the FIELD name has to be changed from the `actuallength` x, to the `translationlength` y.

VAL=(('*CARLa_text***','***translation***') [,('***CARLa_text***','***translation***')]...)**
The value strings associated with the field name are to be translated from

the string builtin to the string translation. The (*'CARLa_text '*,*'translation'*) pair can be repeated as many times as required.

PREFIXLEN=(x)
Overrides the default PREFIX header (field label) length of 29 for translations where the length is longer than 29. Valid values are 29 to 70 inclusive.

STRING=('*CARLa_text***','***translation***')**
The String value of *CARLa_text* for the FIELD name is to be translated to the string translation.

SUBTITLE=('*CARLa_text***','***translation***')**
Indicates the SUBTITLE string of *CARLa_text* in the NEWLIST name is to be translated to the string translation.

TITLE=('*CARLa_text***','***translation***')**
Indicates the TITLE string of *CARLa_text* in the NEWLIST name is to be translated to the string translation.

TOPTITLE=('*CARLa_text***','***translation***')**
Indicates the TOPTITLE string of *CARLa_text* in the NEWLIST name is to be translated to the string translation.

TYPE *type*

The TYPE=*type* command indicates that the parameters that follow are the default translation for a `NEWLIST TYPE=TYPE`. By itself, this clause does not activate the actual translation. The translation is activated by the `NEWLIST name` clause of the LANGUAGE statement or by the `LANGUAGE=` parameter on the NEWLIST statement.

The TYPE command supports the following parameters.

CONCERN id('*builtin***','***translation***')**
This parameter indicates that the default CONCERN with ID *id* and string *builtin* is to be translated to the string translation.

Variables are presented by ampersand (&) and end with a period (.), for example `&1.`. The translated string can use variables in a different order and put them in a different position in the string.

FIELD *name*
The field name associated with the NEWLIST type that the language translation applies to.

Note: The `FIELD` *name* clause for the TYPE NEWLIST does not support the `:occur` option for specifying the NEWLIST field occurrence number. This option is supported on the `FIELD` *name* clause for the LANGUAGE statement.

COM=('*builtin***','***translation***')**
The PREFIX header (field label) of *builtin* for the `FIELD name` is to be translated to the string translation.

HDR=('*builtin***','***translation***')**
The Column Header string of *builtin* for the `FIELD name` is to be translated to the string translation.

OLEN=(*x,y***)**
The output length (column width) of the FIELD name has to be changed from the *actual length x*, to the *translation length y*.

VAL=(('*builtin*','*translation*'**) [,(**'*CARLa_text*','*translation*'**)]...)**
The value strings associated with the field name are to be translated from the string builtin to the string translation. The ('*builtin*','*translation*') pair can be repeated as many times as required.

SHORT=('*builtin*','*translation*'**)**
This field is not implemented.

TOPTITLE=('*builtin*','*translation*'**)**
Indicates the default TOPTITLE string of *builtin* for the NEWLIST type is to be translated to the string translation.

LIST family of commands

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

The **LIST** commands request formatted output of the profile records selected using the **SELECT** and **EXCLUDE** commands. Output is sent to the destination specified using the **PRINT** or **NEWLIST** command. The destination can be a SYSPRINT file or other output destination such as an ISPF display. These commands have a similar syntax. For each selected profile, the fields specified as parameters in the LIST command are list. For information about different output files or simultaneous multiple reports, see the NEWLIST command. Table 296 shows the commands included in the LIST family.

Table 296. LIST family of commands

Command	Description	Sorted	Headers
LIST	Output to file	No	Page headers
SORTLIST	Output to file	Yes	Page and Column headers, if output to SYSPRINT/CKREPORT
DISPLAY	ISPF table	Yes	ISPF
SUMMARY	Summary report	Yes	Page and Column headers, if output to SYSPRINT/CKREPORT
DSUMMARY	ISPF summary table	Yes	ISPF

Note that the LIST command behaves differently from the other commands from this family, in that it generates output for each record at the moment that record is read. This has the advantages of a reduced need for storage and a slightly higher speed. It has the significant disadvantage that nothing is kept in storage, which implies that post-processing is impossible. Several NEWLIST and OPTION parameters suffer from this restriction, which is not always obvious. For this reason, use the LIST command only if strictly necessary.

Note that the DISPLAY command behaves like the SORTLIST command when not in ISPF. When the SUMMARY command is combined with a DISPLAY command, it behaves like DSUMMARY.

If you want to use the (SORT)LIST command for TSO command generation, you may want to suppress page headers. Use the PRINT NOPAGE or NEWLIST NOPAGE command to do so.

The LIST command is not supported in restricted mode for NEWLIST TYPE=RACF (the default list type), but the SORTLIST and DISPLAY commands are supported. Some fields cannot be used on the LIST command, notably the ACL field.

Details on the LIST family of commands describe report and display options, output formatting, and other processing that applies to these commands. For additional information about LIST family commands other than the LIST command, see the following sections:

- "DSUMMARY" on page 778
- "SORTLIST" on page 918
- "SUMMARY" on page 918

Controlling report and display output for LIST family commands

CARLa provides a number of parameters to control report display and output using the LIST family of commands. These parameters include output modifiers and format names. The following sections describe how zSecure report and display processing works and explains how to use the output modifiers and format names to control the behavior and appearance of display and report output.

Note that not all modifiers and formats are available for all commands and that different modifiers and formats are available based on field type (repeat group, non-repeat group, flag, and date fields, for example). These sections also include examples of using the output and format modifiers. Additional examples are provided in "Using the LIST command" on page 832

- "Repeat groups and repeated fields: Understanding the output list processing" on page 796
- "Parameter syntax: Specifying parameters for LIST/SORTLIST/DISPLAY commands" on page 796
- "Indirect references: Using lookup" on page 796
- "Modifying output length" on page 797
- "Modifying output format" on page 798
- "General output modifiers: Controlling field-related output" on page 798
- "Display modifiers: Changing field output display in ISPF" on page 802
- "Non-repeated field output modifiers: Changing how information is displayed" on page 803
- "Repeated field output modifiers: Changing display of Repeated fields" on page 804
- "Summary statistic modifiers: Changing the output display for SUMMARY operations" on page 809
- "Modifying the column header" on page 809
- "Changing the sort order" on page 809
- "Format names for input and output" on page 810
- "Specifying syntax for RACF command input" on page 810
- "Flag formats: Using available formats for flag field input and ouput" on page 826
- "Date output formats: Formatting date field output for different locales and standards" on page 828

Repeat groups and repeated fields: Understanding the output list processing

If the field is part of a repeat group, the listing contains as many lines as necessary to list all member values in a column. If two fields are displayed that are part of the same repeat group such as the ACL fields `USERACS` and `USERID`, the corresponding repeat group values appear on the same line unless one of the columns contains the SORT format modifier.

If the output listing contains one or more repeat group fields (profile key, for example), the first line contains all non-repeat group fields and the first value of each repeat group field. All fields that are not part of a repeat group are blank in subsequent lines unless the RETAIN parameter was specified on theOPTION or NEWLIST command.

Parameter syntax: Specifying parameters for LIST/SORTLIST/ DISPLAY commands

The parameters to the LIST/SORTLIST/DISPLAY commands must either be:

- *strings* enclosed in single, double, or left quotations, with a maximum length of 512 characters.
- For `NEWLIST TYPE=RACF`, field names as defined by the templates ("TEMPLATE - Template field properties" on page 284) or built-in *pseudo-fields*. For other NEWLIST types, pre-defined *field names* as defined in this manual. All fields available are described in SELECT/LIST fields.
- Boolean, summary, or subselect *variables* defined with the DEFINE command (see "DEFINE" on page 750).
- *indirect references* (also called *lookup*) as described in "Indirect reference or lookup" on page 764.
- the *concatenation operator* `'|'` (a vertical bar).
- the *newline operator* `'/'` (a slash).
- the *soft newline operator* `/n` (valid on the following commands: `SORT`, `SORTLIST` and `SUMMARY` only)

In addition, the `DSUMMARY` and `SUMMARY` commands support the following syntax:

- the *summary level operator* `*` (an asterisk).
- The parameters can be separated by blanks or commas. If the statement needs to be continued on the next line, the last parameter on the line must be followed by a comma.
- The parameters containing field names (or their aliases) can be immediately followed by a list of *output modifiers* enclosed in parentheses.

  The output modifiers are: length, format, repeat group format modifiers, non-repeat group modifiers, general format modifiers, and an overriding column header. An output field can be specified using the following syntax. For additional information, see "Modifying output format" on page 798.

  ```
  fieldname
  fieldname:reference
  fieldname(length,format,modifier,'header',...)
  ```

  Note: The concatenation, newline, and summary level operators must be separated from parameters by either blanks or commas.

Indirect references: Using lookup

Indirect references (also called *lookup*) are fully described in "Indirect reference or lookup" on page 764.

Note that for a NEWLIST TYPE=RACF, the LIST command does not support indirect references.

If the base field name is not present separately in the output command, it is automatically inserted before the look-up field, and it receives the NONDISPLAY output modifier. Note that this can influence the sort order. If you want to sort on the lookup field, make that the base field is present in the output command *behind* the look-up field. You may use the NONDISPLAY output modifier if you do not want the base field to be present in the output.

For the use of indirect references in the summary, see "Indirect references in a summary" on page 926.

Modifying output length

Optionally, a field name may be followed by a *length* in parentheses. This number indicates the number of output positions into which the field should be formatted. Most fields have default lengths predefined that are sufficient for standard usage. If the NEWLIST TYPE=RACF field is defined as a variable length field in the template *and* no default length is set by Security zSecure (this is listed on the SHOW TEMPLATES output) *and* no explicit length is provided on the LIST command, the actual length is used for each profile. This results in disturbance of the column layout, because all subsequent fields start at a varying position.

The overriding output length 0 has a special meaning, dependent on the command issued. For the DISPLAY command it can only be used on the last field on a line. If the output field is not modifiable, it will then use all remaining space on the line on the screen. A modifiable field will allocate the maximum input length supported for the field or its output format. This may require many scroll-right operations to reach the end of the field for, e.g., a maximum input length of 1023. If WRAP is also specified, the field will wrap at end of screen - but only if the current contents are longer than fits on the screen (no right scrolling is required in this case). If the current contents fit on the screen in the first line, but the field maximum length is longer than fits on the screen, WRAP will cause the field to be extended just to the end of the screen but not generate continuation lines - this means that the maximum input length cannot necessarily be entered when WRAP has been specified. For the (SORT)LIST command it means that trailing blanks must be trimmed (stripped) from the output. It generally results in a ragged column layout, but can be used to generate your own TSO commands. The following example will put quotations around a profile key.

```
sortlist "'" | key(0) | "'"
```

With a (D)SUMMARY command, an overriding output length has a special meaning. The summary will be done after recalculating the value off the field to match the specified length. For example, in the following code data is summarized on the first four characters of the user ID. An overriding length of zero on a (D)SUMMARY command thus generates no useful output.

```
select class=user segment=base
sortlist key owner name
summary key(4)
```

Instead of defining length values using numerals, you can use the SYMBOLIC statement (`SYMBOLIC NUM name=value`) to define a symbolic name for a numeric value. The symbolic name can be used on its own or associated with a numeric default value that is used if the symbolic has not been defined. The default value is specified as `name|value` as shown in the following examples: "SYMBOLIC" on page 940.

```
SELECT NUMBERFIELD>maxlength
SELECT NUMBERFIELD>maxlength|20
```

In the CARLa command input, the symbolic name must be defined before its first use. If you use the conditional specification, the value is the default value that is used only if the SYMBOLIC statement has not been defined. For more information and usage restrictions, see "SYMBOLIC" on page 940.

Modifying output format

Instead of the length, or in addition to it, a *format* can be defined. An output format changes the way a field is displayed. Generally this is unnecessary, but it may for instance be used to display dates in US format, to print a suspect value in hexadecimal, or to generate TSO commands. The output formats that can be specified are described under "Specifying syntax for RACF command input" on page 810. This section includes a list of special output formats starting with a **$** that are used to generate TSO commands.

General output modifiers: Controlling field-related output

General output modifiers are available to change the way a field appears or behaves in reports and displays and to control aspects of the report output such as changing the page title to include the field value. General output modifiers use the same syntax as output formats, in parentheses following a field name (`fieldname(INDENT(indent_fieldname)`). A field can have both general output modifiers and output formats specified together. and can be included in addition to output formats. They apply to both repeated and non-repeated fields. The following general output modifiers are provided:

ALLOWRESTRICT
: Allow a restricted field in a query in restricted mode. Messages CKR0217 and CKR0384 are still issued, but with severity 4 (warning) instead of 12 (syntax error). The resulting report will be generated with an empty column for the restricted field. If you want to allow this for all fields in the query, use the ALLOWRESTRICT modifier on the NEWLIST command. If you want to suppress an entire query in restricted mode rather, use the UNRESTRICTED modifier on the NEWLIST command. See "OPTION" on page 856.

BOTH
FIRST
: This modifier has effect on ISPF displays only. It specifies that the field should be shown on both the overview and the detail panel. For a repeated field, the first value will be shown on the overview panel, unless the repeat group modifier MORE is also specified. This modifier is mutually exclusive with DETAIL and NODETAIL. It is subordinate to NONDISPL.

CONDPAGE(nnn)
CP(nnn)
: The CONDPAGE modifier can be used to force the start of a new page in a report that is written to file if there are not enough lines left on the current page to print a section. The number specified between parentheses is the minimum number of lines needed on the current page. If there are less lines than specified left, a new page is started. Any number between 1 and 255 can be specified and the modifier can only be used on the first field or string on a line.

DESCENDING
BW
: Reverses the sort order for this column. Note that this is used to sort *records*, not repeated field instances. When used on a repeated field, the record sort

order for this column is descending for the first repeated field instance. Use the SORT(DESCENDING) output modifier to change the sort order within a repeated field.

DETAIL
D

This modifier has effect on ISPF displays only. It specifies that the field should be shown on the detail panel, and not on the overview panel. This modifier is mutually exclusive with BOTH and NODETAIL. It is subordinate to NONDISPL. Its effect can also be specified as default for all fields with the NEWLIST option DETAIL. Note that a DISPLAY command must show output on the overview panel.

INDENT

Displays the field with an indentation determined by the parameter to INDENT, which must be a numeric (one to four byte integer) field to the right of the indented field on the same command (and level, for a summary).

The syntax of the INDENT output modifier is:

```
fieldname(INDENT(indent_fieldname))

fieldname          any field name
indent_fieldname   any field name that has a numeric value
```

This modifier is useful in a group-tree display where `KEY(40,INDENT(DEPTH))` displays each group name in a 40 character wide column. Each group name is prefixed by blanks to indicate the depth within the group tree. If a repeated field is indented by a non-repeated field or a repeated field with the FIRSTONLY modifier, each entry of the repeated field is indented by the non-repeated field value. If a repeated field is indented by another repeated field, the first entry of the former is indented by the first of the latter, the second by the second, and so on. A missing value results in no indentation. The `INDENT` setting is a print phase modifier, which means that the prefixed blanks are not used for sorting or summarizing. Do not combine indenting a repeated field by another repeated field with a `SORT`, `WRAP` or `WORDWRAP` modifier or with the `DUMP` output format on either field. This type of combination produces confusing report formatting.

KEY

On an ISPF display, the field is a *key field*. When scrolling left/right, the key fields always remain on the display. That is, only the non-key fields are scrolled left and right. Key fields must be adjacent. You cannot have a key field followed by a non-key field followed by a key field.

NOMODIFY

Set the field to non-modifiable. This is only of use in ISPF displays. This parameter overrides the NEWLIST setting.

NODETAIL

This modifier has effect on ISPF displays only. It specifies that the field should be shown on the overview panel, and not on the detail panel. For a repeated field, the first value will be shown on the overview panel, unless the repeat group modifier MORE is also specified. This modifier is mutually exclusive with BOTH and DETAIL. It is subordinate to NONDISPL.

NONDISPL
NONDISPLAY

ND
Do not display / list the value for this field. This is useful for changing the sort order without having to display the sort key (in that specific position or anywhere), or to hide a summary key.

NOPREFIX
Locally override a NEWLIST HEADER=PREFIX and in this way suppress the 30 character field comment prefix.

NOSORTLIST
This modifier can be used to exclude a column from the record sort key. The record sort key consists of the fields listed in the output specification (for example SORTLIST, SUMMARY). As an alternative to using the NOSORTLIST output modifier, you can also explicitly specify the sort key through the list of fields by using the NONDISPLAY output modifier, as shown in the following examples:

```
Display key(8,NOSORTLIST) pgmrname(NOSORTLIST) owner

Display owner(NONDISPLAY) key(8) pgmrname owner
```

Using "field(nosortlist)" usually leads to shorter and simpler CARLa statements. Using "field(nondisplay)" has the benefit of requiring less CPU time than "field(nosortlist)" to create similar output.

NOTEMPTY
NE
The NOTEMPTY modifier can be used to suppress the line it is issued on when all fields on it are empty. The modifier can only be used on the first field or string on a line and works only for a report that is written to file, not for an ISPF display.

PAGE
This modifier causes a page eject if the value of the field changes. It does not effect the output position of the field, add TOPTITLE if the field must be displayed as a running variable in the header. More than one field can have the page modifier but they must be concentrated at the beginning of the sortlist statement. The only columns supported on the statement before a field with a PAGE modifier are string literals and newlines. The PAGE modifier cannot work on a LIST statement.

PREFIX
P This modifier specifies that the field value should be prefixed with a descriptive text (a *prefix header*) of 29 characters followed by one blank as a separator. The *prefix header* is generally different from the *column header*, because columns are usually narrow. PREFIX can be specified for all fields at the same time by using the parameter HEADER=PREFIX on an OPTION or NEWLIST statement.

TITLE
T This modifier causes the field to be printed behind the default or explicitly specified title. It is not printed on the regular output line, TOPTITLE and TITLE fields can be freely mixed (have an arbitrary order), but they must come before any fields on the statement that do not have any of the modifiers TITLE, TOPTITLE, or NONDISPL. TOPTITLE and TITLE are mutually exclusive. The TITLE modifier cannot work on a LIST statement. If a repeated field has this modifier, then only the first value is displayed. Title fields start immediately behind any specified NEWLIST TITLE='string' without intervening blanks.

TOPTITLE
TT

This modifier causes the field to be printed behind the default or explicitly specified toptitle. It is not printed on the regular output line. TOPTITLE and TITLE fields can be freely mixed (have an arbitrary order), but they must come before any fields on the statement that do not have any of the modifiers TITLE, TOPTITLE, or NONDISPL. TOPTITLE and TITLE are mutually exclusive. The TOPTITLE modifier cannot work on a LIST statement. If a repeated field has this modifier, then only the first value is displayed. Title fields start immediately behind any specified NEWLIST TOPTITLE='string' without intervening blanks. Specifying any TOPTITLE modifier in the NEWLIST suppresses the automatic display of variables like time stamps and BUNDLEBY variables on the top title, these can be displayed by adding the STAMP field and the bundle variable to the SORTLIST with a TOPTILE modifier.

TRUNCATE
TRUNC

This modifier causes error and warning messages CKR0397 and CKR0218 to be suppressed if the field exceeds the line length or starts beyond end of line.

VARLEN

Force the field to be treated as variable length. This is useful for fields that are automatically treated as fixed length, but then cause message CKR1968 to be issued.

The CKR1968 usually signals an error condition in the database, where the templates indicate the field is fixed length, but there are values in the database that are out of spec. You can look for the erroneous values with the following query:

```
define fieldname(VARLEN) as fieldname
newlist type=racf
display class key segment fieldname(dump)
sum fieldname(fldlen,'Len')
```

The *fieldname* indicated in the CKR1968 message should be substituted. In the resulting summary, look for entries with a length different from 0 and the *expected* length indicated in the message.

If it turns out some field values in the live database are indeed incorrect, you can write a CARLa query to select the offending records and generate corrective RACF or CKGRACF commands for them.

If you want to permanently circumvent (rather than fix) the problem, you can put the DEFINE statement in your PREAMBLE, or in CARLa member C2RXDEFU (which is automatically included in the interface and several sample batch jobs).

UNIVERSAL

This modifier requests to show (access for, the number of) all connects to groups with the UNIVERSAL attribute. It can be used with the ACL, CONNECTS and CONNECT_COUNT fields.

A group without the UNIVERSAL attribute can have at most 5957 connected users, due to a size limit on the list of connected users in the group profile. The UNIVERSAL attribute removes this restriction, as the group profile for a universal group does not list users connected with just USE authority (and no connect attributes like group-special) in the ACLCNT repeat group.

These relatively uninteresting connects are only shown in the ACL, CONNECTS and CONNECT_COUNT pseudo-fields, when the UNIVERSAL modifier has been specified. Note that this may increase the response time of your query, because all user profiles in the database must be examined for a possible connect to the universal group (indexed I/O is disabled).

For the ACL field, this modifier also controls whether access due to system operations may be shown (depending on the other ACL modifiers used), another function that requires all USER profiles to be examined.

WORDWRAP
WW

The WORDWRAP modifier is like the WRAP modifier, except that it splits the line at a word boundary (`=blank`) instead of splitting words across lines. However, if a word is longer than the column is wide, then it forces a split across lines. With this setting, processing does not suppress blanks at that occur at the beginning of a new line.

When a field in a `DISPLAY` statement is specified with the `WORDWRAP` modifier, the field is shown in the Detail ISPF display panel but not in the Overview display panel.

WRAP
W

The `WRAP` modifier without the `HORIZONTAL` setting wraps a field value in the column if it is too wide for the column. This format effectively creates a repeat group display for each value of the field where each subsequent line in the column continues the text of the previous line. If an output length of *0* is specified or implied, the rest of the line is used as the width of the column to wrap in. For output format `HEX*`, an odd column width is supported. The `(WRAP,HEX,0)` specification automatically rounds down to a byte boundary (even width), except for width 1.

`WRAP` is not supported in combination with the following output formats: `HDR$BLANK`, `BLANK$HDR`, `STR$BLANK`, `BLANK$STR`, and `DATE$STR`. If the `HORIZONTAL` modifier is specified for the same field, `WRAP` acts as a secondary modifier to `HORIZONTAL`, see "Repeated field output modifiers: Changing display of Repeated fields" on page 804.

When a field in a `DISPLAY` statement is specified with the `WRAP` modifier, the field is shown in the Detail ISPF display panel but not in the Overview display panel.

Display modifiers: Changing field output display in ISPF

To change the color and intensity of a field on an ISPF display *display output modifiers* are available. The display output modifiers can be specified like and in addition to the output formats, in parentheses following a field name. They apply to both repeated and non-repeated fields. The colors mentioned are default values and can be changed by the ISPF settings. The following display output modifiers are provided:

BOLD
B The field is displayed in bold (highlighted). It will be shown highlighted on a monochrome terminal and blue on a color terminal.

CH

The field is a column header. It will be shown highlighted on a monochrome terminal and blue on a color terminal.

CT
The field is caution text. It will be shown highlighted on a monochrome terminal and yellow on a color terminal.

DEFAULT
L
LID
The field is a list detail field. It will be shown normal on a monochrome terminal and green on a color terminal.

ET
The field is enhanced text. It will be shown highlighted on a monochrome terminal and turquoise on a color terminal.

FP
The field is a field prompt. It will be shown normal on a monochrome terminal and green on a color terminal.

LI
The field is a list key. It will be shown highlighted on a monochrome terminal and white on a color terminal.

NT
The field is normal text. It will be shown normal on a monochrome terminal and green on a color terminal.

PAS
The field is a point-and-shoot field. It will be shown highlighted on a monochrome terminal and turquoise on a color terminal. It functions as a push button in the GUI. This modifier is only valid on fields that have the KEY modifier as well.

SI
The field is scroll information. It will be shown highlighted on a monochrome terminal and white on a color terminal.

WASL
The field is a window area separator line. It will be shown normal on a monochrome terminal and blue on a color terminal.

WT
The field is warning text. It will be shown highlighted on a monochrome terminal and red on a color terminal.

Non-repeated field output modifiers: Changing how information is displayed

For non-repeated fields, specific *non-repeated field output modifiers* can be specified to change the way the information is displayed. This is in addition to the output format that can be specified. The non-repeated field modifiers are:

EXPLODE
Turn a condensed non-repeated field into an expanded repeated field. This output modifier can only be used with the FLAG, FLAG2NICE, KEYUSAGE_RACF, KEYUSAGE_X509, LOGDAYS, RESFLG, YESNO, $YESNO, and $NO formats and the zSecure Audit for ACF2 DESCRIPTOR, REASON, and RACFAUTH fields. The EXPLODE output modifier is also used with the ACL repeat group field, see "Repeated field output modifiers: Changing display of Repeated fields" on page 804.

NORETAIN
Locally override a NEWLIST RETAIN to not repeat the value of this non-repeated field for each line.

RETAIN
Repeat a non-repeated field for each line that is needed to list the contents of all repeated fields on the line. This is for instance useful to generate a TSO command for each occurrence in a repeated field. This can also be specified for all fields at the same time by using the NEWLIST parameter RETAIN.

Repeated field output modifiers: Changing display of Repeated fields

For repeated fields, *repeated field output modifiers* can be specified to change the way in which the information is displayed. This is in addition to the output format that can be specified. The repeated field modifiers are:

EFFECTIVE
Reduce the repeated field such that only relevant entries, showing actual access remain; in case access is only granted implicitly, add an explicit entry.

Currently, EFFECTIVE is only valid on the ACL combination field. Applying it results in an access list display showing all user IDs that have access and the actual access they have through any access list entry, or if they have access due to an operations attribute the group in which they have group operations, or `- oper -` for a system-wide operations attribute.

Whether administrative access is also taken into account depends on the SCOPE modifier (see there). System-wide operations and access of users with default connections to a universal group will only be taken into account if the UNIVERSAL modifier is also specified.

Specifying EFFECTIVE will disable indexed read of the RACF database and switch to full read.

EXPLODE
Values in the column that can be expanded must be expanded.

For the ACL combination field, this requests that all groups are to be expanded into the user IDs connected to the group. In addition, operations access is shown as well as access ALTER-O; the ACL id shows `- oper -` for system operations and the group name for group operations. Whether administrative access is also taken into account depends on the SCOPE modifier (see there).

The EXPLODE output modifier is also used to turn some condensed non-repeated fields into expanded repeated fields, see "Non-repeated field output modifiers: Changing how information is displayed" on page 803.

System-wide operations and access of users with default connections to a universal group will only be taken into account if the UNIVERSAL modifier is also specified.

FIRSTONLY
Reduce the repeated field to its first entry. If SORT is specified too, the expectation is that the repeated field is sorted first and then truncated; support for a combination with SORT on a SUMMARY statement is limited. Since the resulting field is no repeated field, FIRSTONLY cannot be combined with MORE.

HEADER
If there is a non-blank value in the field, an extra line is shown before the line containing the field values. The extra line contains the default header for the field. Header is meant to be used for lines containing only one field (column); the result is not defined otherwise. On an ISPF display, the header is shown highlighted. The header is also shown if the field is modifiable and can be used to add a (new) value.

HORIZONTAL(*entrylength***)**
HOR(*entrylength***)**

The values of a repeated field are to be listed horizontally, for example, multiple values are to be shown on a line. Note that the HORIZONTAL modifier applies locally to a field, so it is not possible to horizontally repeat a combination of two fields from the same repeat group; however, each field can be listed horizontally on its own line using HORIZONTAL, while the '/' newline operator can be used to put each field on its own line.

Normally, the output length for a field can be interpreted as either the length of the output column in the report or the length used to print an entry in that column. When HORIZONTAL is specified, the two are no longer equivalent. Therefore, the entry length can be specified separately between brackets. By specifying entry length 0, the entries may be packed as tightly as possible (though still separated by one blank). When HORIZONTAL is specified **with** brackets, but **without** an entry length between the brackets, the default output length of the field is used as the entry length.

If a WRAP or WORDWRAP modifier is specified in addition to HORIZONTAL, the combination indicates that multiple lines can be used, and furthermore WRAP or WORDWRAP is applied to each repeated field value separately. Effectively, this means that a repeat group entry is only added to the same line within the specified column if it fits completely (including any padding implied in the case of a fixed width entry length). If it does not fit, a new line is added to the column and if it still does not fit, it is (word)wrapped to additional lines.

Deprecated syntax: HORIZONTAL can also be specified without brackets. In combination with WRAP this means that the output length specified or implied is used as the column width (as usual). The entry length cannot be specified in the old syntax and defaults to 0 (tight packing).

If a first HORIZONTAL occurs **without** WRAP, the old syntax will interpret the output length up to that point as the *entry* length and the *column* length becomes 0. This is flagged as confusing syntax by informational message CKR1248 (except for explicit length 0).

If a DEFINE statement contains any HORIZONTAL specification without WRAP and a subsequent use of the variable also specifies HORIZONTAL in the old syntax without WRAP, the following occurs. An output length specification updates the *entry* length, the *column* length is not changed and depends on the preceding DEFINE statement. This is flagged as confusing syntax by informational message CKR1249 (unless both column and entry length are 0).

Example - Using HORIZONTAL with a fixed entry length for an easily readable report

This example shows how to produce an easily readable report for the connect groups of each user. Each connect group name is printed in 8 positions (the default output length of CGGRPNM), and the total report has width 78 (though the line length is 80). Only the first 7 connect groups are shown.

```
newlist type=racf ll=80
 select class=user segment=base
 sortlist key(8,"User") cggrpct cggrpnm(hor(),62)
```

This produces output like the following.

```
P R O F I L E   L I S T I N G   12 Sep 2003 00:07                    page    1

C##ASC3     10 C##A     C##AAPPC C##ARACF C##B     C##BDOC  C##BEPRD C##BTSUP
```

Example - Using HORIZONTAL with column width 0 to fill out the output line

This example shows how to produce an easily readable report for the connect groups of each user. Each entry is printed in 8 positions (the default output length of CGGRPNM). The width of the report depends on the line length (but it is explicitly set to 80 in this case), and as many connect groups are shown as will fit on the line.

```
newlist type=racf ll=80
 select class=user segment=base
 sortlist key(8,"User") cggrpct cggrpnm(hor(),0)
```

Note that column length 0 can be used for the last field on a line to mean the rest of the line.

This produces output like the following.

```
P R O F I L E   L I S T I N G   12 Sep 2003 00:07                    page    1

User     #Conn

C##ATST      1 C##A
```

Example - Using HORIZONTAL with entry length 0 for compact output

This example shows how to pack as many connect groups for each user as will fit on one line.

```
newlist type=racf ll=80
 select class=user segment=base
 sortlist key(8,"User") cggrpct cggrpnm(hor(0),0)
```

This (preferred) syntax is equivalent to `cggrpnm(hor,0)`.

Note that column length 0 can be used for the last field on a line to mean the rest of the line.

This produces output like the following.

```
P R O F I L E   L I S T I N G   12 Sep 2003 00:07                    page    1

               C##CNG   C##CXGRP C##GRACF
C##ATST      1 C##A
```

Example - Using HORIZONTAL with WRAP to print all entries tightly

This example shows how to print all connect groups for each user using as few lines as possible.

```
newlist type=racf ll=80
 select class=user segment=base mask=crma*
 sortlist key(8,"User") cggrpct cggrpnm(hor,wrap,0)
```

This syntax is equivalent to `cggrpnm(hor(0),wrap,0)`.

Note that column length 0 can be used for the last field on a line to mean the rest of the line.

This produces output like the following.

```

```

MORE
This modifier has effect on ISPF displays only. It specifies that the overview panel should show the only value for the field in records where it has only one value, but the text '<more>' or '+' when there are more. It furthermore implies that the field should be shown on both the overview and the display panel, unless one of the general output modifiers DETAIL, NODETAIL or NONDISPL has been specified for the field. (Note that the NEWLIST option DETAIL is ignored.) See also general output modifier BOTH.

NODUP
Duplicates in this repeated field must be eliminated. This modifier implies SORT.

NOSCOPE
This modifier is only effective on the ACL field. It negates the effect of a previous SCOPE modifier (e.g, in a DEFINE AS).

RESOLVE
Values in the column that can be expanded must be expanded, and the duplicate entries deleted until one (arbitrary) entry with the highest access remains, unless a specific, non-expanded entry was present. Access through operations or group operations attributes is not shown.

Currently, the only field where RESOLVE is valid is the ACL combination field. This results in an access list display showing all user IDs and the actual access they have through any access list entry.

Whether administrative access is also taken into account depends on the SCOPE modifier (see there). Access of users with default connections to a universal group will only be taken into account if the UNIVERSAL modifier is also specified.

SCOPE
This modifier is only effective on the ACL field. It requests administrative access to be added to the access list display, if also one of the modifiers EXPLODE, RESOLVE, or EFFECTIVE has been specified. The SCOPE modifier adds access list rows for ownership and access through group-special authority as "OWNER" access and authority on the data set qualifier as "QUALOWN" when EXPLODE is in effect, and causes those extra access list entries to participate in the RESOLVE or EFFECTIVE processing.

SORT
The column must be sorted. This is done by ascending internal value, unless a sort modifier is included between parentheses. The SORT modifier is local to the parameter where it is specified. If you want to display more than one field

of a repeat group and sort them, you should use a supported combination field name (e.g. ACL or CONNECT) to access the repeat group as one column, and/or use indirect reference based on the sorted column. The SORT modifier can be further qualified by a *sort order modifier* enclosed in parentheses immediately behind the SORT output modifier. Two sort order modifiers can always be used: ASCENDINGand DESCENDING. The default is ascending sort order. Three other sort order modifiers are valid only for the ACLand CONNECTS combination fields; these are **USER**to sort on user ID (ascending), **ID** to sort on id in the access list (user or group, ascending),and **ACCESS** to sort on access level (from ALTER to NONE). The default sorting for ACL and CONNECTS is USER. Specifying DESCENDING results in ACCESS. Note that using the DESCENDING output modifier by itself (as opposed to SORT(DESCENDING)) will *not* change the sort order within a repeated field, but will change the record sort order.

Summary statistic modifiers: Changing the output display for SUMMARY operations

In addition to output modifiers, the statistics of a summary command can specify *statistic modifiers* to change the way SUMMARY operates. This modifier is valid on fields of the (D)SUMMARY commands as well as on the DEFINE statement.

NOPROP NP
Do not propagate this statistic to higher levels of the (D)SUMMARY command. This can be used to stop the default behavior of automatically propagating all statistics to higher summary levels if they are not present there yet.

>number <number <=number >=number
A relational operator can be used to indicate a *threshold condition* for the statistic. A summary level is only displayed/listed if all thresholds of the statistics at that level are satisfied. The threshold condition only applies to statistic variables with numeric values.

Instead of defining threshold values using numerals, you can use the SYMBOLIC statement (`SYMBOLIC NUM name=value`) to define a symbolic name for a numeric value. The symbolic name can be used on its own or associated with a numeric default value that is used if the symbolic has not been defined. The default value is specified as `name|value` as shown in the following examples:

```
SELECT NUMBERFIELD>HIGH
SELECT NUMBERFIELD>HIGH|20
```

In the CARLa command input, the symbolic name must be defined before its first use. If you use the conditional specification, the value is the default value that is used only if the SYMBOLIC statement has not been defined. For more information and usage restrictions, see “SYMBOLIC” on page 940.

Modifying the column header

If desired, a *column header* may be defined for the field. Generally the default header is sufficient, but if you use a non-default length, you may also want to use another header. This can be accomplished by specifying a string as modifier; the string must be enclosed in either single, double, or left quotations to distinguish it from an output format name. Possibly, you have to specify a different output length as well, because by default the header is truncated at the implied or specified field output length. The maximum length of the header string is 512 characters.

Changing the sort order

The LIST command produces output in order of processing; the SORTLIST, DISPLAY, and (D)SUMMARY commands produce sorted output. Output is sorted

column by column, from left to right, in ascending order. To compare subsequent output lines, all of the output fields are compared in turn, until a difference is detected. If a column contains a repeat group, only the first field of the unsorted repeat group is taken into account.

The following methods have been provided to change the sort order:

- The DESCENDING output modifier.
- The NONDISPLAY output modifier.
- The SORT output modifier.
- The SEARCHKEY and TREELINE fields in NEWLIST TYPE=RACF.

The DESCENDING output modifier changes the sort order for a column from ascending into descending. All other columns are still sorted in ascending order, and columns to the left are still compared before the current column. This means that using the DESCENDING output modifier in the third column from the left sorts all records in ascending order as determined by the first two columns; if the first two are equal, in descending order as determined by the third column; and if the first three are equal, in ascending order as determined by subsequent columns.

The NONDISPLAY output modifier can be used to 'hide' an output field. The column in which it is used is not displayed, and does not take up space on the screen or in a report. However, the content of the hidden column is still used to determine the sort order. The NONDISPLAY output modifier can therefore be used to specify a sort sequence different from the printed output. It is most often used to hide a first column containing the desired sort key , e.g. SEARCHKEY .

The SORT output modifier is used to sort repeat group entries within a column. It does not affect the overall sort order. See “Repeated field output modifiers: Changing display of Repeated fields” on page 804 for more information.

The SEARCHKEY and TREELINE are two fields that are provided especially to change the sort order. The SEARCHKEY field can be used to sort profile names in a 'natural' order: generic characters follow alphanumerical characters. The TREELINE field can be used to sort GROUP profiles in a sort order useful to create group-tree reports. To sort on either of these fields, use them as the first column, with the NONDISPLAY output modifier (neither field provides 'pretty' output).

Format names for input and output

When you generate commands in CARLa input and specify output options, you must ensure that input and output values have the proper syntax. zSecure provides format names to address this issue.

- “Specifying syntax for RACF command input”
- “Flag formats: Using available formats for flag field input and ouput” on page 826
- “Date output formats: Formatting date field output for different locales and standards” on page 828
- “Formatting UNIX file type, attribute, and audit flag fields” on page 823
- “COMPARE processing output formats: Formatting COMPARE_CHANGES results” on page 829

Specifying syntax for RACF command input: When you generate RACF commands in CARLa output, you must ensure that generated values have the proper syntax yourself. Many report formats have equivalents that start with a '$' character that are suitable for this.

$AsymKeyUsage
This formats the ASYMUSAGE(CSFAUSE) field as used in RACF commands RDEFINE and RALTER for the following general resource classes: CSFKEYS, GCSFKEYS, XCSFKEY, and GXCSFKEY segment ICSF.

$CFSYN
Format to generate the FIRST and OTHER syntax specification for a RDEFINE and RALTER for general resource class CFIELD segment CFDEF. You must add the key, class, and segment parameters yourself.

$CUSTOM_DATA
Format to generate the CSDATA part of an ADDUSER, ALTUSER, ADDGRP, or ALTGRP command. The format prints the CSKEY followed by the CSVALUE in parentheses. You must add the key and segment parameters yourself. This format is only valid on the CUSTOM_DATA field.

$SymKeyExp
This formats the SYMEXPORTABLE (CSFSEXP) field as used in RACF commands RDEFINE and RALTER for the following general resource classes CSFKEYS, GCSFKEYS, XCSFKEY, and GXCSFKEY segment ICSF.

ACCESS
Access level. The usual access levels are NONE, EXECUTE, READ, UPDATE, CONTROL and ALTER. For connects the access levels JOIN, CONNECT, CREATE and USE may be shown. For digital certificates this field may show the TRUST or NOTRUST status. In certain reports, or exploded/resolved/effective/trust access lists the special values OWNER, QUALOWN, CREATE, ALTER-M, ALTER-P, CKGOWNR, READLPA, LOADEXE, COPY, AUDIT and HIDDEN may occur. On an ACL field expanded with the EFFECTIVE or EXPLODE modifier ALTER-O may be shown.

ACLACCESS
Only valid for the ACL field or a subselect thereof. This format displays just the access level, optionally followed by a condition in parentheses: READ or READ(PROGRAM=CKRCARLA). It is meant for use with a define subselect ACL variable that selects a specific ID, * for example.

ACLID
Only valid for the ACL field or a subselect of this field. For each ACL entry, this format displays an ID in the output, optionally followed by a condition in parentheses. If the ACL is in normal format, the ID is the value of ACL id. If the ACL uses field modifiers like EXPLODE or EFFECTIVE, the ID is the value of the resolved user ID. The ACLID format is designed to format the output for a DEFINE SUBSELECT ACL variable that selects a specific access level. See also "ACLVIA."

ACLIDACCESS
Only valid for the ACL field or a subselect of this field. This format displays the ID followed by the access level and optionally a condition in parentheses. It is meant to display an access list in horizontal wrapped format.

ACLVIA
Only valid for the ACL field or a subselect of this field. This format generates output that is like the default ACL format, except that the first two columns of data, User and Access, are omitted. In other words, only the ACL ID and an optional condition (When) are shown. See also "ACLID."

ACSI
Filemode access intent. Formats a flag field in a 4-character field corresponding

with the UNIX_ACCESS_INTENT field, for example,*drwx*. See "UNIX_ACCESS_INTENT" on page 1375.

ADDRESS
Formats both 31-bit and 64-bit addresses. 31-bit addresses are printed as 8 hexadecimal characters, 64-bit addresses are printed as two blocks of 8 hexadecimal characters, separated by an underscore.

AFC
Audit function code. Formats a USS Audit function code in a 16-character field corresponding with the UNIX_FUNCTION field documented in "SMF: SMF records" on page 1276. A sample value of the field is 'unquiesce_setuid'. If the meaning of some function code *nnn* is (yet) unknown, it will be formatted as `AFC_nnn`.

ASIS
The field is copied without modification. The difference with CHAR is that trailing blanks are preserved. Note that with XML output, trailing blanks (as well as trailing null characters) are trimmed off anyway.

AUDAC, AUDLVL
Audit access level, for example the access level at which auditing starts. Can be blank, READ, UPDATE, CONTROL or ALTER.

AUDIT
Audit type, for example indication which accesses are logged. Can be ALL, SUCCESS, FAILURE, or NONE.

AUTHORITY
Connect authority. Can be USE, CREATE, CONNECT, or JOIN.

BLANK$HDR
Blank or header. Format a flag field as blanks if true or missing and as the header otherwise. An overriding length and header are generally required. See also HDR$BLANK.

BLANK$NO
Blank or no. Format a flag field as blanks if true or missing and as "No" otherwise.

BLANK$STR(*'string'***)**
Blank or string. Format a flag field as blanks if true or missing and as the specified string otherwise. An overriding length and header are generally required. The string can be enclosed in single, double, or left quotation marks. See also STR$BLANK.

CATEGORY
Security category in words. This format is invalid in a LIST statement. If the word value is unavailable, it displays the internal decimal value as <*nn*>. Maximum output length: 37 characters.

CHAR
Character string. The field is copied without modification, except that trailing blanks are not preserved. See also ASIS.

CHR$NOFF
This format is designed to handle character fields that are defined with a default value of x'FF'. This means a blank field is printed if every byte of the field contains x'FF', in any other case, the field is printed as is.

CMDAUTH
This formats a console command authorization in a 6-character field. It can be MASTER, ALL, INFO, or a combination of the letters C I S for CONS, IO, and SYS respectively.

CONNECTID
Only valid for the connects field or a subselect thereof. Prints a connect id from a subselect connects variable or a connects field as "id". It is meant for use with modifiers horizontal, word wrap.

CONTENTS, STRINGS
Print binary data in a condensed human-readable format. A sequence of consecutive printable characters is considered a text string when it has at least three characters or if it occurs at the end of the data. Text strings are printed. Data not part of a text string is condensed. A residual sequence of two or more characters is replaced by two dots. A residual single unprintable character is replaced by a single dot. See also PRINTABLE.

CONVSEC
Conversation security. Can be NONE, CONV, AVPV, PERSISTV, or ALREADYV.

CSVALUE
Value of a custom field. This setting formats the value of the custom field depending on its type. This format is only valid on the CUSTOM_DATA field.

DATE
Date is displayed in various formats. The basic layout is 11 characters long DD MMM YYYY (" 1 Jan 1997"). The layout is determined by the output length specified, as shown in the next section.

DATETIME
This formats a TIME BIN time stamp (CCYYDDDF + 4 byte centiseconds) as DD MMM YYYY HH:MM:SS.CC (12 Jan 1980 12:23:34.89)

DATETIMEZONE
This formats a TIME BIN time stamp (CCYYDDDF + 4 byte centiseconds) as YYYY-MM-DD,HH:MM:SS.D, *sign* HH:MM (e.g., 2003-1-26,13:30:15.0,-4:0). Since the time zone is not present in the input, it is taken from the system the input is associated with. For a DEFTYPE NEWLIST this requires a DEFINE for the field SYSTEM, which is interpreted as an SMF ID which is matched against the available CKFREEZEs (preferably in the same complex if the DEFTYPE allocation specified one). If the lookup fails, the time zone is taken from the default system (see “DEFAULT SYSTEM” on page 750). On a SUMMARY or for a BUNDLEBY variable the time zone is omitted. If the input length is not 8, the automatic time zone is disabled.

If the input field has a 12-byte value, the additional 4 bytes are interpreted as the high half of a TOD stamp. The parser might still issue CKR1228 or CKR1229 in advance to warn you when the automatic lookup is not supported. Add the CARLa command SUPPRESS MSG=(1228,1229) before your query to get rid of the warnings.

The intent of the output format is to be compliant with RFC 2579.

DATE$STR (*'string'***)**
Date or string. This format allows the user to specify a string to be returned when a date field has no value. The string can be enclosed in single, double, or left quotation marks. A valid date is displayed according to the basic date format. See also `DATE`.

DEC
DECIMAL
Decimal. This format accepts a 1, 2, 3 or 4-byte source integer. If it is a 4-byte integer and contains high-value bits only (X'FFFFFFFF), this is interpreted as *undefined* and nothing is printed. However, a 1-byte source value of 255 is printed as 255. If a 4-byte value is defined but has its most significant bit on, this is considered an error. If the number to be printed does not fit in the specified or implied column width, asterisks are printed (*). Note that a 1-byte value can always be printed in 3 positions, 2-byte in 5, 3-byte in 8, and 4-byte in 11. See also NUM.

DEC$ABBREVIATE
DEC$ABBR
This functions as the DEC format, but will abbreviate the number to fit into the specified or implied column width. It does so by dividing the number by powers of 10 (rounding normally), and inserting the appropriate SI multiplication factor (k, M, G, T, P, or E). For example, the number 10485760 is printed in a 4-character column as 10M5 and in a 6-character column as 10486k. Note that a minimum column width of 42-characters is needed for this format to work correctly. The value *0* is not printed, but blanks will be shown instead.

The format accepts source integers of up to 8 bytes. If the source integer has 4 or 8 bytes and it contains high-value bits only (X'FFFFFFFF' or X'FFFFFFFFFFFFFFFF'), this is interpreted as undefined and nothing is printed. Other 4-byte and 8-byte integers with a most significant bit of 1 are considered to be errors. Source integers with a length other than 4 or 8 are always interpreted as nonnegative integers. They are neither interpreted as undefined, nor considered to be errors.

DEC$BLANK DB
Decimal or blank. This functions like DEC, but displays blanks if the value is 0.

DEC$NO
This functions as the DEC format, but displays 'No' if the value is 0.

DOM
Delete Operator Message format. Can be blank, NORMAL, ALL, or NONE.

DSTYP
DSTYPE
Data set type. Can be blank, NONVSAM, GENERIC, VSAM, MODEL, TAPE or "n/a". Use this format to display the DSTYPE field from DATASET profiles.

DUMP
DUMP(*n*)
Dump format: *oooo. xxxxxxxx xxxxxxxx xxxxxxxx xxxxxxxx *ccccccccccccccc** (offset in hexadecimal, contents in hexadecimal per fullword, contents as text with dots for nonprintables.). By default, the offset is shown as 4 hexadecimals; this number can be varied by specifying DUMP(*n*) for n hexadecimals. If n is 0, the separating dot and blank are suppressed. The dump format always displays an integer number of fullwords per line. With a default offset display, it requires a minimum effective output length of 21 (for 1 fullword), and 13 more positions per additional fullword; if the output length is smaller than the minimum length required to print one fullword, one asterisk(*) is printed. The default output length allows four fullwords to be printed (this number is 60 for a default offset display). This length is also selected if 0 is specified or implied. The WRAP (and WORDWRAP) modifiers are automatically implied and have no further effect; the HORIZONTAL modifier is flagged as an error.

EUDATE
This formats a date in European format. It returns the 10-character value 'DD-MM-YYYY'. If not enough space is available only the last 2 digits of the year will be shown. It is possible to override the separator to a / or a blank as follows: EUDATE('/') or EUDATE(' ').

EXTATTR
UNIX file extended attributes, e.g., 'apsl'. See "Formatting UNIX file type, attribute, and audit flag fields" on page 823.

FILEAUDIT
UNIX file audit flags. This parameter formats one set of audit flags (user, auditor, effective) for a UNIX file. as e.g. 'sfa' (*read successes*, *write failures*, *all executions*). See "Formatting UNIX file type, attribute, and audit flag fields" on page 823.

FILEMODE
UNIX file access flags. This parameter formats the access values *read*, *write* and *execute* for the owner, group, or other ID, rwxr-x--- for example. See "Formatting UNIX file type, attribute, and audit flag fields" on page 823.

FILETYPE
UNIX file type. '-' (regular file), 'b' (block special file), 'c' (character special file), 'd' (directory), 'e' (external link), 'l' (symbolic link), 'p' (pipe), 's' (socket). See "Formatting UNIX file type, attribute, and audit flag fields" on page 823.

FLAG
Format a flag field as "YES" if true, as blanks if false or missing and as '???' if unintelligible.

FLAG2NICE
This flag format displays true as "Yes", false as "No", missing as blanks and errors as '?'. FLDLEN This displays the length of the field as it is stored in the database (except for special keywords, where it generally returns the length of the external representation). If the field length to be printed does not fit in the output column width asterisks (*) are printed.

GID
Unix group id. Formats a UNIX group id as a signed decimal number, possibly followed by one of the associated RACF groupids between brackets. The decimal number can also be followed by '(undef)'. A sample value is '9000 (AGROUP)'.

HDR$BLANK
HB
Header or blank. Format a flag field as the header if true and as blanks otherwise. An overriding length and header are generally required. See also BLANK$HDR.

HEX
Hexadecimal. As a hexadecimal display requires twice as many output positions as the length of the input, an overriding length is generally required. Length 0 is recognized as 'natural length' (for example, twice the field length), but does not work with DISPLAY. If WRAP is also specified, output behavior with respect to output length follows the WRAP rules rather. If HEX,WRAP,0 is specified, the actual output length is rounded down to a byte boundary (even number), except for length 1. See also DUMP.

IP

This format takes either a 4 byte IPv4 address or a 16 byte IPv6 address and prints it as follows. A four byte address is printed as four decimal numbers separated by periods, `10.0.2.255` for example. For a 16 byte address each 2 byte block is printed in hex, dropping leading zeroes, separated by colons, `FE80:0:0:0:200:F8FF:FE01:9742` for example. This is compressed by removing the longest string of 2byte zero blocks as follows: `FE80::200:F8FF:FE01:9742`. Compressed addresses that do not fit the destination length will print the longest possible suffix (in 2 byte blocks) preceded by an asterisk, `*F8FF:FE01:9742` for example.

IPSQ
Formats IP addresses in the standard IP address format except that IPv6 addresses are enclosed in square brackets, `[ABCD::9876]` for example. The brackets are added to avoid confusion when an IPv6 address specification is followed by a colon and a port number, `ABCD::9876:1234` for example. When the brackets are added, it is easier to distinguish the port number from the IP address: `[ABCD::9876]:1234`.

IPV4OR6
This formats IP addresses in the standard IP address format, except that addresses of the form `::FFFF:a.b.c.d` are printed like `a.b.c.d`. This format can be useful in a context where `::FFFF:a.b.c.d` denotes a true IPv4 address rather than an IPv4-mapped IPv6 address.

IPV4OR6SQ
This formats IP addresses in the same way as the `IPSQ` format does, except addresses of the form `::FFFF:a.b.c.d` are printed like `a.b.c.d`, without enclosing square brackets. This format can be useful in a context where `::FFFF:a.b.c.d` denotes a true IPv4 address rather than an IPv4-mapped IPv6 address.

JULDATE
JULIANDATE
This formats a date in Julian format, `YYYY/DDD` for example.

KEYUSAGE_RACF
This formats the CERTIFICATE_KEYUSAGE field as RACF interprets it. When combined with the EXPLODE modifier it shows the following values as separate entries in a repeated field: HANDSHAKE, DOCSIGN, DATAENCRYPT and CERTSIGN. When used without EXPLODE it will represent each of these values with a single character (e.g., 'HDEC').

KEYUSAGE_X509
This formats the CERTIFICATE_KEYUSAGE field as defined by the X.509 standard. When combined with the EXPLODE modifier it shows the following values as separate entries in a repeated field: `digitalSignature`, `nonRepudiation`, `keyEncipherment`, `dataEncipherment`, `keyAgreement`, `keyCertSign`, `cRLSign`, and `encipherOnly`. When used without EXPLODE, this setting represents each of these values with the two characters, `dSnRkEdEkAkCcSeO` for example.

L1ASIS
This format copies input strings to the output prefixed by a length byte. Trailing blanks are preserved. This format can be used to create file output. For example, in zSecure Admin, this format is used to create the output file in the Access Monitor consolidation process. L1ASIS is usually used with overriding length 0. Also, see the L1CHAR format name.

The formats L1CHAR and L1ASIS sort on field length before sorting on the character content of the field.

L1CHAR
This format performs the same function as L1ASIS, except that trailing blanks are not preserved.

The formats L1CHAR and L1ASIS sort on field length before sorting on the character content of the field.

LOGDAYS
This formats a byte according to the setting for `logon-allowed` days, in the form SMTWTFS, where the day-of-week letter indicates that logon is *permitted*, and is left blank otherwise. This format can also be used with the EXPLODEoutput modifier and an overriding length of 3; in that case, the first seven bits in the byte are each exploded to 'YES' if set or 'NO' if not set.

LOGTIME
This formats a `logon-allowed` time frame as HHMM:HHMM, blanks, or ANYTIME.

LOWERCASE
Format a string into all-lowercase characters, e.g. '*Ad Grant*' is formatted as '*ad grant*'. Strings longer than 256 bytes are truncated.

MFORM
This formats a message format in a 5-character field. It can be a combination of the letters TSJMX for displaying time stamp, originating system, job ID/name, message text, and excluding exempt messages, respectively.

MONITOR
This formats a message monitor status in a 5-character field. It can be a combination of the letters JtStF. 'J ' and 'Jt' are displayed for JOBNAMES and JOBNAMEST respectively, 'S ' and 'St' for SESS and SESST, respectively. 'F' is displayed for STATUS.

MONTH
The month as a text string: 'January' to 'December'.

MONTHDAY
This formats the day of the month in a date as two digits where the first might be blank as in ' 1' to '31'.

MSGLEVL
This formats a console message level from the RACF field OPERLEVL in the OPERPARM segmentin a 14 character field. The first 12 characters can be ALL or a combination of the letters R I CE E IN. The last two characters are NB or blank. The meaning of the letters is:

NB
No broadcast messages

ALL
Same as R I CE E IN

R Messages requiring an operator reply

I Immediate action messages

CE
Critical Eventual action messages

E Eventual action messages

IN
Informational messages

MVSMSGLEVEL
This formats a console message level from the z/OS EMCS console definitions in a 14 character field. The first 12 characters can be ALL or a combination of

the letters R I CE E IN. The last two characters are NB or blank. The meaning of the letters can be found in the description of the MSGLEVL format.

NOSORTLIST
This modifier can be used to prevent this column to be part of the record sort key as defined by the SORTLIST or SUMMARY command. It is however more efficient CPU wise to use "field(nondispl)" in front of the visible fields to identify sort keys. On the other hand, it makes for convenient and less complex CARLa coding.

NUM
This formats a 1, 2, 3, or 4-byte binary integer as a decimal number with a field name-dependent length. The length can be overridden. If the value contains a high-value (all bits on), blanks are displayed (this is the RACF database value for 'undefined') . To format high-values as a number, use the DEC format.

OCTAL
UNIX file access flags in octal notation, e.g. 0750. See “Formatting UNIX file type, attribute, and audit flag fields” on page 823.

OPERUND
OPERparm
Receive undeliverable messages format (UND). This flag format displays true as "YES", false as "NO", missing as blank and errors as "?". As an input format it is specially suited for the OPERUD template field - see “Flag formats: Using available formats for flag field input and ouput” on page 826.

PGMRNAME
Print the field in character format. This format is specially designed for the `pgmrname` field in the RACF user profiles. If the field contains the RACF default value for the `pgmrname` (20 # symbols), the value is output as blank characters.

PORT
Format a numeric IP port textually. The port descriptions are taken from the Internet Assigned Numbers Authority (IANA). See http://www.iana.org/assignments/port-numbers. You can use this format with DSTPORT and SRCPORT in SMF NEWLIST.

PRINTABLE
Print binary data in a human-readable format. Each unprintable character is replaced by a dot. See also CONTENTS.

RACFLEVEL
This format is meant for use with the RCVT_RACFLEVEL field. It takes a RACF software level like '2060' or '7705' as input, and formats it with dots, like '2.6.0' or '7.7.5'.

RESFLG
This displays the RESFLG flag field of a general resource profile in a 3 character field, in the form SAT. The character S indicates a TAPEVOL that might contain only one data set (singledsn); the character A indicates an automatic TAPEVOL; the character T indicates a TVTOC is maintained. A blank indicates the option is not set. This format can also be used with the EXPLODE output modifier and an overriding length of 11, e.g. RESFLG(EXPLODE,11). When exploded, the options are displayed in full, for example AUTOMATIC/NOAUTOMATIC, SINGLEDSN/NOSINGLEDSN, and TVTOC/NOTVTOC.

ROUTCDE
This formats a routing code bitstring as a list of routing codes ranges, separated by commas.

SECLEVEL
Security level in words. This format is invalid in a LIST statement. If the word value is unavailable, it displays the internal decimal value as <*nn*>. Maximum output length: 38 characters.

SECURPASS_DATE
This formats the date field, as found in SECURPASS SMF records.

SECURPASS_RC
This prints the return code as found in a SECURPASS SMF record as a human readable string, explaining the result.

SECURPASS_REQUEST
This prints the request code as found in a SECURPASS SMF record as a human readable string, explaining type of request.

SIGNEDDEC
Signed Decimal. This format accepts a 1, 2, 3, or 4-byte signed integer and prints it decimally, optionally preceded by a minus sign. If the value to be printed does not fit in the specified output length, asterisks are printed instead.

SLKEY_COMPACT
This format is only valid on the CICS_RSLKEY and CICS_TSLKEY pseudofields in NEWLIST type RACF. Instead of printing each Security Level Key individually, as is done normally for those fields, it combines them into continuous ranges. For example a list of keys like '12 13 14 15 23 35 36 37' will be printed as '12:15 23 35:37'.

SMFTIME
Format a binary 4-byte time value in 1/100s (e.g., from an SMF record) as a time. The maximum output length of this field is 11 characters (formatted 'HH:MM:SS.CC'), other output lengths are 8 ('HH:MM:SS'), 5 ('HH:MM') and 4 ('HHMM', valid for CARLa select statement input). Other lengths revert to the largest of these that can be accommodated, blank-padded, with the exception of length 10 which uses the longest format but truncates; lengths smaller than 4 use 'HH:MM' but truncate.

SMFTIMESTAMP
This formats an SMF time stamp, containing both date and time as DD MMM YYYY HH:MM:SS.CC (12 Jan 1980 12:23:34.89)

SMFTIMESTAMPZONE
This formats an SMF time stamp (4 byte centiseconds + CCYYDDDF) as YYYY-MM-DD,HH:MM:SS.D,*sign*HH:MM (e.g., 2003-1-26,13:30:15.0,-4:0). Since the time zone is not present in the input, it is taken from the system the input is associated with. For a DEFTYPE NEWLIST this requires a DEFINE for the field SYSTEM, which is interpreted as an SMF ID which is matched against the available CKFREEZEs (preferably in the same complex if the DEFTYPE allocation specified one). If the lookup fails, the time zone is taken from the default system (see “DEFAULT SYSTEM” on page 750). On a SUMMARY or for a BUNDLEBY variable the time zone is omitted. If the input length is not 8, the automatic time zone is disabled.

If the input field has a 12-byte value, the additional 4 bytes are interpreted as the high half of a TOD stamp. The parser might still issue CKR1228 or CKR1229 in advance to warn you when the automatic lookup is not supported. Add the CARLa command SUPPRESS MSG=(1228,1229) before your query to get rid of the warnings. STR$BLANK

STR$BLANK(*'string'***)**
String or blank. Format a flag field as the specified string if true and as blanks

otherwise. An overriding length and header are generally required. The string can be enclosed in single, double, or left quotation marks. See also BLANK$STR.

TIME
Format an unsigned packed decimal 4-byte time value in 1/100s (e.g., from a RACF profile) as a time. The maximum output length of this field is 11 characters (formatted 'HH:MM:SS.CC'), other output lengths are 8 ('HH:MM:SS'), 5 ('HH:MM') and 4 ('HHMM', valid for CARLa select statement input). Other lengths revert to the largest of these that can be accommodated, blank-padded, with the exception of length 10 which uses the longest format but truncates; lengths smaller than 4 use 'HH:MM' but truncate.

TOD
This formats a TOD time stamp as DD MMM YYY HH:MM:SS.uuuuuu (12 Jan 1980 12:23:34.897654)

TSOOPT
This formats TSO logon options in a 4-character field. It can be a combination of the letters MNRO for MAIL, NOTICE, RECOVER and OIDCARD, respectively.

UDEC
This format takes a hexadecimal number of up to 8 bytes in length and prints it as an unsigned decimal number.

UDEC$ABBREVIATE
UDEC$ABBR
This format takes an unsigned integer of up to 8 bytes in length and prints it as an unsigned decimal number. The value is abbreviated to fit into the specified or implied column width based on the following calculation: The number is divided by powers of ten (rounding normally), and the appropriate SI multiplication factor is inserted (`k`, `M`, `G`, `T`, `P`, `E`, or `Z`). For example, the number 10485760 is printed in a four-character column as *`10M5`*. In a six-character column, the value is printed as `10486k`.

This format requires a column that is at least 2-characters wide to work correctly.

UID
UNIX user ID. Formats a UNIX user ID as a signed decimal number, possibly followed by one of the associated RACF user IDs between brackets. The decimal number also might be followed by `(undef)`. A sample value is `10002 (SOMEUSER)`.

UPPERCASE
Format a string into all-uppercase characters, e.g. 'Ad Grant' is formatted as 'AD GRANT'. Strings longer than 256 bytes are truncated.

UPT
This formats a TSO user profile table in a 15 character field. It consists of the user prefix (7 characters), a blank, and a combination of the letters PI?MOWR for PROMPT, INTERCOM, PAUSE, MSGID, MODE, WTPMSG, and RECOVER, respectively.

USDATE
This formats a date in US format. It returns the 8-character value 'MM/DD/YY' even if the year is beyond 2000, for use by applications that work this way.

USRDATA
Format to print only the USRDATA from the USR field.

WEEKDAY
The day of the week as a text string: 'Sunday' to 'Saturday'.

WHEN
This formats a condition in the template field ACL2RSVD in the form:*class profile*.

XSD_DATETIME
This format is intended to print XML-compliant time stamps according to ISO 8601. In an XML schema this is represented as "xsd:dateTime", or in the older (1999) specification "xsd:timeInstance". The format lists as YYYY-MM-DDTHH:MM:SS.CC+hh:mm where the time zone is left out if unknown. All numbers print with leading zeroes, for example, subfield offsets are fixed within this format.

YEAR
This formats the year of a date value in 4 digits.

YESNO
Yes or No (mixed case). This flag format displays true as "Yes", false and in error as "No", and missing as blanks. It can also be used with the EXPLODE output modifier; in that case, all 8 bits in a byte are exploded to the value "Yes" or "No".

$ACL
Format to generate the trailing part of a RACF PERMIT command that contains the ID, ACCESS, and WHEN parameters. You must add the profile key and CLASS parameter yourself. The format can only be applied to the field name ACL.

$AUDITLVL
Format to generate the AUDIT or GLOBALAUDIT parameters for an ALTDSD or RALTER command. It can only be applied successfully to the fields AUDITLVL and GAUDITLVL.

$CASE
This flag format displays true as "ASIS", false and in error as "UPPER", and missing as blanks. It can be used for formatting the CASE subparameter of the CDTINFO parameter of an RDEFINE or RALTER command.

$CHAUDIT
UNIX file audit flags command format for use with the**chaudit** command, e.g., 'r=s,w=f,x=sf' (read successes, write failures, all executions). See “Formatting UNIX file type, attribute, and audit flag fields” on page 823.

$CHMOD
UNIX file access flags command format for use with the **chmod** command, e.g., 'o=,u=rwx,g=rx' (user read/write/execute, group read/execute, other no access). See “Formatting UNIX file type, attribute, and audit flag fields” on page 823.

$CMDAUTH
Format to generate the string to be included between parentheses in the AUTH subparameter of the OPERPARM parameter of an ADDUSER or ALTUSER RACF command. $CONDQT

$CONDQT
Format to print a field normally or in quotations depending on the contents. If the string contains a comma, semicolon, parenthesis, or blank, a quoted string is printed. If the string is printed in quotations, all occurrences of a quotation are doubled.

$CONNECT
Format to generate the trailing part of a RACF CONNECT command containing the AUTH, UACC, SPECIAL, OPER, AUDITOR, ADSP, GRPACC, REVOKE, REVOKEDT, and RESUMEDT parameters. You must add the user ID and GROUP parameter yourself. The format can only be applied to the field name CONNECT.

$DATE
Format to generate the ISO standard date format YYYY-MM-DD.

$DOM
Format to generate the string to be included between parentheses in the DOM sub-parameter of the OPERPARM parameter of an ADDUSER or ALTUSER RACF command.

$EXTATTR
UNIX file extended attributes command format for use with the extattr command, for example, '+as,-pl' (APF authorized, share address space might be honored). See “Formatting UNIX file type, attribute, and audit flag fields” on page 823.

$LOGCMDR
Format to generate the string to be included between parentheses in the LOGCMDRESP sub-parameter of the OPERPARM parameter of an ADDUSER or ALTUSER RACF command.

$LOGDAYS
Format to generate the content of the 'when(days())' parameter for generating an ALTUSER, ADDUSER, RALTER, or RDEFINE command.

$LOGTIME
Format to generate the content of the 'when(time())' parameter for generating an ALTUSER, ADDUSER, RALTER, or RDEFINE command.

$LOGZONE
This formats a 3 byte packed decimal RACF time zone (0HHMMS) as "W HH.MM"/"E HH.MM". This is intended for the creation of commands in the TERMINAL General Resource class, in the TIMEZONE field.

$MEMLST
Format to generate the string to be included between parentheses of the ADDMEM operand of the RDEF and RALTER command.

$MFORM
Format to generate the string to be included between parentheses in the MFORM sub-parameter of the OPERPARM parameter of an ADDUSER or ALTUSER RACF command.

$MONITOR
Format to generate the string to be included between parentheses in the MONITOR sub-parameter of the OPERPARM parameter of an ADDUSER or ALTUSER RACF command.

$MSGLEVL
Format to generate the string to be included between parentheses in the LEVEL sub-parameter of the OPERPARM parameter of an ADDUSER or ALTUSER RACF command.

$NO
Command generation for No. Format a flag field as blanks if true or missing and as "no" otherwise. It is meant for generating RACF command parameters

like SPECIAL/NOSPECIAL. This format can also be used with the EXPLODE output modifier; it gives identical results.

$QUOTED
Format to print a field while doubling all occurrences of a single quote. You must supply the leading and the trailing quotation yourself.

$RACLINK
Format to generate the DEFINE or APPROVE keywords and parameters for use in a RACLINK command. The $RACLINK format can only be used to format the RACLINK field of the USER profile, and does not include the user ID itself.

The full RACLINK command can be used to recreate a RACLINK association. In addition to the required keywords, the $RACLINK format can generate comments indicating the status of the RACLINK association at hand.

- `/* Unknown link type */` The link type is not PEER, MANAGER OF, or MANAGED BY,
- `/* Master */` The link type is MANAGED BY,
- `/* Reserved bit used */`
- `/* Rejected */`
- `/* Pending on local node */`
- `/* Pending on remote node */`

$RESFLG
Format to print the RESFLG field of a general resource profile for a RDEFINE or RALTER command.

$RETPD
This formats a two byte hexadecimal number as a RACF retention period. This intended for the creation of commands in the DATASET class, in theRETPDfield.

$SYN
This format displays the syntax rules of profiles as a list of text strings: "ALPHA", "NATIONAL", "NUMERIC", and, "SPECIAL". It can be used for formatting the FIRST and OTHER subparameters of the CDTINFO parameter of an RDEFINE or RALTER command.

$TIMEOUT
Format to print the TIMEOUT field of the CICS segment of a user profile for a RDEFINE or RALTER command.

$USRDATA
Format to print the USR field in a format suitable to generate a CKGRACF USRDATA command, for example *index(value)*.

$XRFSOFF
Format to generate the string to be included between parentheses in the XRFSOFF subparameter of the CICS parameter of an ADDUSER or ALTUSER RACF command.

$YESNO
Command generation Yes or No. This flag format displays true as 'YES', false and in error as "NO" and missing as blanks. It is meant for generating RACF command parameters like MIGID(NO). This format can also be used with the EXPLODEoutput modifier; in that case, all 8 bits in a byte are exploded to the value 'YES' or 'NO'.

Formatting UNIX file type, attribute, and audit flag fields: This section provides overviews of various output formats used with the UNIX file system.

Specifically, we look here at the formats for file type, attributes, extended attributes and audit flags.

When you issue the **ls** command from a standard OMVS shell with the **-laEW** options, you obtain a listing (somewhat) like the following:

```
total 40
drwx------+ fff---      2 C##BJT2  C##BOMVS    8192 Jan 25 13:33 .
dr-xr-xr-x  ------     38 R##SLIN  SYSAPPL        0 Jan 25 14:52 ..
-rwxr-----  fff--- --s  1 C##BJT2  C##BOMVS     749 Jan 25 13:48 .profile
-rw-------  fff--- --s  1 C##BJT2  C##BOMVS     286 Jan 25 16:42 .sh_history
```

The leftmost column shows the file type in the first position (TYPE), the file's attributes (ATTR), and whether the file has any (extended) ACL entries. The second column shows the audit flags (AUDITFLAGS_USER, AUDITFLAGS_AUDITOR). The third column shows the file's extended attributes (EXTATTR). The other columns show the number of hard links to the file (LINK_COUNT), the owner (OWNER), the group (GROUP), the file size, the last change date (for a file; for a directory the creation date), and the pathname. The field names shown in brackets refer to NEWLIST TYPE=UNIX.

There are three different types of ACLs that can be associated with a UNIX file: an access ACL (EXTENDED_ACL), a directory default ACL (DIRECTORY_DEFAULT_ACL) and a file default ACL (FILE_DEFAULT_ACL). The last position of the first column corresponds with the OR of these three, which can be defined as follows.

```
DEFINE TYPE=UNIX ANY_ACL TRUE WHERE EXTENDED_ACL OR,
                                DIRECTORY_DEFAULT_ACL OR FILE_DEFAULT_ACL
```

File type: The following table list the possible file type values (FILETYPE format).

TYPE	file type	meaning
-	regular file	contains data
b	block special file	e.g., a disk or CD-rom (but this does not occur in USS)
c	character special file	e.g., a tty or printer
d	directory	contains files
e	external link	is a UNIX name for an MVS data set, or a PDS(E) member
l	symbolic link	contains another UNIX pathname to look up instead
p	pipe (or FIFO)	is a FIFO communication stream between two programs
s	socket	is a network connection

Note that 'hard link' is not a file type. In UNIX a file does not really have a name but is identified by an inode number. A file is primarily referred to via one or more path names (known as *hard links*) where that `inode` number appears in the directory.

The preceding example listing shows two directories and two regular files.

File attributes: Standard access control to the file is provided via the OWNER and GROUP in combination with the attributes. The attributes form three groups, the first of which shows the access the OWNER has, the second the access the other members of the GROUP have, and the third the access anyone else has. Each group consists of three positions. The first position shows whether read access is permitted (r), the second whether write access is permitted(w), and the third whether execute access is permitted(x).

In the preceding example listing, the .profile file can be read, written and executed by C##BJT2, and read by the other members of group C##BOMVS; other access is not permitted. The parent (..) directory of the one listed in the example can be read and executed by anyone, but no one has write access to it.

Furthermore, the third positions in the three groups are used to show whether the file has the setuid property, the setgid property and/or the sticky bit property, respectively. The setuid and setgid property are shown as 's' (when combined with execute access, or as 'S' without it), the sticky bit is shown as 't' (when combined with execute access, or as 'T' without it).

If a file has the setuid or setgid property, this means that when it is executed, it does not run under the effective permissions of the user/process executing it, but changes to those of the OWNER or GROUP associated with the file, respectively.

For a regular file, the sticky bit causes on execution a search for the program in the user's STEPLIB, the link pack area, or link list concatenation. For a directory, the sticky bit allows files in a directory or subdirectories to be deleted or renamed only by the owner of the file, by the owner of the directory, or by a superuser.

If a file has an (extended) access ACL, there are additional users and groups that have access. The file owner takes precedence over user entries on the ACL, which are more important than any group entries. All group entries (owning group or ACL) are equal, and if any group gives you access, you have that access. The file default ACL is copied to files created in a directory, and likewise the directory default ACL becomes the access ACL of a subdirectory when it is created (both default ACLs are also copied as default ACLs to the subdirectory).

The default output format for the ATTR and PHYSICAL_ATTR fields, FILEMODE, formats the access control bits like **ls**. There are two other output formats suited for these fields, OCTAL and CHMOD.

OCTAL	Permission	FILEMODE	CHMOD
4000	Setuid	--S------	go=,u=s
2000	Setgid	-----S---	uo=,g=s
1000	Sticky bit	--------T	ug=,o=t
0400	Owner can read	r--------	go=,u=r
0200	Owner can write	-w-------	go=,u=w
0100	Owner can execute	--x------	go=,u=x
0040	Group can read	---r-----	uo=,g=r
0020	Group can write	----w----	uo=,g=w
0010	Group can execute	-----x---	uo=,g=x
0004	Other can read	------r--	ug=,o=r
0002	Other can write	-------w-	ug=,o=w

OCTAL	Permission	FILEMODE	CHMOD
0001	Other can execute	---------x	ug=,o=x

The CHMOD format, refers to the three groups (owner, group and other) of the FILEMODE mode format with the letters 'u' (user), 'g' (group) and 'o' (other). It lists for each group what permissions are set by enumerating them, for example u=rwxs (owner may read, write, and execute, and the setuid property applies). If more groups have the same attributes, it lists them once, for example go= (group and other have no access). It separates different access indications with commas. The output can be used in a **chmod** command to restore a file to those permissions.

Audit flags: The audit flags indicate the auditing requested by the user and auditor, in two groups of three positions (for the access types read, write and execute). Each position shows one of the indications '-' (no auditing), 'f' (failure auditing), 's' (success auditing) or 'a' (both failures and successes). The effective audit settings are the requests of the user and auditor combined.

The CHAUDIT format refers to the three access types as 'r' (read), 'w' (write), and 'x' (execute). It lists for each what attempts are audited, by enumerating them, e.g., r=sf (for read access both successes and failures are audited). If more access types have the same audit settings, it lists them once, e.g., wx=f (for write and execute access only failures are audited). It separates different access indications with commas. The output can be used in a **chaudit** command to restore a file to those audit settings (for either user or auditor); if the settings are for the auditor settings, the **-a** option of the command should be used.

In the preceding example listing, both regular files show that the user requests failure auditing for all types of access, and there is no auditor requested auditing.

Extended attributes: The extended attributes are indicated by 'a', 'p', 's' and when on, and '-' when off. These abbreviations stand for APF authorization, Program control, Sharing of the address space setting honored (_BPX_SHAREAS), and Library sharing.

The $EXTATTR format lists the extended attributes by enumerating them, e.g., +ap, -sl (APF authorized, program controlled, does not honor _BPX_SHAREAS and does not use Library sharing). The output can be used in an **extattr** command to restore a file to those extended attributes.

Flag formats: Using available formats for flag field input and ouput: For your convenience this section includes some overviews of the varying flag formats. In addition the concept of *input* and *output* formats is explained here.

When a flag field is read by the program, its value is translated to one of the logical values **true**, **false**, **missing** or **in error**. This translation generally varies with the (database) field; an internal knowledge base takes care of this. As a user you only need to specify how each logical value is displayed by specifying the desired output format.

The following table lists how the various output formats print these logical values.

Table 297. Flag output formats

Output format	TRUE	FALSE	MISSING	ERROR (or value 3)
BLANK$HDR	blank	header	blank	= FALSE
BLANK$NO	blank	"No"	blank	= FALSE
BLANK$STR	blank	string	blank	= FALSE
FLAG	"YES"	blank	blank	"???"
FLAG2NICE	"Yes"	"No"	blank	"?"
HDR$BLANK	header	blank	blank	= FALSE
OPERUND	"YES"	"NO"	blank	"?"
STR$BLANK	string	blank	blank	= FALSE
YESNO	"Yes"	"No"	blank	= FALSE
$CASE	"ASIS"	"UPPER"	blank	= FALSE
$DOM	"NORMAL"	"ALL"	blank	"NONE"
$LOGCMDR	"SYSTEM"	"NO"	blank	= FALSE
$NO	blank	"no"	blank	= FALSE
$XRFSOFS	"FORCE"	"NOFORCE"	blank	= FALSE
$YESNO	"YES"	"NO"	blank	= FALSE

Occasionally you might want to display a flag field that the program does not recognize as such. For example, an SMF_FIELD that you defined. When that happens the program uses an input format (translation of input values to logical values) depending on the specified output format. (At this time it is not supported to change the input format independently of the output format).

The following table lists what input values are interpreted as what logical values in this case.

Table 298. Logical values as translated from input values if the input is not a flag field, depending on the effective output format

Output format	TRUE	FALSE	MISSING	ERROR (or value 3)
BLANK$HDR	first byte x'80'	first byte not x'80	input length 0	-
BLANK$NO	first byte x'80' or x'01'	first byte not (x'80 or x'01')	input length 0	-
BLANK$STR	first byte x'80'	first byte not x'80'	input length 0	-
FLAG	first byte x'80' or x'01'	first byte x'00' or x'40'	input length 0, or first byte x'FF'	first byte anything else
FLAG2NICE	first byte x'80'	first byte x'40'	input length 0, or first byte x'00'	first byte anything else
HDR$BLANK	first byte x'80'	first byte not x'80	input length 0	-

Table 298. Logical values as translated from input values if the input is not a flag field, depending on the effective output format (continued)

Output format	TRUE	FALSE	MISSING	ERROR (or value 3)
OPERUND	first byte x'80'	first byte x'40'	input length 0, or first byte x'00' or x'10'	first byte anything else
STR$BLANK	first byte x'80'	first byte not x'80'	input length 0	-
YESNO	first byte x'80'	first byte not x'80'	input length 0	-
$CASE	first byte x'80'	first byte not x'80'	input length 0	-
$DOM	first byte x'80'	first byte x'40'	input length 0, or first byte anything else	first byte x'20'
$LOGCMDR	first byte x'80'	first byte not x'80'	input length 0	-
$NO	first byte x'80' or x'01'	first byte not (x'80' or x'01')	input length 0	-
$XRFSOFS	first byte x'80'	first byte not x'80'	input length 0	-
$YESNO	first byte x'80' or x'01'	first byte not (x'80' or x'01')	input length 0	-

Note that x'80' is always seen as **true**, x'40' is always seen as **false**, and a field that is not present is always **missing**, so if this is appropriate, there is nothing to worry about. Further note that FLAG sees x'FF' as an 'undefined' value (as is usual in e.g. the RACF database).

Date output formats: Formatting date field output for different locales and standards: zSecure provides an extensive set of DATE format types to output the date information in displays and reports. These format types include: Julian, US, and European. Dates can also be output in TOD (Time-of-Day) format. Each format type also provides different length and display options. For examples, see Figure 514 on page 829

The following figure lists the various DATE formats. Three example dates are used.

length	date	usdate	juldate	$date	eudate
12	1 Mar 2002	03/01/02	2002/060	2002-03-01	01-03-2002
11	1 Mar 2002	03/01/02	2002/060	2002-03-01	01-03-2002
10	01Mar2002	03/01/02	2002/060	2002-03-01	01-03-2002
9	01Mar2002	03/01/02	2002/060	2002-03-0	01-03-02

Figure 515. TOD Date Format example

COMPARE processing output formats: Formatting COMPARE_CHANGES results: Use the following output formats for reporting compare processing results from the COMPARE_CHANGES option. (See "Defining variables for comparison results (COMPAREOPT)" on page 754.)

CMPCHG

This format is a flat condensed output format intended for a value defined as COMPARE_CHANGES. This format is defined as *field*(*value -> value*).

The value between parenthesis is either a value pair with an > symbol in between, or if the field is a repeated field, the values are enclosed between curly brackets: *field*({*value -> value*}). The curly brackets are included if a repeat group has more than one different value. If a value is missing, it is absent in this display format as shown in the following example.

```
CGGRPNM({>{H})
```

The output format CMPCHG can be combined with the HORIZONTAL modifier. The horizontal modifier is applied after the CMPCHG format. The following examples show examples of output with and without the modifier.

Without the horizontal modifier:

```
DFLTGRP(A->C)
CGGRPNM({A,B}->{C,E,F})
```

With the horizontal modifier:

```
DFLTGRP(A->C) CGGRPNM({A,B}->{G,E,F})
```

CMPCHG3

This format for DEFINE COMPARE_CHANGES is like the CMPCHG4 format but without the compliance direction column that indicates whether the change increases or decreases security. The CMPCHG4 format contains the changes detected during the comparison process. This format lists only the fields that have changed, not all comparison fields. The difference found is shown in the form of quadruplets (field name, compliance direction, baseline value, changed value). If the field name is that of a repeated field, the name is repeated as often as necessary to list the differences. In this situation, the baseline value and the changed value shown on any single line need not be related in any way. Instead, the repeat group entries are presented in an alphabetic sequence as shown in the following example.

```
Fieldname       Value-1                         Value-2
CGGRPNM         A                               G
CGGRPNM         B                               E
CGGRPNM                                         F
DFLTGRP         A                               C
```

The COMPARE_CHANGES field is sorted on the Fieldname, which is character format. If the field names are the same, the COMPARE_CHANGES field is sorted on the formatted value of Value-1.

You cannot change the sort order using either the SORT or DESCENDING format modifiers.

CMPCHG4

Default format for the DEFINE COMPARE_CHANGES specification.

This format contains the changes detected during the comparison process. This format lists only the fields that have changed, not all comparison fields. The difference found are shown in the form of quadruplets (field name, compliance direction, baseline value, changed value). If the field name is that of a repeated field, the fieldname is repeated as often as necessary to list the differences. In this situation, the baseline value and the changed value shown on any single line need not be related in any way. Instead the repeat group entries are presented in an alphabetic sequence, as shown in the following example:

```
Fieldname             C Value-1                 Value-2
CGGRPNM                  A                       G
CGGRPNM                  B                       E
CGGRPNM                                          F
DFLTGRP                  A                       F
```

The COMPARE_CHANGES field is sorted on the Fieldname, which is in character format. If the field names are the same, the COMPARE_CHANGES field is sorted on the formatted value of Value-1, and so on.

The sort order cannot be changed by the SORT or DESCENDING format modifiers.

CMPBASV
This overriding output format is intended for a value defined as COMPARE_CHANGES. The output format shows the baseline value of the field. This format can be used as a method to display the third column only of the CMPCHG4 format.

CMPCHGC
This format is much like CMPCHG but adds an extra plus sign (+) or minus sign (–) behind it to indicate whether the change resulted in an increase or decrease in security compliance.

CMPCHGD
This overriding output format is intended for a value defined as COMPARE_CHANGES. It shows the compliance change of the field. Another way to use this output format is as a method to display the second column of the CMPCHG4 format. Possible values for this format include a plus sign (+) or a minus (-) sign.

CMPCHGV
This overriding output format is intended for a value defined as COMPARE_CHANGES. It shows the changed value of the field. Another way to use this output format is as a method to display the fourth column of the CMPCHG4 format.

CMPFLD
This overriding output format is intended for a value defined as COMPARE_CHANGES. Specifying this format results in reporting only field names where a difference was found. The difference between this format and the CMPFLDN format is that the latter repeats the same field name if needed for listing the values in a format similar to CMPCHG4.

CMPFLDC
This overriding output format is intended for a value defined as COMPARE_CHANGES. It results in reporting the field names where a difference was found. This format is like the CMPFLD format. However, it adds an optional compliance direction (+/-) after the reported field names to indicate whether the change resulted in an increase or decrease in security.

CMPFLDN
This overriding output format is intended for a value defined as COMPARE_CHANGES. It shows the name of the changed fields. Another way to use this output format is as a method to display the first column of the CMPCHG4 format.

Using the COMPARE_CHANGES formats: When using the four overriding formats CMPCHGV, CMPBASV, CMPCHGD, CMPFLDN, the individual rows reported correspond to each other by default. In the following example, the specification results shows information like that shown by the specification COMP_CHANGES(CMPCHG4), with smaller columns.

```
COMP_CHANGES(CMPFLDN,8)
COMP_CHANGES(CMPCHG,1)
COMP_CHANGES(CMPBASV,8))
COMP_CHANGES(CMPCHGV,8)
```

The output values are pieces of a coordinated group, just like in format CMPCHG4.

Compare the resulting output shown in the following example output to the output resulting for the CMPCHG4 format shown in the preceding example.

```
Fieldname                C Value-1                Value-2
CGGRPNM                    A                      G
CGGRPNM                    B                       E
CGGRPNM                                            F
DFLTGRP                    A                       F
```

The COMPARE_CHANGES field supports an overriding width. In the absence of any overriding format specification, the default width of the field is 80 characters, split over the three parts as 16/30/30. If an overriding width is specified, the widths of the individual columns are proportionally reduced or increased (and rounded appropriately). This is intended to allow an easy specification of COMP_CHANGES in a narrower format, while still providing useful information. If individual column width tailoring is required, or individual column selections are required, one of the CMP* overriding formats described above should be used.

An individual COMPARE_CHANGES column created by overriding format CMP* can have an overriding width. This is applied to the total column width in the report. To display the output horizontally, use the HORIZONTAL(length) output modifier. The overriding length field applies to an individual entry. The example shows the format specification and results:

```
/ COMP_CHANGES(CMPFLDN,80,HOR(8),PREFIX),
/ COMP_CHANGES(CMPBASV,80,HOR(8),PREFIX),
/ COMP_CHANGES(CMPCHGV,80,HOR(8),PREFIX)
```

```
Fieldname    DFLTGRP  CGGRPNM  CGGRPNM  CGGRPNM
Value-1      A        A        B
Value-2      C        G        E        F
```

In this example, the data shows the following:

- The value for DFLTGRP changed from A to the C.
- In the list of connect groups, the user was removed from the groups A and B and added to groups G, E, and F.

Using the LIST command

The following examples show how to use the format and output modifier parameters for the LIST command.

"Generating a group tree report" on page 834
"Generating separate lines using the newline operators" on page 835

Listing profiles using the profile key

One of the simplest requests is to list the class and name of selected profiles:

```
list class key
```

Changing the output length of a field

If you know the profile type you selected (for example CLASS=USER), you might want to modify the output length of the KEY field to 8 in order to get a concise listing of the users in your database:

```
select class=user
sortlist key(8) pgmrname instdata
```

By using SORTLIST instead of LIST, the profiles are sorted on the field values (in the order of the field names). This results in this example in a report sorted by RACF user ID.

Changing the display format

You can change the display to show data in different formats and field lengths. For example, if the first 3 bytes of the installation data contains bit flags, the default text format results in non-displayable characters that might disturb the printer. In this case, you can display the bit flags in hex. You might also want to specify the maximum length to be displayed. In this example, the correct field length is 6 bytes as shown in this LIST statement.

```
list key(8) instdata(6,hex)
```

Changing a column header

The column header can be changed by including a quoted string in the output name modifier list:

```
sortlist key(8) instdata('Personnel number')
```

The column header can be combined with length and format modifiers in any order. For instance, to add an output display length:

```
sortlist key(8) instdata(16,'Personnel number')
```

Listing the standard access list

To list the standard access list of resource profiles as well as the owner field and universal access, one might specify:

```
list class key owner userid useracs uacc
```

Displaying the access list using the ACL keyword

To display a combined standard access list and conditional access list, use the ACL keyword:

```
newlist
  select class=dataset, key=sys1.**
  sortlist class key owner acl
```

Including user information in the access list

To include the programmer data in the access list, one can use an indirect reference to the USER profile:

```
newlist
  select class=dataset, mask=sys1.**
  sortlist key owner acl acl:pgmrname
```

The users' installation data could have been included using ACL:INSTDATA.

Displaying the resolved access list

To show **all** user IDs that have access to a resource via the ACL, and calculate the actual access level of each user, use the ACL keyword with the RESOLVE format:

```
newlist
  select class=dataset, key=sys1.**
  sortlist class key owner acl(resolve)
```

As an alternative, the EXPLODE output modifier could have been used to display all the ways the users have been granted access. Using the EFFECTIVE output modifier would have summarized the actual access just like RESOLVE, but also included implicit access due to e.g. group operations.

Generating profile commands

To generate a command for each profile selected, you can use the string parameter of the list command. You can redirect the output to any file, for instance to CKRCMD. For instance, if you want to give every TSO user a permit to a specific account number:

```
newlist ddname=ckrcmd nopage
   select class=user, tso  /* all profiles with TSO segment */
   list 'PERMIT TSOACCT CLASS(ACCTNUM) ID(' | key(8) | ')'
```

The NEWLIST NOPAGE parameter can be used to suppress page headers when generating commands.

Generating repeat group commands

To generate a command for each repeat group entry of a selected profile, you can use the string parameter of the list command in combination with the RETAIN keyword of PRINT/NEWLIST. You can redirect the output to any file, also to CKRCMD. For instance, if you want to copy the class authorizations of a user to a different user:

```
newlist ddname=ckrcmd retain nopage
   select class=user, profile=USER1
   list 'ALU USER2 CLAUTH(' clname ')'
```

The preceding example would generate one RACF command for every authorized class. As an alternative, you could use the HORIZONTAL output modifier to generate just one command for each user, as demonstrated in the following example:

```
newlist ddname=ckrcmd nopage
   select class=user, profile=USER1
   list 'ALU USER2 CLAUTH(' clname(horizontal) ')'
```

The NEWLIST NOPAGE parameter can be used to suppress page headers when generating commands.

Generating a group tree report

The following example generates a simple group tree report; for each group, the group name (KEY) and installation data are displayed. The TREELINE field is sorts the groups in the proper order and the INDENT output modifier displays each group name at the proper offset. The DEPTH field must be present, since it is used by INDENT. Because a group name can be up to eight characters long, this example can handle groups up to a depth of 32 characters.

```
newlist type=racf
   select class=group
   sortlist treeline(nondisplay) key(40,indent(depth)) depth(nondisplay),
            instdata
```

Generating separate lines using the newline operators

To generate separate lines without changing the order of the values of repeated fields, you can use the soft newline operator '/n'. You can see this in the following queries.

When no newline operators are specified, repeated fields are shown as follows:

```
newlist
sortlist fieldA fieldB fieldC fieldD
```

Results in:

```
valueA1 valueB1 valueC1 valueD1
valueA2 valueB2         valueD2
valueA3
```

A normal newline operator '/' will first print the repeated fields before it with all their values, and then the fields after it:

```
newlist
sortlist fieldA fieldB / fieldC fieldD
```

Results in:

```
valueA1 valueB1
valueA2 valueB2
valueA3
valueC1 valueD1
        valueD2
```

A soft newline operator will keep the order of the values intact:

```
newlist
sortlist fieldA fieldB /n fieldC fieldD
```

Results in:

```
valueA1 valueB1
valueC1 valueD1
valueA2 valueB2
        valueD2
valueA3
```

MARGINS

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

This command sets the margins for reading the SYSIN file. The command can be abbreviated as MARGIN . The command must be followed by two decimal numbers separated by a comma and enclosed in parentheses.

```
MARGINS(nn,mm)
```

The first number gives the starting column for the text to consider (the first column is column number 1). The second number gives the last column to be read. Both numbers must be in the range 1 to 255, and the first number cannot be greater than the second number.

The default is dependent on the input LRECL and RECFM. For an LRECL=80 RECFM=F file (the MVS/JES2 default for inline SYSIN files), the following margins column settings:

```
margins(1,72)
```

This default ignores line numbers in column 73 to 80.

Margins commands in included files/members apply to the included file/member itself. You can also use the MARGINS parameter on the INCLUDE command to set margins for included members and files. Margins statements in a JCL parm set the default margins for reading the SYSIN file.

MENU

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•	•	•	•	•	•	•

This command exists only for backward compatibility.

This command causes interactive operation under ISPF. The parameters of the MENU command can be used to select a 'selection panel' for display. You only need to use this command if you are customizing the ISPF interface. Specifying a non-existing panel name causes the application to be terminated.

CFS= *panel*
Menu panel name to be displayed after reading system configuration information from all CKFREEZE files.

MERGE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•			

Use the MERGE command to perform a RACF database merge. The command starts a block with a special syntax. This block is ended with an ENDMERGE command.

Between the MERGE and ENDMERGE commands (inside merge scope) normal CARLa syntax does not apply.

Note: You cannot MERGE databases accessed by the zSecure network. However, you can MERGE remote UNLOAD files.

The MERGE command only supports the following commands.

DEFINE
For example used to define variables for use in SELECT and EXCLUDE commands or later NEWLIST reports.

INCLUDE/IMBED
To include another file containing commands.

MERGERULE
Changes the way the merge decisions are made as described in "MERGERULE" on page 838. This command can only be used within a MERGE/ENDMERGE block. The MERGERULE command

SELECT/EXCLUDE
To select profiles from the SOURCE database. Based on the selected profiles of the SOURCE database, and optional MERGERULE commands, the merge process automatically selects relevant profiles from the CURRENT database.

When specifying `SELECT` and `EXCLUDE` selection criteria for the merge process, only use fields from the `BASE` segment. If the `BASE` segment is selected, the entire profile is merged. If the `BASE` segment is not selected, the entire profile is skipped, even if all non-`BASE` segments are selected.

MERGELIST

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

Use the `MERGELIST` command to merge output of a number of NEWLIST commands. Its primary purpose is in creating ISPF displays that have different detail displays accessible from a common overview display. Another application is combining information from more than one profile segment into a multi-line report for each profile.

MERGELIST causes all NEWLISTs up to an ENDMERGE statement to be combined in a single display. The records are merged according to SORTLIST sort order. The sort is done column by column from left to right, irrespective of the field name displayed in the column. LIST, SUMMARY, and DSUMMARY are not supported in a MERGELIST, only SORTLIST/DISPLAY.

A maximum of 255 NEWLISTs are supported between a MERGELIST/ENDMERGE pair. If more NEWLISTs are required, consider dividing them over two or more MERGELIST/ENDMERGE pairs. There is only one MERGELIST level; that is, MERGELISTs cannot be nested.

Most *print parameters* (such as output DDname) are taken from the first NEWLIST statement; the parameters from the next NEWLISTs are ignored. The exceptions to this are the ISPF second-level (repeat group / detail) parameters, (that is, TITLE, SUBTITLE, DETAILHELPPANEL) and modifier details; these are taken from the actual NEWLIST that generated the output.

When the first NEWLIST is suppressed, the entire MERGELIST is suppressed (except when there is no collation because LIST has been used). Reasons for suppression can be a mismatching SEGMENT=*segment*, ESM=*esm*, LICENSE=*productcode*, UNRESTRICTED, RDS, or NONRDS specification. For example, when you want to mix RACF-specific and ACF2-specific report output into one MERGELIST, you might want to include a dummy `NEWLIST TYPE=SYSTEM OUTLIM=0` at the start so that there is no ESM= effective on the MERGELIST level.

Notes:

1. SEGMENT=BASE on the first NEWLIST is considered safe.

2. Suppression of TYPE=RACF newlists can also occur because of SUPPRESS RACF or the absence of a RACF data source.

When running in a "real-time" context, (for example, as part of zSecure Alert), output is processed in intervals. If the input for a particular NEWLIST type has been exhausted, the NEWLISTs of that type are suppressed.

Whenever a secondary NEWLIST is suppressed only because the first NEWLIST is suppressed, a warning message is issued (CKR2335-CKR2338). The return code for messages CKR2335, CKR2336, and CKR2337 can be adjusted through OPTION MSGRC=.

NAME
Name for the mergelist. When FILEFORMAT=XML is specified, this name is required; it used as the XML element name for all records output by the member NEWLISTs (for example those between MERGELIST and ENDMERGE). All fields that form a common prefix for each member NEWLISTLIST/SORTLIST/SUMMARY statements will be output as elements for this MERGELIST XML element. If a member NEWLIST contains additional fields, a subelement named with NEWLIST NAME= will be present, too. For an XML example, see "FILEFORMAT" on page 781.

DD
ddname
FILE
F Output file to use as a default for the newlists between MERGELIST and ENDMERGE. When you have also used a FILEOPTION statement for this file you do not need to specify DD= and the desired print parameters on each NEWLIST between MERGELIST and ENDMERGE.

Example

The following example shows a simple MERGELIST/ENDMERGE combination. The external selection selects all profiles with key DEMO*. Inside the MERGELIST/ENDMERGE, a further selection is made into user and group profiles; the output is dependent on the profile type.

```
select mask=demo*
mergelist
 newlist type=racf
  select class=user
  sortlist key(8) '(User) ' owner pgmrname instdata
 newlist type=racf
  select class=group
  sortlist key(8) '(Group)' owner supgroup instdata
endmerge
```

MERGERULE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•			

The MERGERULE command can be used to alter the way that the merge process works. It can be used to set global merge options, which are used as a default, or to set local options, which apply to a specific user or group and related profiles.

The following diagram describes the MERGERULE syntax:

```
MERGERULE        DEFAULT / SOURCEID= / SOURCECLASS=
                 options
MERGERULE        DEFAULT
                 [ AUTHORITY= ]
                 [ CONNECT= ]
                 [ CKGRACF=|CNGRACF=]
                 [ DATA= ]

MERGERULE        SOURCEID=
                 [ AUTHORITY= ]
                 [ CONNECT= ]
                 [ DATA= ]
                 [ OWNER= ]
                 [ RENAME= ]
                 [ SUPGROUP= ]

MERGERULE        SOURCECLASS=
                 [ AUTHORITY= ]
                 [ DATA= ]

AUTHORITY=       LOW
                 HIGH
                 MERGESOURCE, SOURCE
                 CURRENT
                 FLAG

CONNECT=         IFUSER
                 IFGROUP
                 IFBOTH
                 IFANY
                 NONE

DATA=            MERGESOURCE, SOURCE
                 CURRENT
                 FLAG

CKGRACF=|CNGRACF YES
                 NO
```

The MERGERULE DEFAULT statement applies to the global merge options, which have lower priority than a local (user or group-specific) MERGERULE SOURCEID command. It can be used to specify the default authority used, the default connect settings used, and the use of CKGRACF in the command output file.

The MERGERULE SOURCEID statement applies to one or more users or groups and related profiles (based on high-level qualifier), and has higher priority than the default values. It can be used to set the authority used, the connect setting, to apply a specific owner or superior group, and to rename the id during the merge process.

The MERGERULE SOURCECLASS statement applies to one or more general resource classes, and has higher priority than the default values. It can be used to set the authority and/or other data settings used during the merge process. Its syntax rules and limitations are the same as those of the MERGERULE SOURCEID statement.

All options can be specified using parentheses and/or an equal sign. (A list of ids must be enclosed in parentheses). For example, the following commands are valid:

```
mergerule sourceid(sys1) authority=flag
mergerule sourceid=ibmuser authority(mergesource)
mergerule sourceid=(ibmuser,cicsuser) owner=sys1
mergerule sourceid(ibmuser,sys1) connect(ifany)
```

Abbreviations are not supported. You can specify parameters for the same id on multiple MERGERULE commands, as the previous example shows. You cannot specify the same parameter multiple times for the same ID.

The MERGERULE keywords are:

AUTHORITY
The AUTHORITY keyword is used to specify the policy used for the id, in those cases where a security-related choice between the source and the current system must be made.

HIGH
Grants the highest access/authority. May cause security problems because of excessive access, so use with care.

LOW
Grants the lowest access/authority. May cause existing access to be removed.

SOURCE
Copy the access/authority from the MERGESOURCE system.

CURRENT
Copy the access/authority from the CURRENT system.

FLAG
Try to fall back on a default policy (if this is a local policy), or on a built-in default. If no decision could be made, issue an error message.

CKGRACF
The CKGRACF keyword determines whether CKGRACF commands are to be generated to set fields that cannot be set by RACF commands.

YES
Generate CKGRACF commands.

NO
Do not generate CKGRACF commands.

CONNECT
The CONNECT option determines which user group connections are to be copied; as decision criteria, the selected state of the user and the group are used. The connect attributes copied depend on the AUTHORITY setting.

NONE
Do not copy any user group connection.

IFBOTH
Only copy a connect if both source user and source group are selected.

IFANY
Copy a connect if either source user or source group, or both, is selected. If only one side is selected, the other side must already exist on the current system; otherwise, the connect is skipped.

IFUSER
Copy a connect if the source user is selected. If the group is not selected, it must already exist on the current system; otherwise, the connect is skipped.

IFGROUP
Copy a connect if the source group is selected. If the user is not selected, it must already exist on the current system; otherwise, the connect is skipped.

DATA
The DATA keyword is used to specify the policy used when a non-security-related choice between the source and the current system must be made.

SOURCE
Copy the field from the MERGESOURCE system.

CURRENT
Copy the field from the CURRENT system.

FLAG
Try to fall back on a default policy (if this is a local policy), or on a built-in default. If no decision could be made, issue an error message.

OWNER
Set a new owner for the specified user or group id.

RENAME
The RENAME parameter renames a SOURCE id to the specified new CURRENT id. This can be used to change the name of a user or group during the recreate process. Related profiles, as based on the high-level qualifier, are also renamed.

SUPGROUP
Set a new superior group for the specified group id.

Effect of keywords

The effect of the parameters is the following:

- A MERGERULE SOURCEID=xx, SUPGRP, OWNER, or NEWNAME command has the highest priority. These override any other command, and built-in defaults.

  If one of these keywords is specified for one or more ids, it is either applied or leads to a fatal error.
- The CONNECT options determine which user group connections to copy. A MERGERULE SOURCEID=xx (local) has higher priority than a MERGERULE DEFAULT command (global).

  If the CONNECTS keyword is specified for an id, its effect is dependent on the selected status and type of the target: it applies only if the target is selected. If both user and group have a command that could apply, and both are selected, the command for the user is used.
- The AUTHORITY and DATA options are used when deciding on security attributes such as (group)special. A MERGERULE SOURCEID=xx option overrides a MERGERULE DEFAULT option. The same holds for a MERGERULE SOURCECLASS=xx option.

  If either keyword is used, it applies only to those cases where a conflict needs to be resolved. There is no way to specify security attributes or data attributes if there is no conflict, for example source-only, or source equals current.
- IBM Security zSecure Admin built-in (non-command determined) alternatives are used as a last resort, for example if no local or default option could be used to resolve the problem.

MOVE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
		•	•			

The MOVE command generates RACF commands for moving a user to a new group and for removing users, groups, and permits or notify fields from the data set profiles of the old group. In the presence of one or more CKFREEZE files, the move operation also generates commands to delete data sets covered by removed profiles, data sets not covered by any profile, and catalog aliases having the sourceid as HLQ (if the command is intended to move the user to a *holding group* before deleting the user.

Note: The MOVE command is only supported if you have IBM Security zSecure Admin installed and enabled.

The MOVE command does not issue any commands by itself. The generated RACF commands are written to the CKRCMD file. [6] To complete the MOVE operations, verify and confirm the commands in the CKRCMD file and then run them.

The MOVE command syntax is similar to the syntax for the COPY and REMOVE commands. The MOVE command is mutually exclusive with VERIFY STC.

When the MOVE command runs, the resulting messages are similar to those generated by the COPY and REMOVE commands except that these messages include the *Move* term instead of *Copy* , *Replace*, or *Delete*, except the non-RACF commands, which generate messages that use the term *Resource deletion:*.

The keys and members of RACFVARS profiles are by default interpreted as users and groups when they match a valid user or group id, and they are managed accordingly, unless you use the SUPPRESS MANAGERACFVARS command. A discrete first qualifier in the key of a STARTED profile is only interpreted as a user ID when it matches the specification in the STUSER field in the STDATA segment.

The resource deletion commands generated as a result of the MOVE command can include ALLOCATE and FREE commands to delete uncataloged data sets. These commands are acceptable to TSO but not directly to IDCAMS. You can exclude these commands by specifying SUPPRESS DELETEUNCATALOGED, which will list the VTOC entries concerned in the SYSPRINT (as kept).

For a comprehensive description of the resource Delete functions, see "REMOVE" on page 870 and "SUPPRESS" on page 932.

For more information, see the following sections:

- "MOVE command parameter descriptions"
- "Using the MOVE command" on page 845

MOVE command parameter descriptions

The MOVE command has two types of parameters: user and group processing parameters and parameters that are modifiers for the processing parameters.

User and group processing parameters

The following user and group processing parameters for the MOVE command are mutually exclusive on a single MOVE command. If you want to use more than one

6. Commands in the CKRCMD file can also be generated as the result of a MOVE, REMOVE, or VERIFY command or a PRINT DD=CKRCMD command.

of these parameters, specify one MOVE command for each parameter. These parameters are also mutually exclusive with the VERIFY PERMIT command.

PERMIT= *id*

To prepare for moving the user ID or group, generate commands to remove references to the specified *id* from the following resources: access lists, OWNER fields, NOTIFY fields, RESOWNER fields, STUSER and STGROUP fields, NODES members, certain APPLDATA fields, and functional positions in profile keys and members of the classes:

- DATASET
- DLFCLASS
- INFOMAN
- CICS: TCICSTRN, GCICSTRN, DCICSDCT, ECICSDCT, FCICSFCT, HCICSFCT, ACICSPCT, BCICSPCT, JCICJCT, KCICSJCT, MCICSPPT, NCICSPPT, PCICSPSB, QCICSPSB, SCICSTST, UCICSTST, CCICSCMD, VCICSCMD
- VM: VMMDISK, VMRDR, VMBATCH, VMCONECT, VMEVENT, VMXEVENT, VMCMD
- SURROGAT
- PROPCNTL
- PTKTDATA
- LFSCLASS
- JESJOBS, JESSPOOL
- NODES
- STARTED, FACILITY
- TMEADMIN

You can limit the scope of the PERMIT using the FROMGROUP, TOGROUP, , and ALLPERMIT parameters as well as the SUPPRESS DELDSD command.

During the reference removal process, the following processing applies:

- If you specify the FROMGROUP parameter, the program only removes references in data set profiles of the indicated groups. It does not remove any references in general resource profiles or other user or group profiles.
- If you specify TOGROUP, the program removes all references except from the indicated group, the subject user, and general resource profiles.
- Deletes references in STUSER, STGROUP, and RESOWNER fields. To change profile ownership, certain APPLDATA and NOTIFY fields are deleted as appropriate.
- Creates commands to delete access list entries.
- Removes NOTIFY fields unless you specify the NEWNOTIFY parameter indicating which user should replace the one to be removed.
- Profile ownership is changed based on the following criteria:
  - For group data set profiles, it change to the first qualifier, as changed by ICHCNX00.
  - For connect profiles, ownership changes to the owner set by the command DEFAULT OWNER= or to the system default SYS1 if this command is not present.
- For other profiles, NOTIFY fields are removed unless the NEWNOTIFY parameter is used to indicate which user should replace the one to be removed.

NOTIFY= *id*

NOTIFY performs a subset of MOVE PERMIT= processing that is limited to NOTIFY fields.

USER= *idlist*

The USER parameter removes one or more users from the groups that are specified by the FROMGROUP parameter, and also removes all references to the user in the data set profiles of those groups. The USER parameter specifies all processing for `MOVE PERMIT=` and also generates RACF commands to remove the user from its connect groups and to modify the user's default group as needed.

The value specified for the *idlist* can be a single user name or a list of user names enclosed in parentheses and separated by commas.

Modifier parameters for user and group processing

The following modifier parameters can be used to adjust the processing performed by the PERMIT, NOTIFY, and USER command options.

FROMGROUP= *idlist*

This parameter limits the scope of the removal to the groups specified in *idlist*, which can be a single group name, or a list of group names enclosed in parentheses and separated by commas. This limitation of scope also extends to the data set profiles of the group: removal of access lists, owner fields, and so on is only done for profiles belonging to one of the groups specified in the list, which are identified either by their first qualifier or the qualifier returned by ICHCNX00.

TOGROUP= *idlist*

This parameter specifies a group or list of groups (*idlist* to which the user is to be connected. These connections replace the connections to the groups the users is currently connected to. If the FROMGROUP parameter is specified along with the TOGROUP parameter, the connections replace the connections to the groups specified by the FROMGROUP parameter. If a list of groups is specified, the list must be enclosed in parentheses with each group separated by a comma.

The TOGROUP option also reduces the scope of removal to exclude the personal data set profiles of the user, the group data set profiles of groups in the TOGROUP list, and all general resource profiles. If the ALLPERMITS parameter is specified along with the TOGROUP opton, even the user's profiles and references in general resource profiles are removed. The specified group can be a current connect group; in this case no connect command is generated.

The TOGROUP parameter is required when you specify MOVE USER or MOVE PERMIT commands.

ALLPERMITS

This parameter is valid only if it is specified after the TOGROUP parameter. ALLPERMITS causes references in all profiles to be removed, except by profiles of the group(s) specified on TOGROUP. This includes the user's profiles and general resource profiles that would be omitted by TOGROUP. The intended use of the ALLPERMITS parameter is to move a user to a *holding group* before deleting it. Therefore, it implies the generation of IDCAMS commands to delete the data sets and catalog aliases for the user as well, unless you specified `SUPPRESS DELETEDATASETS` for the run. Also, see the REVOKE parameter.

NEWNOTIFY= *id*

This parameter indicates a replacement user ID to be used for NOTIFY fields processed by the user/group removal commands.

REVOKE

This parameter can be used to revoke the user ID as well as performing the other actions on the MOVE command. The primary use of the REVOKE

parameter is to remove a user ID and move it to a holding group prior to deletion in a command such as `MOVE USER=`*id* `TOGROUP= REVOKE`*hold*.

Note: All parameters can also be specified as parm(value) in addition to `parm=value`.

Using the MOVE command

The parameters and other options you use with the MOVE command depend on the context of the user ID you want to move and also where you want to move it. The following sections provide examples of using MOVE commands in different scenarios.

- "Moving a user to staging group"
- "Moving a user to another department"
- "Transferring NOTIFY to a different user"

Moving a user to staging group

The following example generates commands to remove all references to a user ID JONES from the database and move the user ID to a staging group.

```
move user=jones togroup=holddel allpermits revoke
```

When this command is issued, RACF commands are generated for the following task and written to the CKRCMD file where you can verify and confirm them before submitting them:

- Remove all profiles for the user ID JONES.
- If the necessary CKFREEZE files are supplied, remove all the data sets covered by the profiles as well as any data sets without any covering profile and catalog aliases having JONES as their HLQ (tape data sets only if they are cataloged and migrated), a
- Move the user ID to a holding group temporarily so it can be deleted later, for example after it has been removed from non-RACF user definitions.

The default group of the user is changed as necessary.

For details on the parameters used in the command, see "MOVE command parameter descriptions" on page 842.

Moving a user to another department

The following example generates commands to move a user to a new department.

```
move user=jones fromgroup=dept1 togroup=dept2
```

When this command is run, it removes all authorities of the user *jones* on data set profiles of the group, *dept1* and connects the user to the new group. All authorities on general resource profiles and personal profiles for *jones* remain intact.

For details on the parameters used in the command, see "MOVE command parameter descriptions" on page 842.

Transferring NOTIFY to a different user

The following example shows how to generate commands to transfer all NOTIFYs on the data set profiles of a group to another user. For example, you might use this command to transfer NOTIFY responsibilities when a user is on temporary leave.

```
move notify=jones fromgroup=dept1 newnotify=parker
```

In this example, the NOTIFY responsibilities for the user ID *jones* in *dept1* are transferred to the user ID *parker*.

For details on the parameters used in the command, see "MOVE command parameter descriptions" on page 842.

NEWLIST

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

Use this command to generate more than one report, ISPF table, or unload file in one CKRCARLA program run. You use this command in combination with the following CARLa commands: LIST, DISPLAY, SORTLIST, SUMMARY, or UNLOAD.

For more information, see the following topics:

- "Selecting, formatting, and sending report data"
- "Sorting report data"
- "NEWLIST syntax rules" on page 847
- "NEWLIST parameter descriptions" on page 847
- "Overview of NEWLIST types" on page 850
- "Example NEWLIST commands" on page 855

Selecting, formatting, and sending report data

For reporting, the NEWLIST command marks the beginning of a new report description. You follow a NEWLIST command with the commands that determine what data is included in the report, the report format, and whether it is shown on the screen or printed: OPTION, SELECT, EXCLUDE, LIST, SORTLIST, SUMMARY, DSUMMARY, or UNLOAD. You can specify default settings for report selection, output formats, and output destination by specifying these commands as input before the first NEWLIST command. During processing, these commands are processed first. You can override the default options by specifying a new setting after the NEWLIST command where the setting applies. With each NEWLIST command, the options are reset to the default settings.

Within a NEWLIST block, any print or selection options you specify must be specified *before* the LIST, SORTLIST, DISPLAY, UNLOAD, or SUMMARY command.

You can use the NEWLIST command to direct different selections of LIST or SORTLIST output to a separate output file. See the Option command for an example.

If the selection criteria you specify do not result in any records being selected for the NEWLIST, no output is created even if you have specified a title. As a result, you can create reports or ISPF tables that only show in a pop-up window when one of the NEWLIST selection criteria is matched. See the EMPTYLIST keyword in "OPTION" on page 856 for details.

Sorting report data

When you create reports, you can direct the output for each NEWLIST statement to a separate file or direct all the output to the same file.

- If you direct the NEWLIST output to separate files, use LIST command to create the report. Each file contains the report output for the associated NEWLIST.

- If you direct the output from multiple NEWLIST statements to the same file, use the SORTLIST command on the NEWLIST statements instead of the LIST command. When you use the SORTLIST command, the report data is organized by NEWLIST type.

  If you use the LIST command in this situation, the data is written as it is processed. As a result, the report data from different NEWLIST statements can be mixed together, depending on the sequence of the commands.

NEWLIST syntax rules

The following syntax rules apply to the NEWLIST command.

- You can abbreviate the NEWLIST command to NEW or N.
- Within a MERGELIST and ENDMERGE command pair, you can specify a maximum of 255 NEWLISTs statements.
- Outside of a MERGELIST, you can specify as many NEWLIST commands as you need. There is no limitation.
- The NEWLIST statement accepts almost the same parameters as the OPTION command. For more syntax information, see "OPTION" on page 856. The parameters accepted by are the same as for the OPTION command. For additional examples, see the OPTION, LIST, and SELECT commands.

NEWLIST parameter descriptions

The following parameters apply to the NEWLIST command.

TYPE= *type*
This parameter identifies the type of information to be used as input for the NEWLIST. The default NEWLIST type is TYPE=RACF. In addition to the predefined types, described in "Overview of NEWLIST types" on page 850, all types created with the DEFTYPE TYPE=*type* command are accepted.

CMD
Issue each line of the LIST or SORTLIST output in this NEWLIST as local only, immediate TSO commands instead of as file output, unless the CMDTOFILE option is active. See "CMDTOFILE" on page 857. This type is only supported for RACF commands, the IDCAMS DEFINE command, and DELETE commands. For those APF authorized commands to work, either the program must be run APF authorized, or it must run under TSO (program IKJEFT01 in the batch or interactively). The maximum command length supported is 4096 (because of RRSF).

When you specify this CMD, the command is run immediately on the system that is running zSecure. The command is not subject to SETUP CONFIRM settings, nor issued through the CKRCMD file. This has been designed to be used as part of zSecure Alert (zSecure Audit for RACF running as a subtask in the C2POLICE address space).

COMPAREOPT=*compareopt*
Specifies the name of the COMPAREOPT specification to use with specified NEWLIST. The value specified must match the name specified for a defined COMPAREOPT statement. You can also specify the value DEFAULT to use the default COMPAREOPT specification as long as the default COMPAREOPT statement has been established by use of the FUNCTION=BASE option on an applicable ALLOC statement.

DETAIL
This requests that the fields on the DISPLAY command are by default shown on the detail panel and not on the overview panel. You can override this value with one of the following general output modifiers: NODETAIL BOTH, MORE

or NONDISPL on the field level. Because a DISPLAY command must show output on the overview panel, you must specify at least one override.

ESM= *list*
This parameter can be used limit the scope of this NEWLIST to input complexes that have an External Security Manager of any of the indicated types. The list can be a type or a list of types, where type can be RACF, ACF2, TSS, or NONE. This parameter is ignored for NEWLIST TYPE=DASDVOL, which produces a single cross-complex report.

ISPFTAB= *name*
I=*name*
This sets the name to be used for the NEWLIST on the NEWLIST selection level (only shown when multiple NEWLISTs have resulted in an ISPF display, for those NEWLISTs). The name specified need not be unique in the run, so this parameter can be used to show a single relevant name to select from several alternative NEWLISTs (e.g., because of RDS, NONRDS, LICENSE=*list*, or ESM=*list* criteria). On the other hand, it cannot be used in a LIKELIST=*name* clause. See also NAME=*name*.

LICENSE= *list*
This parameter limits the execution of the query to those products covered by the product codes listed. This makes it possible to have one CARLa input stream that gives tailored output for each product/license, for example a single set of SMF queries for both zSecure Audit for RACF and zSecure Audit for ACF2. The SELECT/LIST statements are not processed if the query does not apply. However, the NEWLIST statement is processed, and can still cause an error on an uninstalled NEWLIST type, for example. To prevent this problem, put the query into a separate member and use the LICENSE= parameter of the IMBED command instead (this will skip parsing the member entirely).

The following table lists the product codes that correspond to IBM Security zSecure products.

Table 299. Product codes

ADMINRACF	zSecure Admin
ALERTRACF	zSecure Alert for RACF
ALERTACF2	zSecure Alert for ACF2
AUDITRACF	zSecure Audit for RACF
AUDITACF2	zSecure Audit for ACF2
AUDITTSS	zSecure Audit for Top Secret
TCIMRACF	Tivoli Compliance Insight Manager Enabler for RACF
TCIMACF2	Tivoli Compliance Insight Manager Enabler for ACF2
TCIMTSS	Tivoli Compliance Insight Manager Enabler for Top Secret
TCIMCICS	Tivoli Compliance Insight Manager Enabler for CICS
TCIMDB2	Tivoli Compliance Insight Manager Enabler for DB2
zsecure_visual_s	zSecure Visual

zSecure Admin and Audit corresponds to (ADMINRACF, AUDITRACF).

NAME= *name*
N=*name*
This assigns an identifier to the NEWLIST, which is required if this NEWLIST is to be referred to by a LIKELIST=*name* clause on a SELECT or EXCLUDE

statement. The name assignment must be unique in the run. The name is also reported in the print summary in SYSPRINT. It is also used for the NEWLIST on the NEWLIST selection level (only shown when multiple NEWLISTs have resulted in an ISPF display, for those NEWLISTs), unless ISPFTAB=*name* was specified to control this separately. This parameter is required when output is directed to an output file with FILEFORMAT=XML.

NODUP
Eliminate duplicate records, for example records with identical contents in the columns used in the NEWLIST. For repeated fields, only the first value in a repeated field is used in the comparison. In the case of a summary, NODUP applies both to the input to the summary (duplicates are eliminated before the summary) as to the detail level (duplicate lines are removed, but they are counted, for instance when summarizing a repeat group field). This option does not apply to LIST output, since that command outputs each line immediately and does not remember previous lines.

Note that duplicate output lines might still be present, because different values can look the same due to formatting or truncation.

PROFLIST= *name*
NOTPROFLIST=*name*
PROFLIST indicates that the selections made by this list should be further filtered to include only information for the profiles selected by the referenced NEWLIST. NOTPROFLIST indicates that the selections made by this list should be further filtered to exclude all information for profiles selected by the referenced NEWLIST. The *name* must have been defined by a prior NEWLIST NAME= statement. This can for instance be used to combine reports on segment information of profiles selected in another NEWLIST based on fields in the base segment. You must be aware that all information as selected by the SELECT and EXCLUDE statements in *this* NEWLIST is stored in-storage, and the filtering through PROFLIST or NOTPROFLIST takes place later. So you should make the SELECT as restrictive as possible, in spite of the fact that the output remains the same whether or not a SELECT is present. In many cases, using SELECT LISTLIKE would be a useful alternative. A NEWLIST can have only one PROFLIST or NOTPROFLIST specification.

RETAIN
This option causes all non-repeat group fields on a SORTLIST or LIST to be repeated for each line that is needed to list the contents of all repeat groups. It can for instance be used to generate a command for each occurrence in a repeat group. It can be overridden locally by means of the output modifier NORETAIN. the keyword has no effect on a DISPLAY, unless it is routed to file (and becomes equivalent to SORTLIST).

SCOPE= *id*
Limit the output of a NEWLIST type containing resource information to information inside the scope of authority of the specified id (which can be a RACF user ID, or a RACF group). The scope check does not take into account system-wide attributesSPECIAL, OPERATIONS, and AUDITOR, but it does take into account group-SPECIAL, group-OPERATIONS and group-AUDITOR. SCOPE is only valid for NEWLIST TYPE=RACF and TYPE=SMF. The scope check applies to the UNLOAD command only for NEWLIST TYPE=SMF.

SEGMENT= *segment*
Suppress the NEWLIST if the segment indicated is not defined in the RACF database templates. Field names in the LIST family of commands are searched first in the indicated segment. This is needed for field PROGRAM in the OMVS segment since PROGRAM is also part of a base segment, having different

properties. This option also changes the meaning of the D action command to generate a command to remove the segment only instead of the complete profile.

SNMP
Requests an SNMP trap to be sent for each record in the NEWLIST. The destination must have been set with SNMPTO= option. If this OPTION parameter has not been specified before the first NEWLIST statement or on the NEWLIST statement, then output defaults to file output as if DD=C2RSNMP had been specified. SNMP traps are requested with a line length of 1066: 32 for a variable name, 1 blank, and a maximum value length of 1023. SNMP is mutually exclusive with email and WTO. SNMP is supported only on z/OS.

SYSLOG
Requests a syslog trap to be sent for each record in the NEWLIST. The destination for the output must have been set using the SYSLOGTO= keyword for the OPTION command. If this parameter has not been specified before the first NEWLIST statement and is not present on the first NEWLIST statement, then output defaults to file output as if DD=C2RSYSLG had been specified. Syslog traps are requested with line length 2048 and UTF-8 encoding. SYSLOG is mutually exclusive with the SNMP, email, and WTO parameters. SYSLOG is supported only on z/OS.

WTO
Issues a multi-line Writer to Operator (WTO) message for each record in the NEWLIST. The WTOs are issued with routing code 9 (security) descriptor code 12 (informational). The number of lines is limited to 10 and the maximum line length is 70. If more than 10 lines are generated, message CKR1421 is output. The extra lines are not issued, but they do appear in the SYSPRINT. Make sure the NEWLIST output record starts with a regular message identifier. WTO is mutually exclusive with the SYSLOG, email and SNMP parameters.

The WTO message format is affected by the APF status of the program. When the program is operating in APF authorized mode–that is, started through CKRCARLX or C2POLICE programs–the program adds a '+' in front of the message ID to prevent spoofing messages that trigger unwarranted Automated Operations responses. The '+' is not added to message IDs that start with C2P1 through C2P8, inclusive. For information about the APF authorization, see Chapter 11, “Calling zSecure,” on page 689.

Overview of NEWLIST types

The NEWLIST types that can be used depend on the product. Table 300 lists all NEWLIST types and the products which provide support for each type. See the Usage guides for additional information.

Table 300. Support for NEWLIST types by product

Newlist type	Description	ADMIN	Audit for RACF	Audit for ACF2	Audit for TSS
ACCESS	Access Monitor records	•			
ACF2_CLASMAP	ACF2 CLASMAP (map SAF class to resource type)			•	
ACF2_FDE	ACF2 Field Definition Entries			•	
ACF2_INFO	ACF2 Infostorage entries			•	

Table 300. Support for NEWLIST types by product (continued)

Example NEWLIST commands

- "Selecting data outside and within the scope of a NEWLIST command"
- "Selecting data as placeholder using a NEWLIST"

Selecting data outside and within the scope of a NEWLIST command

This example shows a selection applying to all reports, and two NEWLISTs with a further subselection. This selection only works for NEWLIST TYPE=RACF, since a SELECT outside a NEWLIST scope *always* applies to NEWLIST TYPE=RACF processing. Refer to the next example for an alternative that is valid for all NEWLIST types. In addition, a title is generated common to all reports, and a subtitle that is different for each report.

```
print title='ABC Computer Services Inc, phone 234-17829'
select class=user
newlist subtitle='Users with system-wide SPECIAL attribute'
   select special
   sortlist key(8) pgmrname dfltgrp instdata
newlist subtitle='Users with system-wide OPERATIONS attribute'
   select operations
   sortlist key(8) pgmrname dfltgrp instdata
```

Selecting data as placeholder using a NEWLIST

This example shows a selection applying to one report that acts as a placeholder and does not generate any output, and two further NEWLISTs with a further selection. You can use this selection method with all NEWLIST types.

```
newlist type=racf outlim=0 name=users
 select class=user
 list key

newlist type=racf title='Users with system-wide SPECIAL attribute'
 select listlike=users special
 sortlist key(8) pgmrname dfltgrp instdata

newlist type=racf title='Users with system-wide OPERATIONS attribute'
 select listlike=users operations
 sortlist key(8) pgmrname dfltgrp instdata
```

Generating commands using the NEWLIST command

This example shows the use of the print keywords on the NEWLIST to create RACF commands to activate user auditing for users connected to a group external to the data center.

```
newlist dd=ckrcmd nopage
   select class=user congrpnm=external
   sortlist 'ALU' key(8) 'UAUDIT'
```

The NEWLIST NOPAGE parameter is used to suppress page headers when generating commands.

OPTION

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

Use the OPTION command to modify global, print, and file options. For file option settings, the values you specify in an OPTION statement apply to all files. If you want to apply specific options to a specified file, use the FILEOPTION command. See "FILEOPTION" on page 779.

The effects of OPTION command settings depend on where the OPTION statement or command is specified in the CARLa program or command input.

- When an option setting precedes the first occurrence of a NEWLIST statement, it sets the defaults for all NEWLIST statements.
- When an option is specified in a BUNDLE statement, it specifies the settings for all NEWLIST statements that precede the matching ENDBUNDLE statement.
- When an option is specified in a NEWLIST statement or inside an OPTION statement within the NEWLIST statement, the options apply only to that NEWLIST statement.
- In a MERGELIST context, most OPTION and NEWLIST settings are taken from the first NEWLIST statement within the MERGELIST or ENDMERGE statement. The settings from the other NEWLIST statements are ignored.

ALLOWRESTRICT

When you specify the ALLOWRESTRICT keyword, CARLa queries can contain restricted fields in restricted mode. Messages CKR0170, CKR0217, CKR0384, CKR1276, CKR1382, and CKR1455 are still issued, but with a severity *4* warning message instead of a severity *12* syntax error message.

The ALLOWRESTRICT keyword is useful for running queries with restricted output fields and for complex SELECT statements with both restricted and unrestricted fields. Specifying this option setting means that you can generate some output in restricted mode. Without this option, a query with restricted fields fails because of syntax errors.

If you specify the ALLOWRESTRICT keyword in a NEWLIST statement that selects on restricted fields in restricted mode, the select operation processes the restricted fields like missing fields. In reports, the columns for restricted fields are empty.

In ISPF, issuing a query that results in no output being generated might be caused by the presence of a restricted field in the selection criteria. When no output is available, the ISPF selection panel shows the following message: CKRM948 No selections in scope. If the REQUIRED is also specified for any NEWLIST statement, the message only pertains to those NEWLIST statements. To prevent modification of a query in a manner that makes it ineffective in restricted mode, you can specify the ALLOWRESTRICT keyword for individual output fields.

You can suppress an entire query in restricted mode by specifying the UNRESTRICTED format modifier on the NEWLIST statement.

AUTODETAILSELECT

If a record display (not a summary level) has only one row/object, then the detail display is also automatically included. This behavior is not the default.

AUTOSELECT
If a summary level has only one line, then automatically select the line with S action command. This behavior is the default.

BCC= *email address list*
Sets the destination for blind carbon copy email messages. The *email address list* variable specifies the list of recipients that are confidentially copied on email messages. The value specified is a string that can be enclosed in any type of quotation marks or specified without quotation marks. The string content is interpreted as an address list conforming to the RFC (2)822 protocol, with some restrictions. For more information about the restrictions, see 860. If omitted, no RFC 2822 field BCC: is added to the email.

BUNDLEBY= *variablename*
This option setting only applies within a BUNDLE...ENDBUNDLE group and is documented with the BUNDLE statement. See "BUNDLE" on page 733. Specifying the BUNDLEBY= value on an OPTION statement that precedes the first BUNDLE statement defines the default value.

CAPS
See "CAPS" on page 780.

CC= *email address list*
Sets the destination for carbon copy email messages. The *email address list* variable specifies the list of recipients that receive an email in addition to the primary recipients specified by the MAILTO keyword.

Specify a string value for the *email address list* with or without quotation marks. The string content is interpreted as an address list conforming to the RFC (2)822 protocol, with some restrictions. For information about the restrictions, see 860. If omitted, the RFC2822 CC: field is not added to the email.

CMDTOFILE
Specify this option together with the CMD NEWLIST statement to test the CARLa query without actually issuing commands. The commands are written to the C2RCMD file. Verify that the C2RCMD file has been configured for a usable line length of 4096.

COMPAREOPT=*compareopt*
Specifies the default COMPAREOPT specification for all NEWLIST statements that do not explicitly specify the COMPAREOPT option. The *compareopt* value specified must match the name specified for a defined COMPAREOPT statement.

If a default COMPAREOPT statement has been established by the specification of the FUNCTION=BASE setting on an applicable ALLOC statement. You can use this default value by specifying value COMPAREOPT=*DEFAULT*.

ddname= *name*
DD=*name*
FILE=*name*
F=*name*
Specifies the ddname or file name for the report output. The following rules apply to the ddname specification.

- If the DDNAME keyword is used on the OPTION statement before the first NEWLIST statement, it applies to all NEWLIST statements. If the DDNAME keyword is used on a NEWLIST statement, it applies only to that NEWLIST statement.
- If the DDNAME keyword is also specified on a preceding FILEOPTION statement, the file options specified for the FILEOPTION are used.

- The following ddnames cannot be specified as a *name* value: CKRUNLIN, CKRUNLOU, STEPLIB, SYSABEND, SYSUDUMP, SYSMDUMP, CNRSAMP, CKRCARLA, CKRTSPRT, XMLIN, XMLOUT, CKRACF*, CKRSMF*.
- For some ddnames that are specified as the *name* value, the actual ddnames that are affected might be different if the file has been redirected with an ALLOC statement. This rule applies to the following ddname values: SYSPRINT, CKRCMD, CMDOUT, CNROUT, and CKR2PASS.
- When specified as a *name* value, the ddnames CKRCMD and CMDOUT are treated differently in the following respects.
  - A different command output file is used for each complex. This requires sufficient TYPE=CMDOUT files to be available using ALLOC statements.
  - TSO command line wrapping is activated and line continuation characters are used if the output record length is insufficient.
  - The sequence number fields are blank. Sequence number fields are the first 8 positions for variable record length files, and the last 8 positions for fixed record length files.

DETAILINHERIT
Echo the DISPLAY statement output for non-repeat group, non-detail fields for the currently selected object at the top of the detail display. This is the default setting for the DISPLAY output. The echo includes multiple two-line entries showing the column header line and first line for each summary-level display and the column header and first line of the object-level display output. Specifying the DETAILINHERIT keyword implies the DETAILSUMINHERIT option setting.

DETAILSUMINHERIT
Echo the DISPLAY summary and non-repeat-group fields of the currently selected object at the top of the detail display. The echo includes multiple two line entries showing the column header line and first line for each summary-level display and the column header and first line of the object-level display. Specifying the DETAILSUMINHERIT keyword implies the DETAILINHERIT option setting.

The DETAILSUMINHERIT option setting is automatically turned off when the NOSUMINHERIT keyword is specified.

DISPLAYTOFILE
When running in ISPF, treat the DISPLAY statement as if it were a SORTLIST statement. That is, write a batch report instead of creating an ISPF panel. The DISPLAYTOFILE keyword makes it possible to interactively test a query that can be specified for both ISPF and for a printed report, depending on an OPTION command in the preamble.

Note: In batch mode, a DISPLAY statement is always treated as a SORTLIST. For more information, see "SORTLIST" on page 918 and "DISPLAY" on page 778.

EGN
Format profile names as if enhanced generic naming were active. Generally, the EGN keyword option setting is not required. However, it is helpful if you have just converted from EGN to NOEGN because it can help identify profile names on the new system. The EGN keyword is not supported in restricted mode.

EMPTYLIST=HIDE
EMPTYLIST=SHOW
EMPTYLIST=*'string'*
EMPTYLIST=*"string"*

EMPTYLIST= *`string`*
EMPTYLIST=*:ISPFvar*
Specify the action to be taken when a NEWLIST statement does not generate any output, when the query returns no record selections for example. This option setting specifies both the inclusion of the NEWLIST report and the contents of the report itself. You can specify the following values.

Table 302. Empty NEWLIST output sets - Processing options

Processing option	Processing behavior
HIDE	• Suppress the empty table from the ISPF display panel. • In the SYSPRINT, do not show that the NEWLIST report was run. • Suppress the empty page from a batch report
SHOW	Displays panel or report to show that the NEWLIST statement was processed even if no output was generated. *SHOW* is the default setting for the serialization option. The display panel and report output is processed in the following manner. • Show the empty table from the NEWLIST statement on the ISPF display panel. • In the SYSPRINT, include the title for the NEWLIST report data. not show that the NEWLIST report was run. • Suppress the empty page from batch reports. In the ISPF interface, an empty table can be shown as a single line indicating zero (0) records or as a panel that only includes the header information.
SHOW stringvalue or SHOW ISPFVAR	An extension of the SHOW option, the text specified in stringvalue or by ISPFVAR is shown on the printed report.

The EMPTYLIST keyword can be abbreviated to EMPTY. For a bundle, the EMPTYLIST keyword applies to each bundle value.

ERRORMAILTO, EMT= *email address list*
If this keyword is specified in combination with the BUNDLEMAILTO keyword, reports for which no valid address is found are sent to the addresses specified in the list. This keyword also sets the addresses for the mail sender. If no FROM or SMTPMAILFROM value has been specified, the first address in this keyword also sets the default value for the SMTP MAIL FROM setting. In that case, this default value specifies the address for any error reports or delivery warnings the email server issues when routing the message. The string content is interpreted as an address list conforming to the RFC (2)822 protocol, with some restrictions. For information about the restrictions, see 860.

FIRST_PER_NAME
Suppress a NEWLIST statement if it is preceded by another NEWLIST statement with the same name. Only the first NEWLIST statement with a particular name is processed. Any subsequent NEWLIST statement with the same name is suppressed. When a NEWLIST statement is suppressed for this reason, the CKR1232 is issued.

FROM= *email address list*
Sets the From: address list for an email.

Specify a string value for the *email address list* with or without quotation marks. The string content is interpreted as an address list conforming to RFC 2822,

with some restrictions. The string content is interpreted as an address list conforming to the RFC (2)822 protocol, with some restrictions. For information about the restrictions, see 860.

If the FROM= keyword is omitted, the RFC 2822 From: field value is set to the value from the first available mail destination option. In priority order, the value is taken from one of the following keywords: SMTPMAILFROM, ERRORMAILTO, and REPLYTO.

HEADER=COLUMN
Display column headers. Do not use field prefixing. This setting is the default.

HEADER=NO, HEADER=NONE
Suppress column headers.

HEADER=PREFIX
Suppress column headers. Activate 'field comment' prefixing. See also “PREFIX” on page 800.

HELPDETAILPANEL= *panel*
DETAILHELPPANEL=*panel*
DETHELPPANEL=*panel*
Set the name of the ISPF help panel associated with a detail (repeat group) panel. The help panel is taken from the SCKRPLIB. The default is C2R&CKREREL.*nn*@0, where *nn* represents the NEWLIST type. See “FIELDS - Show CARLa fields available” on page 35.

For a NEWLIST type specified with a DEFTYPE statement, you can specify a default help panel name on the DETYPE statement. If you do not specify a value for the help panel, the value defaults to *C2R&CKREREL.NN@0*. The panel name is stored in ISPF variable CKRTHLPR. The panel name specified can contain the variable *&CKREREL*, which is replaced with *2* (for z/VM) or *3* depending on the ISPF level. but not in the first position.

HELPPANEL= *panel*
Set the name of the ISPF help panel associated with the overview panel. The help panel is taken from the SCKRPLIB. The default value is C2R&CKREREL.*nn*#0, where *nn* represents the NEWLIST type (see “FIELDS - Show CARLa fields available” on page 35).

For a NEWLIST statement type defined by a DEFTYPE statement, the default help panel name can be specified on the DETYPE statement. If you do not specify a value for the help panel, the value defaults to C2R&CKREREL.*NN*#0. The panel name is stored in ISPF variable *CKRTHLPP*. The panel name specified can contain the variable *&CKREREL*, which is replaced with *2* (for z/VM) or *3* depending on the ISPF level. but not in the first position.

LINELEN= *value*
LINELENGTH=*value*
LL=*value*
See “LINELENGTH” on page 782.

MAILfont size, MFS=
Sets the HTML font size for email. The default is 1. The HTML font size is a number in the range *1*–*7* corresponding to the following point sizes: 8, 10, 12, 14, 18, 24, and 26 point size if the browser default font is set at 12 point. The user can change the default point size.

MAILTO, MT= *email address list* **MAILTO=:***deftype.field*
Requests that the NEWLIST results are emailed to the addresses specified. This keyword must be either a string or an indirect reference to a field in a file

defined with the DEFTYPE command. See "DEFTYPE" on page 777 and "Field value manipulation" on page 760. With an indirect reference, the addresses found in each record specify the email recipients. The general RFC 2822 syntax states that an email address must include a local part, followed by an @ sign, followed by a host part, user_id@host.net for example. If the address contains other special characters for routing or other purpose, it must be enclosed in < and >, <@mailgate:user_id@host.net> for example. A list of email addresses can be specified, separated by commas.

The following restrictions apply to the RFC 2822 syntax.

1. Quotation marks are not supported within a quoted string within a phrase.
2. Line continuation within the RFC 822 string must conform to the CARLa string line continuation syntax–that is, continue on the first character of the next line. The line continuation does not conform to the RFC 822 line continuation syntax–that is, end with a comma and start the next line with a leading white space.
3. The canonized length of the phrase is limited to 512 characters. Canonized length means that white space is eliminated if it is not permitted by the RFC 821 protocol or reduced to one blank if it white space is required.
4. Phrase atoms equal to &system, &SYSTEM, or &System are replaced by the SMF system ID where the program is running.
5. Phrase atoms equal to &jobname, &JOBNAME, or &Jobname are replaced by the JES job name where the program is running.

The subject of the email is taken from the *title* or *toptitle* specified on the NEWLIST statement. This value overrides the DD and FILE specifications set previously.

Note: If *any* of the MAILTO keywords are specified, verify that the SMTPWRITER and SMTPCLASS options settings are valid, or include a C2REMAIL DD statement with an allocation to the SMTP writer. For more information, see "C2REMAIL" on page 702. You must also include at least one sender address on either the FROM, REPLYTO, SMTPMAILFROM, or ERRORMAILTO keyword. The email function of Security zSecure is not intended to be combined with the INFOPRINT email support introduced in z/OS V1R5.

MASKTYPE= *type*
Set the way filters are interpreted. The type can be either *EGN* or *ACF2*. If your product contains an ACF2 component and no RACF components, then the default setting is ACF2 masking. In the other cases, EGN masking is the default setting.

MAXP= *number*
MAXPAGE=*number*
PRTMAXP=*number*
See "MAXPAGE" on page 782.

MSGRC=(*msgno***, *level*)**
Change the severity of specific messages to the indicated value. Currently, this keyword is only supported for the following message numbers.

- *171* - Class not in descriptor table.
- *172* - ICHCNX00 problem.
- *438* - Storage shortage processing SMF.
- *2335* through *2337* - Warnings that the suppress options (for example, LICENSE=, ESM=, UNRESTRICTED) on the NEWLISTs within a MERGELIST seem to be incompatible.

- *2339* - Warning that the value for the SEGMENT parameter in a select clause in a RACF report is not known to the program.

The MSGRC keyword is only supported for the OPTION command.

MY_CCSID= *number*
Change the default EBCDIC encoding value of *1047* to the specified value. If you change the encoding, there is no guarantee that all program generated text can be read. For example, if you change the default encoding, output from the TYPE=SMF RECORDDESC NEWLIST might not be readable. The MY_CCSID keyword is only supported on OPTION statements.

NOACTION
Suppresses action characters on ISPF panels, even if the actions are available. When this keyword is specified, the action character column is not included in the panels. If this keyword is not specified, the default behavior is to analyze the permissions for each action character on a record-by-record basis. Based on the results, each record entry is made modifiable or non-modifiable. You can also use the NOACTION keyword for individual NEWLIST statements.

To turn off action characters for all NEWLIST statements in the run, specify the following setup command, `action characters allowed none`.

NOAUTODETAILSELECT
If a record-level display has only one row, do not automatically show detailed information. This behavior is the default setting because scrolling to the right on the detail does not scroll to the right on the record level display.

NOAUTOSELECT
Controls the selection behavior on summary level display panels that include only one summary line. The default behavior is to automatically select the summary line. Use the NOAUTOSELECT keyword to disable the automatic selection.

NODETAILINHERIT
Suppress automatic display of the non-detail line and its column header. Specifying this option gives the detail display more room, but leaves it to the query writer to show the object key somewhere on the display.

NODETAILSUMINHERIT
Suppresses repetition of summary information for the detail display. This behavior is implied when the NOSUMINHERIT keyword is specified

NOEGN
Format profile names as if enhanced generic naming (EGN) was *not* active. Profiles that would be supported by EGN but not by NOEGN can be found by searching for a colon (':'). This option can be helpful if you have converted profile names from NOEGN to EGN and are considering returning to the NOEGN format. You cannot specify this option in restricted mode.

NOMAIL
Turns off the email function for any NEWLIST statements that occur after this NOMAIL setting is specified. This setting turns off any default email setting specified by a preceding OPTION command.

NOMODIFY
For ISPF display panels, specify this option to make NEWLIST output read-only when it is initially shown. This parameter overrides the initial setting. After the information is shown, users can specify the MODIFY or SET MODIFY ON commands to make the display modifiable. The MODIFY setting in the application profile for the user ID is not changed.

NONULLS
See “NONULLS” on page 782.

NOPAGE
See “NOPAGE” on page 782.

NOSMTPTOFILE
Turns off SMTPTOFILE redirection for the NEWLIST. This is a local option that only applies to the current NEWLIST. If this option is specified, any output from the NEWLIST is sent by email.

NOSUMINHERIT
Disables echo behavior for the DISPLAY summary lines and headers for the currently selected object. By default, an echo is shown that includes two lines: the column header line and the first line for each summary-level display.

NOWARNING
Reset the return code to *0* when warning messages have been issued. If the internal return code is set to *4* or less as a result of warning messages, the return code is reset to *0* at the end of the CARLa run. This option is only valid on the OPTION command.

NOWTOFILE
Turns off WTOFILE redirection for the NEWLIST. This is a local option that only applies to the current NEWLIST. If this option is specified, any NEWLIST output is sent by WTO message.

NULLS
See “NULLS” on page 783.

OUTLIM= *n*
This halts output processing for subsequent LIST/SORTLIST/DISPLAY/SUMMARY command if the indicated number of records has been selected for output processing.

ONLYAT
Provides support for targeted deletion of data set profiles from nodes in an RRSF network if profiles are no longer in use by any other node in the system. The intent of the ONLYAT option is to prevent the accidental deletion of RACF database profiles that protect an existing resource.

Multi-system support can direct RACF commands through the RRSF network. In an RRSF configuration, deletion of a data set profile from any RACF database by a CARLa-generated command is not permitted if the profile is still in use by any RRSF node in the network. CARLa suppresses the generation of profile delete commands that are valid for some RRSF nodes but not all. You can override the default behavior and allow CARLa to generate profile delete commands that are directed at a specific node by using the ONLYAT option.

For this support to function correctly, system (CKFREEZE) images must be available for all systems being analyzed, either through an active zSecure Network Server connection, or by allocating them directly.

If the zSecure ONLYAT option **is not** specified, CARLa suppresses the generation of a DELDSD command if a data set profile is in use on any RRSF node in the network. A profile cannot be deleted as long as it is in use on at least one RRSF node.

If the zSecure ONLYAT option **is** specified, CARLa generates the DELDSD command that would have otherwise been suppressed and adds the ONLYAT keyword to:

- Allow deletion of a profile on a target RRSF node if the profile is no longer in use
- Prevent deletion of a profile that is in use on other RRSF-connected nodes

This keyword is specified in conjunction with the VERIFY PERMIT, VERIFY NOTEMPTY, and VERIFY ALLNOTEMPTY commands to add the ONLYAT parameter to generated RACF commands that support the ONLYAT parameter.

OUTPUTFORMAT=TEXT
OUTPUTFORMAT=EMAILDEFAULT
OUTPUTFORMAT=ATTACH

Specifies the method for including the results from a NEWLIST in an email. The following values are supported.

- TEXT includes the report inline as plain-text with limited HTML encoding. This is the only valid format for reports that are not emailed.
- ATTACH includes the report as an attachment. This is the default value for emailed XML NEWLIST data. This format is also required if UTF-8 encoding is specified.
- EMAILDEFAULT includes the report inline as MIME or HTML with limited HTML encoding. This is the default value for non-XML NEWLIST data.

OVERPRINT= *n*
OVP=*n*

See "OVERPRINT" on page 783.

PAGEALIGN= *value*

Ensures that the output from a NEWLIST statement for a specific BUNDLE value starts at a multiple of the *value* specified for the PAGEALIGN keyword. This behavior is achieved by generating empty pages at the end of the previous NEWLIST until the alignment is met. For example, if PAGEALIGN=4 is specified, the NEWLIST output can start on page *5*, *9*, or *13*, but not on page *6*. This feature can safely be combined with the PAGERESET keyword.

The PAGEALIGN= keyword is a normal OPTION setting that propagates to all NEWLIST statements. As a result, if the PAGEALIGN= keyword is specified on a BUNDLE statement, it applies to each NEWLIST statement within a specific bundle value. When applied to a NEWLIST statement outside of a bundle, the PAGEALIGN= setting applies only to that NEWLIST statement.

Note: If you specify the PAGERESET keyword in a stream of CARLa command input with multiple in combination with multiple PAGEALIGN= keywords with different values, the result might not be as expected.

PAGELENGTH= *number*
PAGELEN=*number*
PL=*number* **NOPAGE**

See "PAGELENGTH" on page 783.

PAGERESET

Reset the page number of NEWLIST output for a specific bundle value to *1* at the start of the report. You can safely combine this keyword with the PAGEALIGN= keyword on the *first* NEWLIST in the BUNDLE only, and *not* on the BUNDLE statement.

The PAGERESET= keyword is a normal OPTION setting that propagates to all NEWLIST statements. As a result, if the PAGEALIGN= keyword is specified on a BUNDLE statement, it applies to each NEWLIST statement within a specific bundle value. The best way to restart page numbering for each bundle value is to specify the PAGERESET on the first NEWLIST statement in the bundle rather than

specifying it on each NEWLIST statement within the bundle. When applied to a NEWLIST statement outside of a bundle, the PAGERESET setting applies only to that NEWLIST statement.

PREFIXLEN=*nn*
Specifies the length of the prefix headers for output from a NEWLIST statement. If this OPTION setting precedes the first NEWLIST statement, it applies to all output. Prefix headers can be included in both detail displays and print detail format output, by specifying the output modifier PREFIX or theNEWLIST option HEADER=PREFIX.

The following syntax rules and guidelines apply to the PREFIXLEN keyword.

- The minimum and default length for this value is 29.
- The maximum length for this value is *70*.
- You can specify the SYMBOLIC option to define a numeric character that represents the value as shown in the following example.
  ```
  PREFIXLEN=name|29
  ```
- If you specify a large value for the PREFIXLEN keyword, the space available for the variable output can become smaller if the value was specified with overriding length 0, which is interpreted as *until end of line* or *until end of screen*.
- You can also control the prefix length value from the NEWLIST clause in a LANGUAGE statement.

REPLYTO= *email address list*
Sets the *Reply-To:* address list for an email. The string value can be specified with or without quotation marks. The string content is interpreted as an address list conforming to the RFC (2)822 protocol, with some restrictions. For information about the restrictions, see 860. If omitted, the RFC 2822 field *Reply-To:* is set to 'Reply-To: DontReply@AutoGenerated'.

In addition, the address list can serve as a default value for the MAILFROM and FROM keywords.

REQUIRED
This option only applies when running from the ISPF interface. If the REQUIRED option is specified for any NEWLIST statement, at least one of the NEWLIST statements with REQUIRED setting must select at least one record. If this criterion is not satisfied, you are returned to the selection panel with ISPF message CKR769 Nothing selected.

SERIALIZATION(*serialization-options***)**
Specify which measures the program must take to ensure data integrity for CKFREEZE and UNLOAD data sets. Also specifies the action to take when all required resources are not immediately available. For serialization to operate properly, all jobs involved must specify the same resource name. That is, all jobs must specify the same value for the ENQ request. All jobs must also access data sets under their true names. Do not use aliases because a successfully acquired alias does not guarantee that the data set is available under its true name. The following values can be specified for the serialization options.

ENQ(*qnames***)**
Serialization option to provide data integrity and input data availability by specifying that the program issue the appropriate ENQ request. You can specify the following subparameters to indicate the desired type of processing.

CKRDSN
The program issues a sysplex-wide ENQ with this QNAME for all CKFREEZE

data sets, UNLOAD data sets, and SMF data sets for processing. The ENQ is shared for data sets that are read-only. It is exclusive for data sets that the ENQ writes to. This method guarantees that no other process attempts to refresh an UNLOAD or read a CKFREEZE data set while the data set is being processed.

SYSDSN
The program issues a system-wide shared ENQ request with this QNAME for all data sets it processes except for the following types.

- Data sets allocated as TYPE=INPUT.
- CARLa input data sets like the CARLa script library.
- non-critical output data sets like SYSPRINT and SYSTERM

This ENQ request is intended to be specified in combination with the WAIT serialization option so that the program can wait until all required data sets are available. Alternatively, you can specify the SYSDSN keyword in combination with the FAIL serialization option. If all the data sets are not immediately available, an error message is issued and processing ends. Issuing an ENQ request for QNAME SYSDSN requires that the program be APF-authorized.

This option is mutually exclusive with the NOENQ keyword.

FAIL
This serialization option specifies that the program is to stop further processing if the data sets for which an ENQ is requested are not immediately available. This option is mutually exclusive with WAIT. If neither is specified, FAIL is the default.

MAXWAIT(*nn*)
This serialization option specifies the maximum time the program waits for the data sets for which an ENQ is requested to become available, in minutes. Supported values are in the range *1 – 59*, inclusive, with a default value of 5 minutes. The MAXWAIT setting is only effective when it is specified in combination with the WAIT serialization option.

NOENQ
Specifies that no ENQ requests are to be issued. This option is mutually exclusive with the ENQ serialization option.

UNIT
Specifies that dynamic allocation is not performed until a unit becomes available to satisfy the allocation request. This setting applies mostly to tape data sets. This option requires that the program be APF-authorized.

VOLSER
This serialization option specifies that, if need be, dynamic allocation is not performed until the required *volser* becomes available. It applies mostly to tape data sets. This option requires that the program be APF-authorized.

WAIT
Specifies that the program is to wait until the data sets specified in an ENQ request are available. This option is mutually exclusive with the FAIL serialization option. If the program is APF-authorized, specify the MAXWAIT serialization option to set a maximum wait time. An unauthorized program can only wait for the specified time period to expire.

By default, the program uses the following settings for the SERIALIZATION keyword: SERIALIZATION(ENQ(CKRDSN),FAIL.

ServerToken=*ServerToken*
Keyword that specifies the 8-character suffix for the name of the name/token pair used for locating the Program Call (PC) information for the zSecure Server. The value specified is prefixed by the value *CKNSERVE*. The default value for ServerToken is *PRODSERV*. If this keyword is not specified, the default value is used. Specifying a value for the ServerToken is only required if you are running multiple zSecure servers on the same system, or if the value for the zSecure server has been changed from its default value.

SETROPTS_REFRESH_ON_END
Generate interactive SETROPTS REFRESH commands for selected profiles at the end of the CARLa run. This option is only valid on the OPTION command.

SMTPCLASS= *sysoutclass*
See "SMTPCLASS" on page 783.

SMTPMAILFROM= *email address list*
Specifies the email address list for routing emails. The first address in the list sets the RFC (2)821 SMTP header MAIL FROM address for emails. Email servers along the delivery route send error reports and delivery warnings to the specified address. In addition, the full address list can serve as a default for the FROM address.

Specify the email address as a string enclosed with any type of quotation mark or specified without any quotation mark. The string content is interpreted as an address list conforming to the RFC (2)822 protocol, with some restrictions. For information about the restrictions, see 860. If omitted, the RFC 2821 field *MAIL FROM* is completed from the first available option in the order FROM, REPLYTO, and ERRORMAILTO. To send email, at least one of the following four options must have been specified: SMTPMAILFROM, FROM, REPLYTO, or ERRORMAILTO.

SMTPNJENODE= *nodename*
See "SMTPNJENODE" on page 783.

SMTPTOFILE
This option can be set to redirect email (SMTP) output. The default destination is DD C2RSMTP. Only output generated as the result of a MAILTO or BUNDLEMAILTO keyword is redirected. It is meant for testing purposes, to be specified preceding the first NEWLIST statement. If specified on or after a NEWLIST, it only applies to an email specification on that NEWLIST.

SMTPWRITER= *name*
See "SMTPWRITER" on page 783.

SNMPTO= *destination:port*
SNMPTO=(*destination:port***,***destination:port***, ...)**
If the SNMPTO= keyword specification precedes the first NEWLIST statement or on a NEWLIST statement that specifies the SNMP option, it determines the output destination for SNMP traps. If SNMPTO= is omitted, the default destination for SNMP output is the normal file output in file C2RSNMP by default.

The destination can be a name looked up through DNS or an IP address. The destination can be followed by an optional colon and port specification in decimal form. If the destination is an IPv6 address containing at least one colon character and it is followed by a colon and a port specification, enclose the value in square brackets. For example, [::1]:1169 where ::1 is the IPv6 address and 1169 is a port number. This specification is different from ::1:1169, where 1169 is the last part of the IPv6 address ::1:1169, and where no port specification is present. Square brackets around an IP address are optional if the address is not followed by a port specification or if the address is IPv4.

SYSLOGTO= *destination:port*
SYSLOGTO=(*destination:port,destination:port, ...***)**
If the SYSLOGTO= specification precedes the first NEWLIST statement or if it is specified on a NEWLIST statement that specifies the SYSLOG option, it determines the output destination for SYSLOG traps.

The destination can be a name from a DNS or IP address lookup. The default port is 514. For more information, see the SNMPTO= parameter description.

If SYSLOGTO= is omitted, the default destination for SYSLOG output is the normal file output in file C2RSYSLG by default.

SNMPTOFILE
Redirects SNMP output. The default destination is DD C2RSNMP. Only output generated as the result of an SNMP keyword is redirected. The SNMPTOFILE keyword is helpful for testing output.

Make sure the SNMPTOFILE keyword precedes the first occurrence of the NEWLIST statement. If specified on or after a NEWLIST statement, the keyword applies only to the SNMP specification for that NEWLIST statement. For this keyword, the RECFM and LRECL settings for the C2RSNMP file are used, which default to a logical line length of 132 bytes for printed output files. To simulate the line length used when writing SNMP traps, you need an effective line length of 1056 bytes and therefore you must specify values of RECFM=VB,LRECL=1060 for the C2RSNMP allocation.

SUMHELPPANEL= *panel* **HELPSUMPANEL=***panel*
Set the name of the ISPF help panel associated with the summary panel. The help panel is taken from the SCKRPLIB. The default is the value of HELPPANEL. The value is stored in ISPF variable CKRTHLPS. The panel name specified can contain the variable *&CKREREL*, which is replaced with *2* (for z/VM) or *3* depending on the ISPF level. but not in the first position.

SUMINHERIT
Echo the DISPLAY summary line and header of the currently selected object at the top of the record display. The echo includes a multiple of two lines: the column header line and first line for each summary-level display. It is on by default.

SYSLOGTOFILE
Redirects output to the default syslog file C2RSYSLG. You must specify this keyword before the first NEWLIST statement. Only output generated as the result of a SYSLOG keyword is redirected.

Use the SYSLOGTOFILE keyword to send syslog output to a file for testing. When you specify this keyword, the LRECL and RECFM settings for the C2RSYSLG file are used, which default to a logical line length of 132 bytes for printed output files. To simulate the line length used when writing syslog output, specify RECFM=VB,LRECL=2048 for the C2RSYSLG allocation. If you specify SYSLOGTOFILE on a NEWLIST statement, the redirection applies only to that NEWLIST statement.

TOPTITLE,TT
TITLE,T
SUBTITLE,ST
PAGETEXT
See "(TOP)TITLE" on page 783.

UNRESTRICTED
NONPADS
Specifies that the NEWLIST statement is only processed if the program is running

in unrestricted (non-PADS) mode. Otherwise, ignore the NEWLIST statement and the commands within its context. Because the commands are skipped, no error message is issued.

Note: You can use the ALLOWRESTRICT keyword to suppress output from restricted fields in restricted mode instead of suppressing the entire query.

WTOTOFILE
This option can be set to redirect WTO output. The default destination is DD C2RWTO. Only output generated as the result of a WTO keyword is redirected. Use the WTOTOFILE keyword for verifying WTO output during the test process. If this keyword precedes the first NEWLIST statement, the setting applies to all NEWLIST statements that do not specify the setting directly. If the keyword comes after the first NEWLIST statement, it only applies to a WTO specification on that NEWLIST statement.

Example - Defaults set by OPTION commands

The following command set the default ddname for the output from all NEWLIST statements to *MYREPORT*. It sets the default line length for all NEWLISTs to *64*.

```
option dd=myreport ll=64
```

When these options have been set, the output from the example OPTION statements shown in this code example might not behave the way you expect.

```
option dd=myrepor1 ll=64
option dd=myrepor2 ll=132
```

The first option command sets the default ddname for all NEWLIST statements to MYREPOR1 and sets the default line length to 64. The second, changes the default ddname to MYREPOR2 and the line length to 132. In effect, the first option command is ignored. When you specify these settings with the OPTION command, the settings apply to all subsequent NEWLIST statements. To specify different ddname and line length values or other file option settings for specific NEWLIST statements, use the FILEOPTION statement.

Example - Redirecting report data

You can generate a separate file containing the security profile information from Security zSecure, for postprocessing, with SAS for example. To accomplish this task with the NEWLIST statement, direct the LIST command output to a separate file as shown in the following CARLa statements.

```
newlist ddname=listout
  select class=user
  list key(8) pgmrname instdata
```

These commands generate a file populated with User profile information.

Example - titles

When you generate multiple reports, you can configure a different title for each report. The following example generates a report with the TOPTITLE, TITLE, and SUBTITLE keywords specified in combination with two NEWLIST commands. The OPTION settings specified outside the scope of a NEWLIST serve as a default for each new list.

```
OPTION TOPTITLE='ABC Computer services Inc, phone 234-17829',
      TITLE='Security zSecure report output'
NEWLIST
   OPTION SUBTITLE='Users with system-wide SPECIAL attribute'
   SELECT CLASS=USER, SPECIAL
   SORTLIST KEY(8) PGMRNAME DFLTGRP INSTDATA
NEWLIST
   OPTION SUBTITLE='Users with system-wide OPERATIONS attribute'
   SELECT =USER, OPERATIONS
   SORTLIST KEY(8) PGMRNAME DFLTGRP INSTDATA
```

PRINT

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

The PRINT command is equivalent to the OPTION command, except that it does not support non-print options like MY_CCSID, MSGRC, and SETROPTS_REFRESH_ON_END. For further information, refer to “OPTION” on page 856.

The PRINT command can be abbreviated as P.

REMOVE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
		•	•			

The REMOVE command generates RACF commands to remove users, groups, permits or notify fields. In the presence of one or more CKFREEZE files, the Remove operation also generates commands to delete data sets covered by removed profiles, data sets not covered by any profile, and catalog aliases having the sourceid as HLQ (migrated data sets only if cataloged and tape data sets not at all).

The REMOVE command does not issue any commands by itself. The generated RACF commands are written to the CKRCMD file.

Usage notes

- Commands in the CKRCMD file can also be generated as the result of the following commands: MOVE, REMOVE, VERIFY or PRINT DD=CKRCMD .
- If commands are being queued from the interface, then commands in CKRCMD can also be generated by overtyping, including the extra SETROPTS REFRESH commands.

To complete the REMOVE operations, verify and confirm the commands from the CKRCMD file, and then run them.

The command syntax for the REMOVE command is similar to the syntax for the COPY and MOVE commands.

When the REMOVE command runs, the resulting messages are similar to those generated by the COPY and MOVE commands except that they use the term

Remove or or Delete instead of Copy or Replace. Any IDCAMS commands created by the REMOVE command generate messages that use the term *Resource deletion:*.

The keys and members of RACFVARS. profiles are by default interpreted as users and groups when they match a valid user or group id, and they are managed accordingly, unless you run the SUPPRESS MANAGERACFVARS command. A discrete first qualifier in the key of a STARTED profile is only interpreted as a user ID when it matches the specification in the STUSER field in the STDATA segment.

The Resource deletion: commands might include ALLOCATE and FREE commands to delete uncataloged (non-VSAM) data sets. TSO supports these commands, but they cannot be issued directly to IDCAMS. You can exclude these commands by specifying SUPPRESS DELETEUNCATALOGED, which will list the VTOC entries concerned in the SYSPRINT as kept.

If a CKFREEZE file is specified and you do not want to generate any resource deletion commands, specify SUPPRESS DELETEDATASETS for the run. If you issue this command, the CKFREEZE file is not read unless other commands require it. Otherwise, DELETE commands are issued against all cataloged disk data sets and cataloged migrated or archived data sets covered by the profiles subsequently deleted. The actions are also issued against unprotected or inaccessible data sets that have the removed ID as the HLQ and the corresponding catalog aliases. The DELETE commands are generated with the PURGE option to override any expiration settings. As a general rule, the NOSCRATCH option is only specified where necessary. You can suppress the NOSCRATCH commands entirely using the SUPPRESS DELETENOSCRATCH command. Because zSecure does not automatically clean up VSAM inconsistencies or orphan NVRs. check the VSAM or VVDS inconsistencies message category if you must take these issues into account.

In case of shared DASD, the commands are generated for the current system and might not work correctly when submitted on a different system. In addition, as much configuration is removed as possible. For example, catalog aliases in inactive or remote master catalogs are removed. Be cautious when using the REMOVE command, particularly if there are unconnected catalogs. If you have partially shared DASD, make sure to supply additional CKFREEZE data sets to inform the run about the DASD that does not belong to the current system. You might have to do some additional work from another system later on with updated CKFREEZE data sets. For details on excluding specific volumes or catalogs and other information, see the "SUPPRESS" on page 932 command documentation.

For more information, see the following sections.

- "REMOVE parameter descriptions"
- "Using the REMOVE command" on page 874

REMOVE parameter descriptions

The REMOVE command has three parameter types: users/groups to be processed, modifiers for the processing parameters, and independent parameters.

- "User and group processing parameters"
- "Modifier for user and group processing" on page 873
- "Independent parameters for the REMOVE command" on page 873

User and group processing parameters

The following group of user and group processing options are mutually exclusive on any single REMOVE command. To use more than one of these parameters,

specify a separate REMOVE command for each parameter. In addition, these parameters are mutually exclusive with VERIFY PERMIT and VERIFY STC.

PERMIT= *idlist*

The value specified for the *idlist* can be a single user or group name or a list of user or group names that is enclosed in parentheses and separated by commas.

To prepare the users or groups specified in the *idlist* for removal, the PERMIT parameter generates commands to remove references to user and group IDs from the following resources: access lists, OWNER fields, SUPGROUP fields, NOTIFY fields, RESOWNER fields, certain APPLDATA fields, STUSER and STGROUP fields, NODES members, and functional positions in profile keys and members of the following classes.

- DATASET
- DLFCLASS
- INFOMAN
- CICS: TCICSTRN, GCICSTRN, DCICSDCT, ECICSDCT, FCICSFCT, HCICSFCT, ACICSPCT, BCICSPCT, JCICJCT, KCICSJCT, MCICSPPT, NCICSPPT, PCICSPSB, QCICSPSB, SCICSTST, UCICSTST, CCICSCMD, VCICSCMD
- VM: VMMDISK, VMRDR, VMBATCH

The scope of the command can be limited by the `FROMGROUP`, `TOGROUP`, and `ALLPERMITS` parameters as well as by the `STUSER` and `STGROUP` and `RESOWNER` fields, and to change profile ownership, `SUPGROUP` fields, certain `APPLDATA` fields, and `NOTIFY` fields as appropriate. Profile ownership is changed based on the following criteria.

- For group data set profiles, ownership is changed to the first qualifier, as changed by ICHCNX00.
- For connect profiles, ownership is changed to the owner set by the command `DEFAULT OWNER=` . The default is `SYS1`.
- For other profiles, NOTIFY fields are removed unless the NEWNOTIFY parameter is used to indicate which user should replace the one to be removed.

NOTIFY= *id*

The NOTIFY parameter specifies a subset of `REMOVE PERMIT=` processing that is limited to NOTIFY fields.

USER= *idlist*

The USER parameter removes one or more users from the database or from a number of groups, including all references and the profiles used only for a single user. The groups are specified using the FROMGROUP parameter. The USER parameter specifies all processing for `REMOVE PERMIT=` and also generates the RACF commands to remove users from their connect groups, delete the user profiles if requested, and modify the default groups of the users as needed.

The value specified for the *idlist* can be a single user name or a list of user names that are enclosed in parentheses and separated by commas.

GROUP= *idlist*

The GROUP parameter removes one or more groups from the database, including all references and profiles used only for a single group. The GROUP parameter specifies all processing for `REMOVE PERMIT=` and also generates the RACF commands to remove users from groups, delete group profiles if requested, and modify default groups of users as needed. However, GROUP parameter processing does *not* automatically delete user profiles if a group is

the last remaining group for a user. For these types of user profiles, the remove commands generated will fail when they are run.

The value specified for the *idlist* can be a single user name or a list of user names that are enclosed in parentheses and separated by commas.

Modifier for user and group processing

The following parameters can be used to adjust the processing performed by the user and group processing parameters described in "User and group processing parameters" on page 871.

FROMGROUP= *idlist*
The FROMGROUP parameter limits the scope of the removal to the groups specified in *idlist*. The value specified for the *idlist* variable can be a single group name or a list of group names enclosed in parentheses and separated by commas. This limitation of scope also extends to the data set profiles of the group: removal of access lists, owner fields, and so on, is only done for profiles belonging to one of the groups in the list (either by their first qualifier or the qualifier returned by ICHCNX00).

TOGROUP= *idlist*
The TOGROUP parameter limits the scope of removal for a specified group or list of groups to exclude the personal data set profiles for a user, the group DATASET profiles for groups in the TOGROUP idlist, and all general resource profiles. The value specified for the *idlist* can be a single group name or a list of group names enclosed in parentheses and separated by commas. The TOGROUP parameter is only valid with the `REMOVE USER=` command. This parameter specifies a group (or list of groups enclosed in parentheses and separated by commas). If the ALLPERMITS parameter is added, the profiles and references for the user in the general resource profiles are also removed.

ALLPERMITS
This parameter is valid only when specified after the TOGROUP parameter. The ALLPERMITS parameter causes references in all profiles to be removed, except for those profiles for group(s) specified in the TOGROUP parameter. This includes removing the profiles and general resource profiles for the user that would not be removed if the ALLPERMITS parameter is not specified. The main use for the ALLPERMITS parameter is to move a user to a *'holding group* before deleting it permanently. See the REVOKE parameter description.

NEWNOTIFY= *id*
The NEWNOTIFY parameter indicates the replacement user ID to be used for the NOTIFY fields processed by the user/group removal commands.

REVOKE
The REVOKE parameter can be used on the REMOVE USER= command to revoke the user ID as well as performing the other actions on the REMOVE command.

Independent parameters for the REMOVE command

The following REMOVE options are independent functions.

REDUNDANT
The REDUNDANT parameter removes discrete data set profiles that are covered by a generic profile whose OWNER, WARNING, ERASE (where active globally), and audit settings are identical or can be considered *similar*. Access is considered *similar* if the access list contains the group to which the data set belongs with a lower level than present in GLOBAL DATASET member

&RACGPID.*. Access is also considered *similar* if a user ID is present on the discrete profile access list with an access that is also granted via one of the groups to which the user ID is connected. You can use the LIMIT DISCRETE and LIMIT GENERIC commands to process only discrete or generic profiles. See "LIMIT" on page 787.

REDUNDANT_PERMIT
Generate commands to remove permits to users that would have the same access just through their current set of connect groups. Processing is done separately for conditional and non-conditional access lists.

Warnings

- The REDUNDANT_PERMIT function assumes that list-of-group checking is active. If you do not have SETROPTS GRPLIST set, do not use this function.
- REDUNDANT_PERMIT does not take into account future connect revoke dates. That is, a user permit is deleted even if the connect to the group with the same access has a future revoke date set. User permits are deleted if both of the following are true.
  1. The access level is at most the access the user currently has for all groups connected to the user. (That is, the user permit does not lower the authority that would be granted through connect groups.)
  2. At least one other connect group gives exactly the same access when the connect group is not revoked at the database unload date.

Note: All parameters can also be specified as parm(value) in addition to parm=value.

Using the REMOVE command

The parameters and other options you use with the REMOVE command depend on the context of the resources you want to remove. Table 303 provides examples of using the REMOVE command. For details on the parameters specified in the examples, see "REMOVE parameter descriptions" on page 871.

Table 303. REMOVE command examples

Task	Code sample	Description
Removing references	`remove permit=jones`	Generates the commands to remove all meaningful references to the specific user ID or group *JONES* from the RACF database. For details on the PERMIT parameter, see "User and group processing parameters" on page 871.
Removing a user	`remove user=jones`	Generates commands to remove the user ID *JONES* from the database, including all personal profiles that belong to the user. For details on the USER parameter, see "User and group processing parameters" on page 871.
Removing redundant profiles	`remove redundant limit discrete`	Generates commands to remove redundant discrete data set profiles For details on the REDUNDANT parameter, see "Independent parameters for the REMOVE command" on page 873.

REPORT

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
		•	•	•	•	

After performing a scan of the security database and optional CKFREEZE files, this command requests reporting functions based on analysis of the data. The reports are created after the scan finishes. This processing is in contrast to the LIST command that is performed *during* the scan.

The REPORT command requires much more memory than the LIST function. It is mutually exclusive with the MOVE and REMOVE commands. You can issue multiple REPORT statements when you run the program. However, there are some restrictions on using the parameters. For more information, see "REPORT parameters."

Report layout

The report layout is determined by the default layout for the specified NEWLIST type. If a REPORT *report* is requested and no corresponding NEWLIST TYPE=REPORT_*report* has been encountered, the program uses a default report layout that is compatible with earlier versions of the product. This layout is defined by the CARLa member CKRR *type*. This format does not support reporting on multiple complexes in one run. For a report that has complex names use the IMBED M=CKRL *type* instead, or the CKRD *type* to show data in ISPF. See "Report layouts" on page 252.

To avoid using the default report layout, the NEWLIST TYPE=REPORT_<*type*> must be present in the input CARLa statements before the REPORT <*type*> command.

REPORT parameters

The REPORT command provides parameters for selecting records to be included in the report based on criteria like profile type, access level, and scope. You can also add modifiers to the REPORT command to control the report output formats. For examples, see "Using the REPORT command" on page 883.

For information about parameter descriptions, see the following topics.

- "PERMIT, SCOPE, and ACCESS level"
- "Mutually exclusive REPORT parameters" on page 878
- "Data set, resource, and attribute options" on page 879
- "Report data sort order" on page 882
- "Page headers" on page 882

See the following parameter descriptions, for information about the parameters including descriptions, syntax, and any processing considerations.

PERMIT, SCOPE, and ACCESS level

Use the following parameters to report on resources by user of group ID and access level.

PERMIT= *ID*

Reports resources to which the specified user or group has access through an explicit reference in the access list or OWNER field, also known as *direct* access.

- The ACCESS parameter limits the report output to profiles that the *ID* can access at least at the specified level, ACCESS=UPDATE for example.
- You can create a report showing access to defined RACF users, who are otherwise not on the access list by specifying * for *ID*
- You can specify more than one PERMIT parameter.
- PERMIT is mutually exclusive with SCOPE.
- In a report run, you can specify multiple REPORT PERMIT parameters or multiple REPORT SCOPE parameters, but not a mixture of the two.
- If a NEWLIST TYPE=PERMIT command is not present before the REPORT command, then a single-complex default layout is included which is the CARLa member CKRRSCOP. See "Report layouts" on page 252.)

SCOPE= *ID*

Reports resources to which the specified user or group has direct or indirect access. The ACCESS parameter limits the output of the SCOPE parameter to profiles that the *ID* can access at least at the specified level, ACCESS=UPDATE for example. If *ID* is a user, access through connects is also listed. Access through universal access, data set global access table, and missing profiles with NOPROTECTALL is included with the correct exceptions, unless the reasons UACC, GLOBAL, and NOPROFILE are suppressed.

- If a profile has a warning attribute, it is considered equivalent to having ALTER access to the profile, unless the reason WARN is suppressed.
- Group-special, group-operations, and group-auditor attributes are propagated down the group tree to resources owned by owned groups and to resources owned by users owned by owned groups, unless the reasons GRPSPECIAL, GRPOPER,, GRPOPER,or GRPAUDIT are suppressed.
- The SCOPE parameter can use much more memory than the PERMIT= parameter. By specifying the value * for *ID*, a report is created showing the scope of jobs without a RACF user and other users that are given access based on the UACC. The number of profiles listed can be reduced by including the SUPPRESS REASON= command or by specifying the ACCESS parameter. (See "SUPPRESS" on page 932.)
- If you specify multiple SCOPE parameters, add PAGEBY=ID to the REPORT command so that the page header of the report lists the ID. If a NEWLIST TYPE=REPORT_SCOPE is not present before the REPORT command then a single-complex default layout is included, CARLa member CKRRSCOP. See "Report layouts" on page 252.)

ACCESS= *level*

Specifies the minimum level of access. Use this parameter with the PERMIT or SCOPE parameter. You can also specify the ACCESS parameter for the AC1 and STC reports. The parameter applies globally for all REPORT options present and can only be specified once.Table 304 on page 877 lists the access levels you can specify, listed from highest level to the lowest level.

Note: For general resource classes where both the member class and the grouping class contain the same (member) resource, the SCOPE command processes the profiles the same way that RACF processes them; each profile is considered separately. This processing can result in the member resource having a different access level than the access level determined by a RACF FRACHECK command.

Table 304. Access levels and their meaning

Level	Meaning
OWNER	Authority through ownership.
QUALOWN	Authority based on the first qualifier of a data set profile. If the data set HLQ is a user ID, this user has QUALOWN authority. Otherwise, if the data set HLQ is a groupid, any user with group-special for this group has QUALOWN authority.
CREATE	CREATE authority - a more specific profile can be created.
ALTER-M	ALTER access on 'myself' - a user can alter some fields in their own user profile.
ALTER-P	ALTER access on a discrete profile (allowing you to issue PERMIT).
CKGOWNR	Access granted by the CKGRACF authorized component of IBM Security zSecure Admin through the CKG.SCP scope profiles. Exactly what can be changed further depends on CKG.CMD profile access. This can only be more access then standard RACF, not less.
ADMIN	Same as CKGOWNR.
CNGOWNER	Same as CKGOWNR.
ALTER-O	ALTER access caused by a group-operations attribute.
ALTER	ALTER access.
AD_READ	ADD, DELETE, and READ authority through a controlling profile in the FACILITY or XFACILIT or similar class.
ADD_DEL	ADD and DELETE authority through a controlling profile in the FACILITY or XFACILIT or similar class.
ADD	ADD authority through a controlling profile in the FACILITY or XFACILIT or similar class.
ADD-S	Limited ADD authority through a controlling profile in the FACILITY or XFACILIT or similar class.
CONTROL	CONTROL access.
D_READ	DELETE and READ authority through a controlling profile in the FACILITY or XFACILIT or similar class.
DELETE	DELETE authority through a controlling profile in the FACILITY or XFACILIT or similar class.
DELETE-S	Limited DELETE authority through a controlling profile in the FACILITY or XFACILIT or similar class.
UPDATE	UPDATE access.
READ	READ access.
READ-S	Limited READ authority through a controlling profile in the FACILITY or XFACILIT or similar class.
READLPA	The UACC does not allow READ, but the module can be read in the LPA.
LOADEXE	The UACC does not permit READ, but the module can be run, and it can be read using LOAD.
EXECUTE	`EXECUTE` access for running a module
COPY	A module can be read, but not run. If the operation does not depend on APF or library residence, then anyone can access its function by copying it to their own load library.
AUDIT	Audit access without any other access.

Table 304. Access levels and their meaning (continued)

Level	Meaning
HIDDEN	A PDS member or load module hidden by a similarly named member in a library in front of this library.
NONE	No access.

Mutually exclusive REPORT parameters

The REPORT parameters in the following list are mutually exclusive.

NONREDUNDANT
Lists all data set profiles that are different from a less specific generic profile, if any exists. These profiles are considered nonredundant because removing them changes the data set access. If they were redundant, removing them would have no effect on the access level. Profiles are non-redundant when they fit any of the following criteria.

- Profile is a top level generic profile.
- Closest less specific generic profile has different WARNING, effective, AUDIT, or ERASE [7]
- The access list is different from a less specific generic profile.

  Similar access lists are defined by one of the following conditions. 1) All users effectively have the same access on either profile. This condition might exist if the access list contains the group to which the data set belongs with a lower access level than the one specified in the GLOBAL DATASET member &RACGPID.*. 2) A user ID is present on the profile access list with an access that is also granted through one of the groups to which the user ID is connected.

In the report, the column marker **First reason** indicates why this profile was included in the report. If there are multiple reasons, only one reason is indicated. Text enclosed in hyphens does not indicate non-redundancy by itself, it is a marker to help interpret the report. For example, the text - candidate - identifies a profile that was compared with more specific profiles listed later in the report. The profile is considered a *candidate profile* because it can take over the function of a more specific, potentially redundant profile. See "RA.3.2 Non redundant - Data set profiles different from less specific profiles" on page 201. If a NEWLIST TYPE=REPORT_REDUNDANCY is not present before the REPORT command then a single-complex default layout is included, CARLa member CKRRNONR. See "Report layouts" on page 252.NEWLIST TYPE=REPORT*report*

REDUNDANT
Lists the redundant profiles and the candidate profiles making them redundant. For the selected profiles, this parameter provides the same information reported by the NONREDUNDANT parameter. If a NEWLIST TYPE=REPORT_REDUNDANCY command is not present before the REPORT command then a single-complex default layout is included, CARLa member CKRREDUN. See "Report layouts" on page 252.

NONDEFAULT
Report all profiles with non-default access control. Generally, each installation has its own defaults, which are part of the security policy. However, Security zSecure tries in a general way to report about profiles that deserve consideration. The following list describes the default conditions for different user and group data sets.

7. Erase-on-scratch is not considered if ERASE(ALL) or NOERASE global options are active. ERASESECLEVEL is not supported.

- For *User data sets*, default indicates the following. The owner field equals the first qualifier; there is no access list, and the UACC is NONE.
- For *Group data sets with a user as owner*, default indicates the following. The user ID is in the access list with ALTER, and the group data set qualifier, which is the first qualifier unless altered by ICHCNX00, is in the access list with UPDATE.
- For *Group data sets with a group as owner*, default means that the owning group is in the access list with ALTER.

If a NEWLIST TYPE=REPORT_NONDEFAULT is not present before the REPORT command then a single-complex default layout is included, CARLa member CKRRNOND. See "Report layouts" on page 252.

OUTOFGROUP

Reports all outstanding permits on group data sets to users or groups outside that group (identified by the first qualifier unless changed by ICHCNX00). If a NEWLIST TYPE=REPORT_OUTOFGROUP is not present before the REPORT command then a single-complex default layout is included, CARLa member CKRROUTG. See "Report layouts" on page 252.

For all report parameters (PERMIT=, SCOPE=, ACCESS=, NONREDUNDANT, REDUNDANT, NONDEFAULT, and OUTOFGROUP), you can limit the report to a subset of all profiles by using the SELECT or EXCLUDE statement. If you do limit the report, avoid excluding USER, CONNECT, GROUP, or GLOBAL profiles. In addition, to limit the report to only certain DATATSET profiles, you must ensure that all DATASET profiles are selected for the qualifier on which you want to report. For example, to report on the redundancy qualifier for the DATASET profile SYS1.PARMLIB, you must include all SYS1 DATASET profiles in the analysis.

Data set, resource, and attribute options

Use these options to include the following types of data in the report.

- The DATASET classes covered by the RACF profiles that were selected using other report parameters.
- The resource classes, other than the DATASET class, covered by the RACF profiles using other report parameters.
- Detailed profile information for the selected DATASET and resource profiles.
- Tape data sets that are currently in scratch status.
- Protection of load libraries that have the potential to circumvent the security system.
- The protection of load modules that are covered by program profiles present on the conditional access list of any data set profile.
- All data set profiles, GLOBAL DATASET members, and missing High-level qualifier (HLQ) generics that cover sensitive data sets that require protection. HLQ generics are of the form *user.*** or *group.***.

You can specify the following options combined with each other and with the previous options. To use these options, you must a currently selected CKFREEZE file for the input data source.

These options do not produce the correct results if you have excluded any of the following resources from the selection.

- Any profiles in the class DATASET starting with the same qualifier as the data set selected for analysis.
- The GLOBAL DATASET general resource profile.

- Any PROGRAM profiles for AC1.

The following list describes the parameters available for reporting.

DATASETS
DATASET
DSN
Report which data sets are covered by each RACF profile reported by the following REPORT parameters: PROFILES, SCOPE, NONDEFAULT, NONREDUNDANT, OUTOFGROUP, or SENSITIVE. For SENSITIVE profiles, the selection includes *all* data sets covered by generic profiles. Without this keyword, only the sensitive data sets are shown.

RESOURCE
RESOURCES
Report which resources other than data sets are covered by each RACF profile reported by PROFILES, or SCOPE. This parameter only applies to resources deemed sensitive. Sensitive resources can occur multiple times–once per access level that has a separate sensitivity. This keyword requires an AUDITRACF or AUDITACF2 entitlement.

SCRATCH
SCR
Reports on tape data sets that are currently in scratch status. You must specify this parameter in combination with the DATASET parameter. For CA1, this parameter applies only to the first data set name on tape, not to secondary data sets in a multi-volume complex. In the cases of TLMS and RMM, all files on a scratch tape can be present. This option is not supported in restricted mode.

PROFILES
PROFILE
Report the class, key, access list, owner, auditing, conditional access list, and erase status of all selected profiles for the class DATASET and the general resource classes. If a NEWLIST TYPE=REPORT_PROFILE is not present before the REPORT command then a single-complex default layout is included, CARLa member CKRRPROF. See "Report layouts" on page 252.

AC1

Report on the protection of load modules that have the potential to circumvent RACF. The following list shows the load module types considered for selection.

- The AC(1) members of all APF libraries with all their entry points.
- Modules in APF libraries that are present in the Program Property Table (PPT) with the BYPASS option or a *system key* (0-7).
- Modules in APF libraries that are present in the RACF authorized caller table with RACINIT or RACLIST authorization.
- Authorized I/O appendages.

The report includes the highest access to arbitrary users as given by the combined action of the following resources: PROGRAM profile UACC, DATASET profile UACC, link list residency, LPA residency, global access table, and the profile warning mode. You can specify the ACCESS=*level* parameter for selecting only those modules with a UACC of *level* or higher.

The report also shows the following information.

- All module occurrences with link list and LPA list concatenation numbers.
- In-storage MLPA residency.
- Base member names for alias entries.

- The RACF data set and program profile names.
- The authorizing attributes, and attributes extending the authorization to the TSO environment (AuthCMD, AuthPGM, and AuthTSF).

This report extends beyond column 132, and is truncated if using the default line length. However, the last field is the data set profile name. Depending on the length of your profile names, most profile names fit on the default line length. You cannot create the report for AC1 data if the product is operating in restricted mode. If a `NEWLIST TYPE=REPORT_AC1` is not present before the `REPORT` command then a single-complex default layout is included, CARLa member `CKRRAC1`. See "Report layouts" on page 252.

PADS

Report on the protection of load modules that are covered by program profiles present on the conditional access list of any data set profile. The output format is like the format described for REPORT AC1. You cannot create the report with PADS data if the product is operating in restricted mode. If a `NEWLIST TYPE=REPORT_PADS` is not present before the `REPORT` command then a single-complex default layout is included, CARLa member CKRRPADS.See "Report layouts" on page 252.

STC

Report on the protection of started tasks.

The report combines information from the following resources.

- Started Procedure Table ICHRIN03.
- The RACF database including the RACF 2.1 STARTED class.
- The JES2 procedure library concatenation in use for started tasks.
- The procedure library used by the master address space (MSTR subsystem).

You can specify the `ACCESS=`*`level`* parameter to select only those modules with a `UACC` of *level* or higher. You cannot create the report with PADS data if the product is operating in restricted mode. If a `NEWLIST TYPE=REPORT_STC` is not present before the REPORT command then a single-complex default layout is included, CARLa member `CKRRSTC`. See "Report layouts" on page 252.

SENSITIVE
SENS

Reports on all data set profiles, `GLOBAL DATASET` members, and missing the High-level qualifier (HLQ) generics that cover sensitive data sets that require protection. HLQ generics are of the form *user.*** or *group.***. The data sets being considered sensitive are included underneath each profile listed..

Table 305 lists the sensitive data sets by access level.

Table 305. Sensitive data sets for each access level

Access Level	Sensitive data sets
READ	RACF data sets RRSF data sets SMF recording data sets page data sets swap data sets JES2/JES3 checkpoint JES2/JES3 spool space JES2/JES3 parameter data sets system dump data sets TSO user attribute data set UADS

Table 305. Sensitive data sets for each access level (continued)

Access Level	Sensitive data sets
UPDATE	APF data sets LPA data sets SYS1.LPALIB SYS1.NUCLEUS JES2/JES3 STC and TSU procedure libraries MSTR parameter libraries MSTR procedure libraries MSTR VIO index STGINDEX HFS data sets (UNIX file systems) HSM control data sets MCDS, BCDS, OCDS DMS control data set DMSFILES DMS authorized parameter libraries DMS default parameter library CA1 tape management catalog TMC SMS ACDS, COMMDS, and SCDS data sets IODF data sets RMM parameter library and control data sets TLMS volume master file VMF ABR archive control file ACF
ALTER	ICF catalogs

If a `NEWLIST TYPE=REPORT_SENSITIVE` is not present before the REPORT command then a single-complex default layout is included, CARLa member `CKRRSENS`. See "Report layouts" on page 252.

Report data sort order

The output sort order can be given with the BY keyword. This setting only orders the default report layout. If you specify your own `NEWLIST TYPE=REPORT_`*`report`* statement, this keyword only defines the content of the field ORDER.

BY= *list*

Keywords indicating report sort order. *list* is a list enclosed in parentheses with the keywords separated by commas indicating one or more of the following sort fields. (The order given is the default sort order.)

ID

User or group to which data set belongs (but module name with REPORT AC1).

KEY DSN DATASET

Data set name (resource name).

MEMBER MEM

Member name (with AC1 PADS, and STC).

REASON

Reason (usable with NONDEFAULT and NONREDUNDANT).

Page headers

Use the PAGEBY keyword to provide page headers for reports. The BY keyword must precede the PAGEBY keyword. The BY keyword applies directly to the default report layout. If you specify your own `NEWLIST TYPE=REPORT_`*report* statement, this keyword only defines the content of the field PAGEBY.

PAGEBY= *key*

Keywords indicating report page separation. The *key* specified must be the first one in the `BY=` list. The *key* is one of the following fields.

ID
User or group to which data set belongs.

KEY DSN DATASET
Data set name (resource name).

MEMBER MEM
Member name (with AC1 PADS, and STC).

REASON
Reason (usable with NONDEFAULT and NONREDUNDANT).

Using the REPORT command

You can use the REPORT command to produce many different types of reports depending on the parameters you specify. The following examples provide a starting point for creating reports.

- "Example - Reporting by scope"
- "Example - Reporting by multiple scopes"
- "Example - Customizing the report scope"
- "Example - Reporting on sensitive data set protection"
- "Example - Reporting on nondefault profiles" on page 884
- "Example - Reporting on contents of selected profiles" on page 884

Example - Reporting by scope

This example shows how to request a report of all profiles that can be updated by anybody. It also requests a list of the data sets covered by each data set profile.

```
report scope=*, access=update, datasets
```

Example - Reporting by multiple scopes

This example shows how to request a number of scope reports, each starting on a new page. The PAGEBY parameter is required to show the user ID that is being reported on in the page headers).

```
report scope=user1, scope=user2, pageby=id
```

Example - Customizing the report scope

```
newlist type=report_scope,
toptitle='S C O P E   R E P O R T  -  A C C E S S: ',
st='Sorted on access, id, key and class'
 exclude access<=read
 sortlist access(page,toptitle) stamp(toptitle),
         id key(nondispl),
         class proftype key('Profile name' 44) volser,
         access via when

report scope=sysprog, scope=stgadmin
```

Example - Reporting on sensitive data set protection

This example requests a report on the protection of sensitive data sets. Note that the DATASET parameter must not be specified if you want to see only the sensitive data sets, and not all data sets covered by the profile also covering a sensitive data set.

```
report sensitive
```

Example - Reporting on nondefault profiles

This example shows how to report non-default profiles in a way suitable for distribution to RACF group owners. This is accomplished by requesting page separators for each identity (first qualifier). The page header changes when the PAGEBY value changes.

```
report nondefault, pageby=id
```

Example - Reporting on contents of selected profiles

This example requests a quick report on the contents of selected profiles.

```
select class=facility
report profiles
```

SELECT and EXCLUDE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

The SELECT and EXCLUDE commands share the same parameters.

- The SELECT command selects records that match the conditions specified.
- The EXCLUDE command narrows the selection results by removing or omitting records that match the criteria in the EXCLUDE statement.

For example, you can use a SELECT statement to select all records in a particular resource class, the DATASET class for example. Then, you can use an EXCLUDE statement to remove DATASET profiles that do not have a profile name that matches a specified name pattern.

The SELECT command can be abbreviated as SEL or S. The EXCLUDE command can be abbreviated as EXCL or X.

The following example shows the basic syntax for SELECT and EXCLUDE statements.

```
select field=value [ field2=value2 ... ] [ field3==field4 ...]
select field5=value5
exclude field6=value6
```

Scope of SELECT and EXCLUDE command - global and local

The *scope* and *type* of a SELECT and EXCLUDE command depends on the context in which it is specified. Commands specified outside the domain of a NEWLIST statement have a global scope. Commands within the domain of a NEWLIST statement have a local scope.

Global scope - specified outside the domain of a NEWLIST

SELECT and EXCLUDE statements outside the domain of a NEWLIST statement have a global scope. These selections always apply to RACF profiles (RACF NEWLIST type). Any record not selected by global SELECT and EXCLUDE processing is invisible to the rest of zSecure Admin and Audit. Therefore, this selection not only restricts the input of all RACF NEWLIST statements, but also applies to intrinsically global commands like VERIFY, REPORT, COPY, MOVE, REMOVE, and MERGE. The selection also applies to NEWLIST commands that can be scoped like UNLOAD, SORTLIST and DISPLAY.

You can use a global EXCLUDE, specified with SETUP PREAMBLE for example, to determine the impact of removing profile(s) from the database. This type of EXCLUDE statement can circumvent structural errors or other unsupported conditions in the RACF database. See “SE.3 Setup - Preamble” on page 1654.

Usage notes

- Lookup operations and global commands like VERIFY might require more profile types as input than might be immediately obvious. Refer to the documentation for the global commands for details.
- For lookups, do not forget to include the profiles and segments being looked up.
- In restricted mode, only the QUAL= parameter can be used for global SELECT and EXCLUDE processing.

Local scope - specified within the domain of a NEWLIST

A SELECT or EXCLUDE inside the domain of a NEWLIST statement has local scope. Its type depends on the NEWLIST type. The default type is RACF. A local SELECT or EXCLUDE statement affects only the commands within the NEWLIST statement. Subsequent NEWLIST statements are not affected unless they are linked by PROFLIST, NOTPROFLIST, or LIKELIST statements.

Selection types

A SELECT or EXCLUDE statement evaluates a field or fields based on specified test criteria. The following types of tests can be used.

- "Selecting with a *field-value* compare"
- "Selecting with a *field-field* compare"
- "Selecting on field existence" on page 886
- "Selecting on manipulated fields" on page 887
- "Selecting based on previously specified criteria (LIKELIST)" on page 887

Selecting with a *field-value* compare

A *field-value* comparison selects or excludes records based on whether the value of the specified field matches the literal or constant value specified in the statement. This comparison type evaluates a field on the left of the relational operator against a constant value on the right of the relational operator, field=value for example.

Table 306 lists the different ways to specify search criteria for a field-value comparison. The operations available depend on the field and the values specified.

Table 306. Field-value selection - Relational operators, substring scan, and pattern matching

Operation	Valid in ...
= (equality)	all fields
<> or ¬= (inequality)	most fields
> , < , <= , and >= (greater than, less than, or equal to)	most text, numerical, date, and access level fields
: (substring scan)	most text fields *fieldname* =:*value*
filter (pattern matching)	most text fields

Selecting with a *field-field* compare

A *field-field* comparison selects or excludes records based on whether the contents of a field matches the contents of another field. For example, you might want to select all records that have a matching user ID owner and user ID default group. This comparison type compares the contents of a field on the left of a relational operator to the contents of a field on the right of the relational operator, field1==field2 for example. The relational operator,== in this example, is doubled

to differentiate a *field-value* compare from a *field-field* compare. In order to match, the field contents must have the same length and the same value.

Table 307 lists the relational operators for field-field comparisons.

Table 307. Field-field compare - relational operators

Normal operator	Field-compare operator
=	==
<>, ¬=	<<>>, ¬== **Note:** The ¬ is not doubled.
<	<<
>	>>
>=	>>==
<=	<<==

Usage notes Field compare operations are subject to the following restrictions.

- For character fields, the field contents is compared excluding trailing spaces.
- Substring operations and field lookups can be used on both sides of the doubled relational operator.
  - Both fields must have the same format, two character fields for example. Only the character, numerical, hexadecimal, and date formats are supported.
  - At most one of the fields can be repeated. That is, you cannot compare two (potentially) repeated fields.
  - The maximum field length is 255 characters.
  - You cannot use the substring scan operator (`=:`) because it is not supported.
-

Field-field comparison examples: The following example selects all RACF user profiles with a default-group not equal to the owner.

```
newlist type=racf
select class=user dfltgrp<<>>owner
sortlist key(8) dfltgrp owner pgmrname
```

The following example selects all SMF records for which the default group of the user is not equal to the user's owner.

```
newlist type=smf
select user:dfltgrp<<>>user:owner
sortlist user user:dfltgrp user:owner recorddesc
```

The following example selects all SMF records for which the first part of user's default group is not equal to the user's owner.

```
newlist type=smf
select substring(user:dfltgrp,1,4)<<>>substring(user:owner,1,4)
sortlist user user:dfltgrp user:owner recorddesc
```

Selecting on field existence

You can test field existence using the `EXISTS` and `MISSING` operations. These keywords can be specified in the following formats.

- `MISSING`(*field*)
- `EXISTS`(*field*)

Selecting on manipulated fields

In both *field-value* selection and *field-field* selection, you can change the contents of the fields in the compare statement before processing the comparison operation. The functions available for changing the contents are fully described in "Field value manipulation" on page 760. The following restrictions apply when you use indirect references in a SELECT statement.

1. In a NEWLIST TYPE=RACF context, no indirect references can be used.
2. Indirect references to a TYPE=*deftype* can only be used in a SMF NEWLIST context.

Selecting based on previously specified criteria (LIKELIST)

You can refer to the effective selection made in a NEWLIST statement in a later NEWLIST statement of the same type. When you define the first NEWLIST statement, specify a name for the statement using the NAME=*name* parameter. Then, you can refer to the statement by adding a LIKELIST=*name* clause on the second NEWLIST.

In the following example, this SELECT statement uses the selection criteria on the referenced NEWLIST to select the same records from the NEWLIST where the clause was added.

```
SELECT LIKELIST=name
```

You can use the LIKELIST function to configure the selection criteria for a number of queries in one place.

You can also use the LIKELIST function to restrict the domain of an overall report that includes multiple queries. For each NEWLIST you add the clause to the basic selection on each SELECT statement. For example, adding the following statement to a CARLa query selects all records with type 80 but restricts the effective selection to within the set defined in NEWLIST NAME=*name*.

```
SELECT TYPE=80 LIKELIST=name
```

Sometimes it makes sense to put such a concatenation in one place–in an SCKRCARL member for example– and make the NEWLIST selection statement configurable. That is, have the NEWLIST selection statement generated dynamically by the interface.

For example, several SMF CARLa scripts refer to a NEWLIST named *SMFSEL*, which is not included in the scripts. A dummy selection statement, NEWLIST NAME=SMFSEL is provided in CARLa script CKALFSEL. This script can be run by adding the following code either as is or with a modified CKALFSEL member. The first INCLUDE can also be replaced with a NEWLIST named *SMFSEL* that makes the desired selections.

```
INCLUDE MEMBER=CKALFSEL
INCLUDE MEMBER=actual report member
```

If you run such a configurable report without supplying a preceding, appropriately named NEWLIST selection statement, a CKR0403 syntax error occurs. Instead of adding the NEWLIST statement, you can also add a SUPPRESS MSG=403 command. In that case, the selection is regarded as void. That is, the LIKELIST clause selects all records just as the absence of a SELECT statement causes all records to be selected.

The following statement selects all records not covered in another query.

```
EXCLUDE LIKELIST=name
```

This type of statement can be useful to format specific records in one way and the rest of the records in another (standard) way.

The LISTLIKE keyword is an alias for LIKELIST.

Evaluating SELECT and EXCLUDE statement criteria

Each statement can include multiple test criteria. Test criteria are specified and processed based on the following implicit and explicit syntax rules.

- If several tests are specified in succession, a logical AND is implied. You can also specify explicitAND, OR, and NOT operators.
- Use parentheses to clarify and define the logical relation between AND and OR clauses.
- Parentheses are required with the NOT operator.
- If parentheses are not used, the effect of multiple explicit AND and OR operators is dependent on the NEWLIST type. TYPE=RACF is right-associative, which means that A and B or C must be read as A and (B or C). All other NEWLIST types are left-associative which means that A B or C must be read as (A B) or C.
- Use parentheses whenever there is ambiguity about which clause has priority.
- Implicit AND operators have a higher precedence than explicit AND and OR operators.
- Clauses on SELECT and EXCLUDE statements can be separated by blanks or commas.
- If a statement is to continue on the next line, end the line with a comma.

Processing multiple SELECT and EXCLUDE statements

Multiple SELECT and EXCLUDE statements can be specified in any context. Multiple statements are interpreted based on the following processing rules.

- All SELECT statements in any context are combined with a logical OR.
- All EXCLUDE statements in any context are combined with a logical OR.
- The SELECT statements are processed first. Records that match the selection criteria are included in the selection results.
- The records in the selection results are then processed based on the EXCLUDE statements. Any selected record that matches the criteria in an EXCLUDE statement is removed from the selection results. If no EXCLUDE statements are present, all selected records remain in the selection results.

The overall result is that, in any context, a record is selected if it matches the criteria in *any* SELECT statement and does **not** match the criteria in *any* EXCLUDE statement.

Valid fields for SELECT and EXCLUDE statements

The valid *fields* for SELECT and EXCLUDE statements depend on the type of information to be reported as specified by the NEWLIST parameter in SELECT or LIST statements. For NEWLIST TYPE=RACF statements, the valid fields depend on the RACF templates. In addition to the fields in the templates, a number of built-in fields and aliases are also valid. The valid fields for the RACF NEWLIST statement are described in "SELECT and EXCLUDE for NEWLIST TYPE=RACF" on page 889. For all other NEWLIST types, the fields that can be used are predefined.

Most fields can be used both for SELECT and EXCLUDE processing and for output. Some fields can only be used for selection or output. For an overview of the available fields for each report type, see Chapter 13, "SELECT/LIST Fields," on page 953.

Warning: Using selection criteria for different fields in the same repeat group might produce unexpected output. The unexpected results occur because the values for the fields in the selection criteria might have been found in different repeat group entries, and there might not be a single repeat group entry that has the combination of fields. For the ACL, CUSTOM_DATA, and USR repeat groups in the RACF NEWLIST (NEWLIST TYPE=RACF), you can use the ACL, CUSTOM_DATA, and USR selection parameters. See "SELECT/EXCLUDE ACL(...)" on page 890, "SELECT/EXCLUDE CUSTOM_DATA(...)" on page 890, and "SELECT USR(...)" on page 892. For other repeat groups, there is no simple way to select or exclude records based on different fields in the same repeat group entry.

You can use the DEFINE SUBSELECT command to include selected repeat group entries for some field types in display panels and reports. For more information, see "DEFINE" on page 750.

SELECT and EXCLUDE for NEWLIST TYPE=RACF

The fields you can specify as selection criteria for the RACF NEWLIST type are defined in the RACF templates. See "RACF: RACF profiles" on page 1124. You can also specify special, predefined fields to customize the SELECT and EXCLUDE statements for RACF profiles. For details, see the following sections.

- "Selecting by profile property"
- "Searching by profile name" on page 890
- "Searching by value in a specific field" on page 892
- "Selecting by built-in alias names" on page 893
- "Selecting profiles by resource class" on page 894

Selecting by profile property: Use the following parameters in NEWLIST TYPE=RACF statements to specify values for profile properties.

SEGMENT= *segment*
SEG=*segment*
S=*segmentpredefseg*
NO*predefseg*

Selects profiles that contain the indicated segment types. Only the segment is present in the selected record. A number of predefined segments can also be selected by specifying only the segment name. These predefined segments are: CICS, CDTINFO, CERTDATA, DCE, DFP, DLFDATA, EIM, KERB, LANGUAGE, LNOTES, NETVIEW, NDS, OMVS, OPERPARM, OVM, PROXY, SESSION, SIGVER, STDATA, SVFMR, TME, TSO, or WORKATTR.Prefixing the segment name with NO selects those profile segments that do not match the indicated segment. Selection on the absence of a segment is not supported.

SCAN=*val*
SCAN=(*val, val,...***)**

A string to scan for or a list of strings to scan for. The entire profile is scanned, unless the FIELD= parameter is also specified. If you use the FIELD= parameter, it must be specified before the SCAN= parameter. The SCAN= parameter is a fast way to restrict operations to certain profiles. If more SCAN parameters are coded on one SELECT or EXCLUDE clause or if a list of values is enclosed in parentheses, the scan matches if any of the SCAN values matches.

The following syntax rules apply to specifying values in the SCAN= clause.

- Use single, double or left quotations around the value if it contains lowercase, blanks, commas, or other special characters.
- A quoted string can be followed by a string conversion character C or T.
- The String conversion character C indicates case-sensitive. The string conversion character T indicates not case-sensitive.
- In a list of values, case-sensitive and not case-sensitive can be mixed.

Notes:

1. Hexadecimal string conversion is not supported.
2. The SCAN= parameter has been functionally replaced by the substring scan specification.

   fieldname =:*value*.

DB= *number*
Selects profiles based on the sequence number of the RACF database that originally contained them. The sequence number is defined in the RACF database name table.

RBA= *hex*
Selects profiles based on the Relative Byte Address value from the originating database. Together with the DB= parameter, this value describes exactly one profile. Its main use is to select profiles in situations where BAM conflicts are reported by IRRUT200, by excluding profiles that are in use but not present in the index for example.

Searching by profile name: The following parameters can be used for selections based on the profile name. They are mutually exclusive within a single SELECT/EXCLUDE clause.

ACL(*limitedACLsubselectclause***)**
Select on a combination of values in a single ACL repeat group entry. For the syntax of a 'subselect clause' and the fields generally supported in one, refer to “DEFINE” on page 750. The ACL subselect fields USER and GROUP are not supported for SELECT and EXCLUDE--use ID instead (when the id is encountered on the access list, the user or group profile it is to be matched against might not have been read yet, so the type is generally unknown).

BESTMATCH=*name*
Select the best matching profile as found with MATCH. This parameter performs the same function as the MATCH parameter but only shows the best matching profile(s). This is the profile that would end up on top if the result of a MATCH would have been sorted on SEARCHKEY. There are a few restrictions concerning the usage of BESTMATCH. This parameter can not be used in combination with the PROFILE / KEY, MASK / FILTER or MATCH parameter, can not be used in an explicit nor an implicit OR (multiple select statements), can not be used as a target for a LIKELIST, and can not be used for exclusion. BESTMATCH does not necessarily always result in one profile. All profiles that are equally 'best' will be shown.

CUSTOM_DATA(CUSTOM_DATA*subselectclause***)**
Select on the combination of key, type, and value in a single custom field entry. For the syntax of the CUSTOM_DATA*subselectclause* and the fields supported in one, see “DEFINE” on page 750.

MASK= *mask*
FILTER=*mask*
A mask for the profile key. Use **%**, *, and **.**** (enhanced generic naming). The

filter is *always* interpreted as enhanced generic, independent of the RACF database setting for EGN. If you specify a generic profile key here, this value matches generic and discrete profiles that are covered by this name. The meaning of a single * depends on the entity type.

- For data sets, a single * matches a qualifier with a maximum of 8 characters.
- For general resource profiles, a single * at the end of a FILTER or MASK statement, selects only a single qualifier (while in RACF it means any number of profiles).

The mask value can be specified with or without quotation marks. If no quotation marks are specified, the match processing is not case sensitive. If single, double or back quotation marks are specified, the match processing is case sensitive.

There is one extension to EGN matching. A single asterisk can also be used to match the first part of a qualifier. For example, **.*ABC.** finds qualifiers ending in ABC anywhere in the field, except for the first qualifier.

MATCH= *name*

Select all profiles that match the specified resource name. The result includes both discrete and generic profiles. However, the indicated bit and the volume serial numbers are ignored. The MATCH keyword is useful to determine the profiles that protect a resource if another profile is deleted. For grouping profiles, the match is on the member list of the grouping profile.

The following syntax rules apply to the MATCH specification.

- For case-senstive matching, specify the *name* in quotation marks (single, double, or backward). If case is not significant, specify the *name* without quotation marks.
- If a keyword is specified for a member class, the grouping class is automatically included. This syntax allows selection of all profiles that can protect a CICS transaction. See "Examples - SELECT and EXCLUDE statements" on page 908.
- If the MATCH and keywords are specified together, make them the first keywords in the SELECT or EXCLUDE statement or the WHERE clause.
- Specify the SEARCHKEY output field to sort the resulting profile names in order of best match.

PROFILE= *name*
PROFILE=(*name*, *name*, **...)**
KEY=*name*
KEY=(*name*, *name***)**

Selects a specific profile name. If you specify generic characters, the profile searched has exactly the key specified. Unlike other fields where generic characters imply a pattern match, generic characters for the KEY field are treated literally. To match more than one profile, you must use one of the following key words: MASK, FILTER, MATCH, or BESTMATCH. Use quotation marks (double or left) around the profile name, if it contains lowercase, blanks, commas, or other special characters (like /*). Names specified without quotation marks are converted to uppercase and only match uppercase profiles. Names specified in quotation marks or a list of names, even when the list consists of only one name, are interpreted to be of type T for text. The comparison of these values is not case sensitive. If you want the comparison to be case sensitive, specify the *name* as type C, *name*C for example.

USR(*USRsubselectclause***)**
Select on a combination of values in a single USR repeat group entry. For the syntax of a subselect clause and its supported fields, see "DEFINE" on page 750.

Searching by value in a specific field: Use the following parameters to search for values in a specific field.

*fieldname***=***vall*
*fieldname***<***vall*
*fieldname***>>***vall*
*fieldname***<=***vall*
fieldname **>=vall**
*fieldname***<>***vall*
*fieldname***(***vals***)**
Specifies a field name to be searched for in the profile. All normal comparison operators are supported. In addition, the format specifying a list directly following *fieldname* is equivalent to specify an equal sign.

fieldname
Specifies a name defined in a template, in a built-in alias, or by the keyword FIELDVALUE to indicate that the field name is given by the FIELD parameter. See "Alias names local to segments" on page 894.

vall
Specifies a value to search for in the specified field. Values can be specified using a pattern, a substring scan, or a list of values.

- To specify a pattern, use % or * in the search string.
- To specify a *substring scan*, start the string with the substring scan operator (:) that represents the SCAN operand. See "Selecting by profile property" on page 889 for more information about the SCAN parameter.
- To specify a list of values, separate each value with a comma and enclose the list in parentheses.

vals
Specifies a *value* to search for in the field specified, or a *list of values* separated by commas.

Usage notes:

1. A *pattern*, *substring scan*, or *value list* is only valid for equality and inequality comparisons and means that the field contains any of the values in the list, or the field contains none of the values in the list, respectively.
2. Values can be enclosed in *single, double, or left quotations*. Quotations are **only** required for values that contain a lowercase character, blank, comma, parenthesis, colon, semicolon, a pattern character (% or *) not intended to be the start of a pattern search, or comment character pairs (/* or */).
3. Unquoted strings are converted to uppercase.
4. Quoted strings can suffixed with one of the following *type* characters listed in Table 308. The type determines how the value is to be used.

Table 308. Valid types for quoted string values

Conversion Type	Description
X	Use as a hexadecimal number
B	Use as a bit mask
C	Use as an exact character value

Table 308. Valid types for quoted string values (continued)

Conversion Type	Description
T	Use as a character string in a case-insensitive compare.
G	Use as a pattern in a case-insensitive compare.

5. Quoted character strings that do not specify a *type* and unquoted strings that do not contain any generic symbols are interpreted as type `T`.
6. If the string does not contain any generic symbols or specify any type, it is considered to type `T`.
7. If the string contains generic symbols and is used on a substring scan, it is considered to be type `T`. Otherwise, it is considered type `G`.
8. If a substring scan is used, only types `C` and `T` are supported.
9. If you specify a bit mask value, each bit must be represented by one of the following values: *`0`*, *`1`*, or **`.`** where **`.`** denotes don't care.
10. Conversion to internal format is supported for the following field types.
    - flag (*`YES/NO/ON/OFF`*)
    - binary and hex
    - date
    - access, authority, audit access, audit
    - text

    See "SELECT and EXCLUDE for NEWLIST types other than TYPE=RACF" on page 900 for information about these field types.
11. You can view the type that zSecure assumes for a field by issuing the `SHOW TEMPLATES` command.
12. The formats accepted are like the display format detailed in the "Controlling report and display output for LIST family commands" on page 795, except for the date format. The supported format for date values can be found in "Date fields" on page 903.

segment(*fieldtests***)** *segment*
A number of the *field-value* and *field-field* tests described in "Selection types" on page 885 can be used to select on the following segment names: `CDTINFO`, `CERTDATA`, `CICS`, `DCE`, `DLFDATA`, `DFP`, `EIM`, `KERB`, `LANGUAGE`, `LNOTES`, `NDS`, `NETVIEW`, `OMVS`, `OVM`, `OPERPARM`, `PROXY`, `SESSION`, `SIGVER`, `STDATA`, `SVFMR`, `TME`, `TSO` or `WORKATTR`. The select or exclude criteria must be enclosed in parentheses.The segment name can also be specified by itself to select the specified segment. (See "Examples - SELECT and EXCLUDE statements" on page 908.)

FIELD= *fieldname*
Specifies a field name to be searched for in the profile. Must be used in conjunction with the field name `FIELDVALUE=` or the keyword `SCAN=`, as explained in "Searching by value in a specific field" on page 892 and "Selecting by profile property" on page 889. The field name must be one defined in a template or the word `KEY` to scan the internal profile key (without any class prefix). This parameter is intended for use when the field name is the same as one of the other `SELECT` parameters, or to limit a `SCAN` operation to a specific field.

Selecting by built-in alias names: The following tables lists the built-in alias names that can be used when specifying search criteria.

- "Alias names local to segments" on page 894

- "Alias names for LANGUAGE and SESSION names"
- "Aliases not within a segment"

Alias names local to segments: Table 309 lists the built-in alias names local to segments. These alias names are intended to provide similarity to the RACF commands. These names are only valid in the scope of the corresponding segment selection *segment(...)*.

Table 309. Built-in alias names local to segments

TSO(name())	alias for	OPERPARM(name))	alias for
ACCTNUM	TACCNT	ALTGRP	OPERALTG
DEST	TDEST	AUTH	OPERAUTH
HOLDCLASS	THCLASS	CMDSYS	OPERCMDS
JOBCLASS	TJCLAS	KEY	OPERKEY
MAXSIZE	TMSIZE	LEVEL	OPERLVL
MSGCLASS	TMCLASS	MFORM	OPERMFRM
PROC	TLPROC	MONITOR	OPERMON
SECLABEL	TSOSLABL	MSCOPE	OPERMSCP
SIZE	TLSIZE	ROUTCODE	OPERROUT
SYSOUTCLASS	TSCLASS	STORAGE	OPERSTOR
UNIT	TUNIT		
USERDATA	TUDATA		

Alias names for LANGUAGE and SESSION names: Table 310 lists the built-in alias names that can be used for LANGUAGE and SESSION names.

Table 310. Alias names for LANGUAGE and SESSION

LANGUAGE(*name***())**	alias for	**SESSION(***name***())**	alias for
PRIMARY	USERNL1	INTERVAL	KEYINTVL
PRIM	USERNL1		
SECONDARY	USERNL2		
SEC	USERNL2		

Aliases not within a segment: The following table lists built-in alias names not within a segment.

Table 311. Built-in alias names not within a segment

	alias for
DATA	INSTDATA
UNIT	DEVTYPX
VOL	VOLSER
VOLUME	VOLSER

Selecting profiles by resource class: You can also select and exclude profiles by resource class. The parameters, fields and attributes that can be used for selection criteria depend on the resource class type. See the following topics for details.

- "Fields valid for all resource classes" on page 895

- "Fields valid for the DATASET class" on page 896
- "Fields valid for the USER class" on page 896
- "Fields valid for the GROUP class" on page 899
- "Fields valid for the TAPEVOL class" on page 899

Fields valid for all resource classes: You can use the following parameters and fields to select profiles from any resource class.

CLASS= *class*
CL=*class*
C=*class*
CLASS=(*class***,...)**
The RACF class (USER, GROUP, DATASET, CONNECT, PROGRAM, ACCTNUM, GCICSTRN, ...). The special value GENERAL indicates all kinds of general resource classes. If used with the MATCH or BESTMATCH keywords, the class selection has a special meaning, selecting both a member class and the grouping class. For selection, all normal relational operators and value types, value list and filter specification is supported for example. For more information, see the general "Searching by value in a specific field" on page 892 description.

DISCRETE
Selects discrete profiles.

GENERIC
Selects generic profiles.

HEXKEY= *value*
The profile key in internal, not human-readable format. This value can be used to search for profiles with specific internal values or having specific generic characters.

MEMBERCLASS= *class*
For grouping profiles, this field contains the name of the corresponding member class. For member profiles, this field contains the name of the normal profile class. For all other profile types, this field is undefined.

MEMBERKEY= *key*
For grouping profiles, this repeated field contains the profile keys of all members. For member profiles, this field contains the 'normal' profile key. For all other profile types, this field is undefined.

NOCATEGORY
Select all profiles that do not have a CATEGORY defined.

NODATA
Select all profiles without INSTDATA.

NOSECLABEL
Select all profiles that do not have a SECLABEL defined.

NOSECLEVEL
Select all profiles that do not have a SECLEVEL defined.

NOWARNING
NOWARN
Selects profiles with the warning indicator off.

QUAL= *id*
Q=*id*
The QUAL field matches the first qualifier for data set and general resource profiles, and contains the profile key for user and group profiles. For data set

profiles, *id* matches the first qualifier as changed by ICHCNX00. For selection, all normal relational operators and value types can be used, see the general *fieldname* description.

WARNING
WARN
Selects profiles with the warning indicator on.

Fields valid for the DATASET class: You can use the following attributes to select profiles from the DATASET class.

PADS
Selects DATASET profiles with a non-empty conditional access list as well as profiles in the PROGRAM class.

VSAM
Select DATASET profiles with the VSAM indicator.

NONVSAM
Select non-VSAM data set profiles.

MODEL
Select DATASET profiles with the MODEL indicator on.

NOMODEL
Select DATASET profiles with the MODEL indicator off.

TAPEDSN
Select DATASET profiles with DSTYPE=TAPE.

NOTAPEDSN
NOTAPE
Select DATASET profiles without DSTYPE=TAPE.

GROUPDS
GROUPDSN
Select DATASET profiles with group-data set indicator on.

USERDS
USERDSN
Select DATASET profiles with the user-data set indicator on.

ERASE
Select DATASET profiles with the erase-on-scratch flag on. This is independent of the global ERASE setting.

NOERASE
Select (data set) profiles with the erase-on-scratch flag off. This is independent of the global ERASE setting.

Fields valid for the USER class: You can use the following attributes to select profiles in the USER class.

UAUDIT
Select user profiles that have user-level auditing active.

NOUAUDIT
Select user profiles that have no user-level auditing active.

PASSWORD
Select user profiles that have a password.

NOPASSWORD
Select user profiles that do not have a password.

OIDCARD
OID
Select user profiles that have an OID card key.

NOOIDCARD
NOOID
Select user profiles that do not have an OID card key.

GRPSPEC
GROUPSPECIAL
GROUPSPEC
GROUPSP
GRPSP
GRPSPECIAL
Select USER profiles that contain a group-special connect.

NOGRPSPEC
NOGROUPSPECIAL
NOGROUPSPEC
NOGROUPSP
NOGRPSP
NOGRPSPECIAL
Select USER profiles that contain one or more connect entries without group-SPECIAL. To select a profile without *any* group-SPECIAL connect, use NOT(GRPSPEC).

GRPOPER
GROUPOPERATIONS
GROUPOPER
GROUPOP
GRPOP
GRPOPERATIONS
Select USER profiles that contain a group-OPERATIONS connect.

NOGRPOPER
NOGROUPOPERATIONS
NOGROUPOPER
NOGRPOP
NOGROUPOP
NOGRPOPERATIONS
Select USER profiles that contain one or more connect entries without group-OPERATIONS. To select a profile without *any* group-OPERATIONS connect, use NOT(GRPOPER).

GRPAUD
GROUPAUDITOR
GROUPAUDIT
GROUPAUD
GRPAUDITOR, GRPAUDIT
Select USER profiles that contain a group-AUDITOR connect.

NOGRPAUD
NOGROUPAUDITOR
NOGROUPAUDIT
NOGROUPAUD
NOGRPAUDITOR, NOGRPAUDIT
Select USER profiles that contain one or more connect entries without group-AUDITOR. To select a profile without *any* group-AUDITOR connect, use NOT(GRPAUD).

GRPGRPACC
GROUPGRPACC
Select USER profiles that contain a connect with the GRPACC attribute.

NOGRPGRPACC
NOGROUPGRPACC
Select USER profiles that contain a connect with the NOGRPACC attribute.

GRPREVOKE
GROUPREVOKE
Select profiles that contain a connect with the REVOKE attribute or that were revoked by date and not yet resumed at the day the RACF unload was made (the DUMPDATE). This selects USER profiles with at least one revoked connect.

NOGRPREVOKE
NOGROUPREVOKE
Select profiles that contain a connect without the REVOKE attribute and not yet revoked by date or where the day the RACF unload was made is past the resume date. This selects USER profiles with at least one non-revoked connect.

GRPADSP
GROUPADSP
Select USER profiles that contain a connect with the ADSP attribute.

NOGRPADSP
NOGROUPADSP
Select USER profiles that contain a connect without the ADSP attribute.

NOCLAUTH
Select all USER profiles that do not have any CLAUTH authority.

PWHASHED
HASHEDPW
Select all USER profiles that have a password that is hashed, not encrypted.

PROTECTED
Select all USER profiles that have the PROTECTED (no password, and cannot be logged on with) attribute.

NOPROTECTED
Select all USER profiles that do not have the PROTECTED attribute.

RESTRICTED
Select all USER profiles that have the RESTRICTED (are not granted access through UACC, ID(*) or GAT) attribute.

NORESTRICTED
Select all USER profiles that do not have the RESTRICTED attribute.

SPECIAL
SPEC
Select profiles with the SPECIAL attribute.

NOSPECIAL
NOSPEC
Select profiles without the SPECIAL attribute.

OPERATIONS
OPER
Select profiles with the OPERATIONS attribute.

NOOPERATIONS
NOOPER
Select profiles without the OPERATIONS attribute.

AUDITOR
Select profiles with the AUDITOR attribute.

NOAUDITOR
Select profiles without the AUDITOR attribute.

REVOKE
REVOKED
Select profiles with REVOKE attribute. In addition, the date of the RACF data set unload is used to select profiles that are revoked by date based on the revoke date and resume date fields.

NOREVOKE
NONREVOKED
NOTREVOKED
Select profiles without the REVOKE attribute. In addition, the date of the RACF data set unload is used to verify that profiles are not revoked by date based on the revoke date and resume date fields.

ADSP
Select profiles with the ADSP (automatic data set protection) attribute.

NOADSP
Select profiles with the NOADSP attribute.

GRPACC
Select profiles with the GRPACC (group access) attribute.

NOGRPACC
Select profiles without the GRPACC attribute.

Fields valid for the GROUP class: You can use the following attributes to select profiles in the GROUP class.

NOTERMUACC
NOTERMUACC
Select profiles with the NOTERMUACC (no terminal access based on UACC) attribute.

TERMUACC
Select profiles without the NOTERMUACC attribute.

NOUNIVERSAL
Select profiles with the NOUNIVERSAL (limited amount of connects) attribute.

UNIVERSAL
Select profiles with the UNIVERSAL (unlimited amount of default connects) attribute.

Fields valid for the TAPEVOL class: You can use the following attributes to select profiles in the TAPEVOL class.

SINGLEDS
Selects (tape volume) profiles with the single-data set indicator on.

NOSINGLEDS
Selects (tape volume) profiles with the single-data set indicator off.

AUTOTAPE
AUTO
Select automatic TAPEVOL profiles.

NOAUTOTAPE
NOAUTO
NONAUTO
NOTAUTO
NONAUTOTAPE
NOTAUTOTAPE
Select non-automatic TAPEVOL profiles.

TVTOC
Select TAPEVOL profiles with a TVTOC.

NOTVTOC
Select TAPEVOL profiles without a TVTOC.

SELECT and EXCLUDE for NEWLIST types other than TYPE=RACF

This section describes standard fields that can be used to specify search criteria on SELECT and EXCLUDE statements for NEWLIST types other than TYPE=RACF. These fields can also be used for the NEWLIST subselections specified with the DEFINE command.

For information about the specific fields that can be used with each NEWLIST type, see Chapter 13, "SELECT/LIST Fields," on page 953. For information about selection and exclusion fields for RACF profiles (NEWLIST TYPE=RACF), see "SELECT and EXCLUDE for NEWLIST TYPE=RACF" on page 889.

The field types available with these NEWLIST types and with subselection can be separated into 8 different types, each treated differently.

Table 312. SELECT and EXCLUDE field types for NEWLIST types other than TYPE=RACF

Selection field type	Description
"Character fields" on page 901	These support pattern searches, substring selection, and string conversions.
"Numerical fields" on page 902 (Decimal and hexadecimal)	These fields support numerical conversions.
"Bitfields/Boolean values" on page 902	These fields support ON/OFF or YES/NO selection, as well as specification of bit masks.
"Date fields" on page 903	These fields support dates entered in ISO-format (e.g. 2002-02-02), European format (e.g. 02Feb2002), Julian date format (e.g. 2002/274), TODAY, and NEVER.
"Time fields" on page 904	
"Combined date and time fields" on page 904	Combine any valid date and time format. Enclose each parameter specification in quotations. Separate time and date values with a space.
"Access levels" on page 905	These fields support selection of a single access level or a list of access levels, as well as access higher or lower than the level specified.
Group authority level fields (See "Access levels" on page 905.)	These fields support selection of a single group authority or a list of group authority levels, as well as authority higher or lower than the level specified.
"Matching masks" on page 905	The special keyword MATCH can be used to match a mask field with a specific value.
"UNIX fields" on page 905	These fields allow selection based on file attributes, extended attributes and audit flag settings.

Table 312. SELECT and EXCLUDE field types for NEWLIST types other than TYPE=RACF (continued)

Selection field type	Description
"IPv6 addresses" on page 907	Lists the syntax and rules for selection based on IPv6 addresses.
Instruction-scan fields	These are documented with the NEWLIST type in which the fields are defined. For information about these fields, see Chapter 13, "SELECT/LIST Fields," on page 953.
Other (special format) fields	Typically, these fields cannot be used for SELECT and EXCLUDE processing. They are used only to format output. Exceptions to this rule are documented in "Controlling report and display output for LIST family commands" on page 795. Typically, these fields are of a non-standard format, a time zone field for example.

The following sections describe the different field types listed in Table 312 on page 900. For more information, see "Examples - SELECT and EXCLUDE statements" on page 908.

Character fields: Character fields can be used for `SELECT` and `EXCLUDE` processing in the following ways.

- **Normal string searches** for strings that do not contain wild card characters. These strings are not considered case-sensitive. When a single value is specified, all relational operators are supported. When multiple values are used, only the `=`, `<>`, and `¬=` relational operators are supported. The following example shows a valid search string.

  ```
  select system>SYS1
  select system=(sys1, sys3)
  ```

- **Pattern string searches** for strings containing the following wild card characters: `%`, `*` and `**` or `*` and `-`, with `MASKTYPE=ACF2` . These strings are always converted to uppercase. A list of patterns strings can also be specified. Only the `=`, `<>`, and `¬=` relational operators are supported in pattern string searches.

  ```
  select system<>s%s%
  select system=sys*
  select system<>(sys*, mls*)
  ```

- **Substring searches**. You can select one substring or a list of substrings by specifying a colon (:) after the relational operator. As an alternative, any search string in a list can be prefixed by a colon to indicate a substring search that can include exact matches, substring searches, and pattern matches in a single list. Only the `=`, `<>`, and `¬=` relational operators are supported in pattern string searches.

  If a CARLa `LANGUAGE` statement is specified with the `DBCS` option, the substring scan uses a DBCS-enabled scan function. When this option is active, non-DBCS search arguments are *not* found in DBCS sections of the string, while DBCS search arguments are *only* found in the DBCS sections. See

  Note: The search results are unpredictable if the string has any invalid DBCS section–binary data that has a stray X'0E') for example.

  The following example shows the syntax for searching the system field for occurrences of the substrings `ml` and `sys`.

  ```
  select system=:(ml, sys)
  ```

Strings enclosed in single, double, or left quotations are not used as a pattern. This allows a search for a string or substring containing wild card characters, for instance a specific generic profile. These strings are treated as if they are not

case-sensitive unless appended by the conversion character **C**. Quoted, double-quoted and left-quoted strings can be appended by one of the following conversion characters:

G Treat quoted string as a generic.

X Convert string from hexadecimal (1 to 512 characters).

C Case sensitive string.

T Text string, not case sensitive.

Bitfields/Boolean values: Bitfields and Boolean values are typically used for truth or on/off values. In Security zSecure, truth/on values contain the value X'80'; all other values are false/off. The following selection types are supported.

- The field name alone indicates value is true.
- field=ON, field=YES indicates value is true.
- field=OFF, field=NO indicates value is not true.
- A quoted, double-quoted, or left-quoted value indicates a *bitmask*. This is a binary number with 0 for must-match 0, 1 for must-match 1, and dot (.) for don't care. One to eight bits can be specified; values shorter than 8 bits are padded with don't cares on the left.

The following examples indicate the valid usage.

```
* Select mlstable is TRUE */
select mlstable
select mlstable=yes
select mlstable=on

/* Select mlstable is FALSE */
select mlstable=no
select mlstable=off

/* Bitfield testing the most significant bit only */
select mlstable='1.......'

/* Bitfield testing the least significant bit only */
select mlstable='1'
```

Numerical fields: All numerical fields are treated as values of up to 4 bytes. When one value is specified, all relational operators can be used. When a list of values is specified, only the =, <>, and ¬= relational operators can be used. Any one value can be quoted or double-quoted, with the conversion characters F, X, and B.

F - treat as decimal.

X - treat as hexadecimal, which means that the length is one to eight character and the value is in the set {*0..9,A...F*}.

B - treat as binary, which means that the values *1* and *0*are supported.

The following example shows a valid usage.

```
select profcnt>5
select profcnt=(5,7,13)
select profcnt<>'ff'x
select profcnt='100'b
```

Instead of defining numerical values using digits, you can use the SYMBOLIC statement (`SYMBOLIC NUM name=value`) to define a symbolic name for a numeric value. The symbolic name can be used on its own or associated with a numeric default value that is used if the symbolic has not been defined. The default value is specified as `name|value`.

In the CARLa command input, the symbolic name must be defined before its first use. If you use the conditional specification, the value is the default that is used only if the SYMBOLIC statement has not been defined.

The following code sample defines the symbolic name `maxprof` with a value of `50` and a default value of `100`.

```
symbolic num maxprof=50
select profcnt>maxprof
select profcnt>maxprof|100
```

In this example, the value of `maxprof` in the first SELECT statement is interpreted as `profcnt > 50` as defined by the preceding SYMBOLIC statement. In the second SELECT statement, the select criteria is also interpreted as `profcnt > 50` because the value of `maxprof` is still taken from the SYMBOLIC statement. The select criteria would only use the default value `100` for `maxprof` if the SYMBOLIC statement was not present.

For more information, see “SYMBOLIC” on page 940.

Date fields: The following date formats are supported on input.

Julian date	ISO date	European format
YYDDD YYYY/DDD	YYYY/MM/DD YYYY-MM-DD 'YYYY MM DD'	DDMMMYY DDMMMYYYY DD/MMM/YY DD/MMM/YYYY DD-MMM-YY DD-MMM-YYYY 'DD MMM YY' 'DD MMM YYYY'

2-digit years are generally considered an error. However, you can suppress the error message by means of the SUPPRESS MSG= (51,53) command. In that case, 2-digit years are interpreted as prefixed with 19.

You do not have to specify leading zeros for the month and day of the month, e.g. 2001/2/3 is an acceptable input format for February 3, 2001.

In addition to the normal dates, zSecure Admin and Audit supports three special values.

Special values	Explanation
DUMPDATE	The date that the UNLOAD you have connected was created, or if you have connected the active security database, today.
NEVER	The date field has never been set, or has been reset to its initial state. E.g., PASSDATE=NEVER looks for users who have never changed their password. NEVER is only useful when using the = or <> operators.
TODAY	Today.

The special values can be followed by a displacement in days, either + or - followed by a decimal number, for example TODAY-30 , or a displacement keyword. Do not enter blanks before the displacement value. Note that not all date fields support DUMPDATE. For example, the certificate fields CERTSTRT and CERTEND do not allow this special value.

The following (RACF) keywords can be used as displacement keyword.

Displacement keyword	Explanation
INACTIVE	The number of days before inactive user IDs will be revoked
INTERVAL	The maximum number of days before a password change is required by a user.
SESSINTV	The maximum number of days before a session key expires

Date formats using blanks as separators must be surrounded by single quotes, double quotes, or left quotations. For selecting, a range of dates separated by a colon (:) is also supported, as indicated in the following examples.

```
SELECT DATE=01JAN1994                    /* One date */
SELECT DATE=(31DEC1993, 27SEP1994)       /* Two dates */
SELECT DATE>=01JAN1994 DATE<=31DEC1996   /* Date range */
SELECT DATE=01JAN1994:31DEC1996          /* Date range */
```

Time fields: For SELECT/EXCLUDE processing, values in the range 0000 to 2359 are supported. The default output size is five characters long (18:00 for six o'clock PM); use an overriding length of 8 to get seconds, and an overriding length of 11 to get 1/100 seconds. The time selection format 'HHMM' can be produced by a preceding CARLa run if you use overriding length 4 on a field in SMFTIME (for binary 4-byte fields such as this one) or TIME (for unsigned packed decimal fields as can for example be found in RACF profiles).

For SELECT/EXCLUDE processing, a range of times separated by a colon (:) is supported, as indicated in the following examples.

```
SELECT TIME=0800                          /* One minute */
SELECT TIME>=0900 TIME<=1600              /* Time range */
SELECT TIME=0900:1600                     /* Time range */
```

When specifying a time for SELECT/EXCLUDE processing, the time value is rounded to minutes before comparison. For example TIME<1745 selects any time up to 17:44:59.99, and excludes any time from 17:45:00.00, and TIME<=1745 selects any time up to 17:45.59.99, and excludes any time from 17:46:00.00.

Combined date and time fields: For SELECT and EXCLUDE processing any date format as specified in the preceding paragraphs is supported. If a time is also to be specified, it should be specified as `[h]h:mm:ss.cc`. You can leave out the centiseconds, the seconds or the minutes and seconds. These missing parts are rounded either up or down, depending on the logic of the select statement. Time and date should be separated by a space, and quoted. A range of combined dates and times separated by a colon (:) is supported.

The following examples indicate a cross-section of the valid usages.

```
SELECT DATETIME=23Sep2002            /*one day*/
SELECT DATETIME='23Sep2002 08:30'    /*one minute*/
SELECT DATETIME=23Sep2002:25/Sep/2002
                                     /*range of three days*/
SELECT DATETIME='23Sep2002 8:30:00.00':'23Sep2002 8:30:30'
                                     /*range of thirty seconds*/
SELECT DATETIME>'23Sep2002 22'       /*after ten o'clock*/
SELECT DATETIME<'23-Sep-2002 17:45'  /*up to 17:44:59.99*/
SELECT DATETIME<='23-Sep-2002 17:45' /*up to 17:45:59.99*/
```

Access levels: Selection of fields containing RACF access levels can be one of the following.

- Selection of a single value, for example FIELD=*level*. The relational operators =, <>, ¬=, <, >, <=, and >= can be used.
- Selection of any of a list of access levels, for example FIELD=(*level1*,*level2*,...). The relational operators =, <>, and ¬= can be used.

The following access levels are supported; listed in increasing sort order.

```
NONE
EXECUTE
READ
UPDATE
CONTROL
ALTER
```

The following examples show a valid usage.

```
/* Select access level of UPDATE or higher */
select access>=update

/* Select any access level but CONTROL and EXECUTE */
select access<>(control,execute)
```

Matching masks: The special keyword MATCH can be used to match a mask field with a specific value. This keyword is governed by the following syntax: MATCH[=](*field=value*). This specification selects those field values that cover the specified value. The field is treated as a mask of the appropriate type, EGN or NOEGN for example. The specified value cannot contain wild cards.

As an example, the following statement selects RACF access records (permits and member list entries used for RACF access checking) describing GCICSTRN class profiles that contain the value CEMT in the profile key or with a generic that matches the value CEMT. It prints the value(s) from the profile member list along with the access list.

```
newlist type=racf_access title="Access matching CEMT transaction"
  select class=gcicstrn match=(member_key=cemt)
  sortlist member_key profile id access
```

The MATCH keyword and syntax are valid for all NEWLIST types other than NEWLIST TYPE=RACF. However, most NEWLIST types do not have any fields that can contain masked values. Using MATCH for fields that cannot be masks can yield unpredictable results.

UNIX fields: For the file attributes, extended attributes and audit flag settings, it is possible to use the standard output format for equality selection (and for file attributes OCTAL is supported as well). However, it is possible to select on the

presence or absence of some separate attributes or settings as well using an extended syntax. Use of this extended syntax is signalled by quoting the specification and appending an 'M'.

File attributes: For file attributes, this syntax is an extension of the CHMOD output format. See “File attributes” on page 825). You can select on the attributes of one or two groups instead of all of them. You can also select on the presence or absence of separate bits rather than the entire group by using + (on) and - (off) instead of =. If you include multiple clauses, separate clauses with commas. Clauses are processed with AND logic. If the clauses contradict each other a syntax error is issued.

For example, you can specify the following selection statement to identify all files that have a SETUID property that is world-executable.

```
SELECT ATTR='u+s,o+x'M
```

Alternatively, the u, g, and o indications can be omitted entirely. In that case, the access indicated results in a match if a match exists for **any** of these groups. That is, OR logic is implied.

If an indication only applies to u and g(s) or o(t), it only matches for those groups (so *+t*M is equivalent to *o+tM*). This type of specification (referred to as *nonspecific*) cannot be combined with u, g, or o' specific clauses within the same mask.

The ATTR syntax also applies to the UNIX_ACCESS_ALLOWED and UNIX_ACCESS_USED fields of SMF NEWLIST. For these fields 'u', 'g' or 'o' specific clauses are evaluated by looking at the corresponding UNIX_ACCESS_ORIGIN field. For 'u' it should be 'user', for 'g' it should be 'group' and for 'o' it should be 'other'. Note that 'u' will **not** match with UNIX_ACCESS_ORIGIN='user ACL'. If UNIX_ACCESS_ORIGIN contains any value other than these three, only the "nonspecific" type of specification might match. In general the "nonspecific" type is the best option for the TYPE=SMF fields.

For example,

```
SELECT UNIX_ACCESS_USED='+w'M UNIX_ACCESS_ORIGIN=('user'c,'user ACL'c)
```

will select records where write access was used that was granted to a specific user (either through the owner bits, or through an ACL entry).

"Nonspecific" specification is also supported without the use of a mask (e.g., SELECT UNIX_ACCESS_ALLOWED=r--).

Extended attributes: For the extended attributes, this syntax is a similar extension of the EXTATTR output format (see “Extended attributes” on page 826).

For example,

```
SELECT EXTATTR='-s'M
```

selects those file that ignore the _BPX_SHAREAS setting and on execution of the file start a new address space anyway.

The following statement selects files without APF authorization, with program control, and with the share-AS attribute.

```
SELECT EXTATTR=-ps
```

The following statement, selects files without program control, and without the share-AS attribute.

```
SELECT  EXTATTR='-ps'M
```

Audit flags: For the audit flags, this syntax is a similar extension of the CHAUDIT output format. See “Audit flags” on page 826). (Note that the "nonspecific" alternative specification type is not supported here.)

For example,

```
SELECT AUDITFLAGS_AUDITOR='x+sf'M
```

selects those files for which the auditor has requested both success and failure auditing for execute access.

Note: The "nonspecific" alternative specification type is not supported here.

IPv6 addresses: Selection of an IPv6 address is supported only if the address is enclosed in quotes and adheres to the following rules.

- The IPv6 address value does not have any leading zeros in front of any block of 1 to 4 hexadecimal digits.

  Examples

  – **Supported address value:** 9::ABC

  – **Unsupported address value:**

  `09::ABC` has a leading *0* in front of *9*.

  `9::0ABC` has a leading *0* in front of *ABC*.
- For IPv6 address values, the rightmost largest sequence of *0* blocks (`0 : 0 : 0 : ... : 0`), including

  Examples

  – **Supported address values:**

  `1234:0:0:DEF0:1234::DEF0`

  `1234::1234:0:0:DEF0`

  `1234:5678:1234:5678:1234:5678::5678`

  – **Unsupported address value:**

  `1234::DEF0:1234:0:0:DEF0` has its leftmost rather than its rightmost largest sequence of *0* blocks abbreviated with `::`.

  `1234:0:0:0:1234::DEF0` has an abbreviation `::` that stands for a sequence of two *0* blocks, but the address has a larger sequence of *0* blocks.

  `1234:5678:1234:5678:1234:5678:0:5678` does not have its largest sequence of *0* blocks (consisting of a single 0 block) abbreviated with `::`.
- The address does not contain a *0* block right before or right after a `::`.

  Examples

  – **Supported address value:** `::` and `6789::FFFF`

  – **Unsupported address value:**

  `0::0` has a *0* block right before as well as a *0* block right after the `::`.

  `6789::0:FFFF` has a *0* block right after the `::`.

  `6789:0::FFFF` has a *0* block right before the `::`.
- For IPv4-mapped IPv6 addresses–addresses with 26 bytes *0* followed by 2 bytes *FF* followed by 4 other bytes, then its rightmost 4 bytes are written as an IPv4 address without any leading zeros.

Examples

– **Supported address value**: `::FFFF:1.2.3.4`

– **Unsupported address values**

`::FFFF:102:304` is not supported because it does not have its rightmost 4 bytes written as an IPv4 address.

`::FFFF:1.2.3.04` is not supported because the address has a leading *0* in front of the *4*.

- If the address is not an IPv4-mapped IPv6 address, then its last 4 bytes are not written as an IPv4 address.

  Examples

  Supported address values: `::102:304` and `9876::5432:102:304`

  Unsupported address values:

  `::1.2.3.4` is not supported because it is not an IPv4-mapped IPv6 address, but its last 4 bytes are written as an IPv4 address.

  `9876::5432:1.2.3.4` is not supported because it is not an IPv4-mapped IPv6 address but its last 4 bytes are written as an IPv4 address.

Examples - SELECT and EXCLUDE statements

Table 313 provides examples showing different criteria and tests that can be used to select and exclude records.

Table 313. Example for SELECT and EXCLUDE statement

Selection criteria	Example
Implicit AND function	This example selects data set profiles with a first qualifier of SYS1. It illustrates the AND function between the parameters on one SELECT statement. `select class=dataset qual=sys1`

Implicit OR function	This example selects data set profiles as well as DLFDATA profiles that match a filter SYS1.** (for example, everything with SYS1 as the first qualifier). It illustrates the OR function between multiple SELECT statements.
	`select class=dataset filter=sys1.**`
	`select class=dlfdata filter=sys1.**`

Explicit AND and OR function	This example selects data set profiles as well as DLFDATA profiles that match the filter `SYS1.**`–all profiles with *SYS1* as the first qualifier. It illustrates the explicit AND and OR functions and the use of parentheses.
	`select ((class=dataset or class=dlfdata) and filter=sys1.**)`
	As an alternative, a list of values could have been used.
	`select class=(dataset,dlfdata) filter=sys1.**`

Combining select and exclude	This example selects data set profiles with UACC greater than NONE, but excludes all SYS2 profiles. This illustrates the exception function of the EXCLUDE command.
	`select class=dataset uacc>none`
	`exclude filter=sys2.**`

Table 313. Example for SELECT and EXCLUDE statement (continued)

Selection criteria	Example
Multiple keywords	This example illustrates the multiple scan facility. It is much more efficient than repeated SELECT commands that would produce the same result. `select scan=('JONES',parker,'SMITH',perry)` **Note:** The SCAN= operand value is always converted to uppercase unless it is enclosed in quotations.
Segment field value selection	This example illustrates the use of the segment field selection mimicking TSO syntax. `select dfp(mgmtclas(fastmig))`
Field value filter	This example illustrates the use of a generic character in the field selection. The selection selects all profiles that have an owner field starting with 'SYS'. `select owner=sys*`
Field value scan	This example illustrates the use of the scan character in the field selection. The selection selects all user profile base segments that have a name containing JONES in an arbitrary position in the field. `select c=user s=base name=:JONES`
Class name filter	This example illustrates the use of a generic character in the class name. The command selects all base segments in the CICS transaction classes. `select c=%CICSTRN s=base`

MATCH	In this example, the command lists all profiles that could protect the data set specified using the MATCH keyword. The SEARCHKEY output field is used to sort on *best match*. If more specific profiles are deleted, the less specific profiles are used to protect the data set. (The less specific profiles are listed before the more specific profiles.)
	`newlist`
	`select class=dataset match=CKR.SCKRLOAD`
	`sortlist class searchkey(nondisplay) key proftype uacc`
	
	Note: If discrete profiles are listed, the data set is only protected by that profile if the indicated bit is set and the volume serials match. If these do not match, the most specific generic profile is used.

MATCH for grouping and member classes	The MATCH keyword matches both member profiles and the member list of grouping profiles. When the CLASS keyword is also used and specifies a member class, the grouping class is automatically included. The following example displays all profiles that could protect a CICS transaction.
	`newlist`
	`select class=tcicstrn match=prodcics.cemt`
	`sortlist class key memlst / acl(header)`
	
	If both CLASS and MATCH are specified, these keywords *must* be specified as the first keywords of a SELECT/EXCLUDE clause or WHERE clause.

Table 313. Example for SELECT and EXCLUDE statement (continued)

Selection criteria	Example

ACL repeat group combination (access list entries)	The following example uses the ACL(...) keyword to select the profiles where any defined user that is not RESTRICTED has unconditional access higher than READ. For each profile the UACC and the unconditional access of ID(*) are printed in separate columns.
	`newlist title="Unspecific access of update or more"`
	`  select ACL(id='*' missing(whenprof) access>READ) or,`
	`  (not(ACL(id='*' missing(whenprof))) uacc>READ)`
	`  define definedacc("ID(*)",aclaccess) subselect,`
	`  ACL(id='*' missing(whenprof))`
	`  sortlist class key uacc definedacc`

USR repeat group combination (userdata entries)	This example illustrates the use of the USR(...) keyword. The following example displays the profiles where the userdata field PHONE contains a number starting with area code 555 (assuming the installation defined such userdata fields) with any phone numbers included in them.
	`newlist`
	`  select usr(usrnm=phone usrdata=555*)`
	`  def phone subselect usr(usrnm=phone)`
	`  sortlist class key phone`

Custom field	This example selects all users in finance and shows the NAME fields and all custom fields.
	`newlist type=racf`
	`select class=user segment=csdata`
	`custom_data(cskey=dept csvalue='finance')`
	`sortlist key(8) name custom_data`
	An alternative way of making the selection without showing the field list header as a prefix is shown in the following example.
	`newlist type=racf`
	`select class=user segment=csdata dept='finance'`
	`sortlist key(8) name dept`

SHOW

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

This command can be used to request fixed-format reports where the sort order cannot be changed, unlike reports requested with the REPORT option, or NEWLISTs with a user-defined layout.

CKRSITE
List the installation-defined settings stored in the CKRSITE module on the SYSPRINT file. The CKRSITE module and its contents are described in *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*. This command issues message CKR0525.

CLASSES
CLASS
List the number of generic and discrete profiles for each resource class, as well as the number of segments per entity type. This option is not supported in restricted mode. This includes CARLa script CKRLCLAS.

ICHNCV00
Show the RACF naming convention table ICHNCV00 in assembler format on the SYSPRINT file. This issues message CKR0594.

TEMPLATES
TEMPLATE
List all fields present in the templates, together with the default input and output format assigned by Security zSecure, and a description of the main application of the field. The sort order is by field name. Sample output is present in Chapter 3, "RACF Audit Guide," on page 255. This includes CARLa script CKRLTEMP.

ZAP
This is an alias of CKRSITE.

Example - show templates

The following command requests a listing of all template fields.

```
show templates
```

Sample output is included in "TEMPLATE - Template field properties" on page 284.

Example - show CKRSITE

The following sample output shows a listing of the CKRSITE module with installation-defined settings. Note that the CKGRACF command gives a more complete listing of the CKRSITE module.

```
show ckrsite
CKR0525 00 Contents of CKRSITE module:
           Class:              XFACILIT
           Authority:          SINGLE
           Force restrict:     N
```

This message indicates that the CKGRACF, menu option and action authorization checks are done in class XFACILIT; that the default multiple-authority setting is SINGLE; and finally that Security zSecure is not forced in restricted mode.

Example - show ICHNCV00

The following sample output shows a listing of the RACF naming convention table ICHNCV00. For each system, the date and time is listed that the module was created, followed by reconstructed source code.

```
show ichncv00
CKR0594 00 System 3090: using ICHNCV00 of 01/11/95 17.29
           Can be simulated by Security zSecure
           Reconstructed ICHNCV00 source code follows
CHECK1   ICHNCONV DEFINE,NAME=CHECK1
         ICHNCONV SELECT,COND=((GQ,1),EQ,'SYS1')
         ICHNCONV ACTION,SET=((UQ,0),'RCOPROB')
         ICHNCONV END,NEXT='SUCCESS'
         ICHNCONV FINAL
```

SIMULATE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

Use the SIMULATE command, or its abbreviation SIM, to change a number of settings or to add features globally in the CKRCARLA run. You can use this command to test scenarios without actually making changes in the security database.

SIMULATE commands have several subtypes. The subtype is entered as the first positional parameter on the command.

```
CLASS=class [ACCESS=[level | READ] [SENSITIVITY=Site<text>
PRIO={2|3|4|5|6|7|8|9} [ID=S<id>] CONCERN='concern
text'][[RESOURCE_LOCATION|RESLOC]=name] RESOURCE=(name, ...)
```

Applies to the RESOURCE field in the NEWLIST TYPE=RACF_ACCESS and to data sets and resources in NEWLIST TYPE=TRUSTED. When this option is specified, the program uses resource simulation to show which permit is used for which resource for RACLIST-merged grouping and member profiles. For CLASS=DATASET, this statement adds a sensitive resource and optionally adds resource locations if locations are reported by NEWLIST TYPE=REPORT_*.

For the command syntax, CLASS must be the first parameter and RESOURCE the last parameter. The CONCERN parameter must be specified as the last optional parameter before the RESOURCE parameter. If the CONCERN parameter is specified, the parameters PRIO and SENSITIVITY must also be specified. The RESOURCE parameter can contain a list of resource names separated by commas or blanks. End of line characters between parentheses are ignored. Resource names are case sensitive. The SIMULATE command can be combined with the SUPPRESS AUTO_RESOURCE command so that only the resources specified on SIMULATE commands are included in the output. See the SUPPRESS command.

To influence how many resources get reported, use the REPORT RESOURCE command to automatically include sensitive general resources, or use the REPORT DATASET command to automatically include sensitive data sets, or use the REPORT RESOURCE DATASET command to include both. Before using the REPORT commands, consider how much output you require, especially when including the DATASET option. If you do not specify any additional selection criteria (SELECT command), adding many resources by using the SIMULATE command combined with the use of the RESOURCE field in NEWLIST TYPE=RACF_ACCESS can result in an exceedingly high volume of output. The amount of output generated equals the product of the number of resources in system multiplied by the number of permits in the profiles that protect the resources.

The following classes assign a non-standard meaning to the member list and are not supported for resource simulation: CONNECT, DIGTNMAP, DIGTCERT, DIRACC, DIRAUTH, FSSEC, FSOBJ, GLOBAL, GMBR, GROUP, IDIDMAP, NDSLINK, NODES, NODMBR, NOTELINK, PMBR, PROGRAM, RACFVARS, RVARSMBR, SCDMBR, SECDATA, SECLABEL, SECLMBR, UNIXMAP, USER, VMBR, VMEVENT, VMXEVENT, and VXMBR.

The following definitions of the optional parameters for the SIMULATE command provide descriptions, syntax, and processing considerations.

[ACCESS=[level | READ]
The minimum access level associated with the RISK field. READ is the default.

CONCERN=['text' | "text" | `text`]
Audit concern description that explains the authority granted by the sensitive access level defined in the ACCESS field. The CONCERN parameter is reported in NEWLIST TYPE=TRUSTED. Specify the CONCERN

parameter as the last optional parameter before the RESOURCE parameter. The maximum length is 64 characters. The description text must be enclosed in quotes. If the optional CONCERN parameter is specified, the PRIO and SENSITIVITY parameters must also be specified.

PRIO={2|3|4|5|6|7|8|9}
Audit priority is a number in the range of 2–9 that determines the display sort order of the audit concern. Priority 2 represents the lowest priority. Priority 1 is reserved for inactive userids that have been revoked or suspended. Priority 9 is very high, system-wide systems programmer privilege. The default priority for CICS resources is 2, but the PRIO parameter can be used to increase the CICS audit priority. If the optional PRIO parameter is specified, the CONCERN and SENSITIVITY parameters must also be specified.

SENSITIVITY=Site<text>
An 11-character string that denotes the sensitive resource type. The text string must start with 'Site'. The case of the text string is preserved.

ID=S<id>
The ID=*parm* can be specified on the LANGUAGE statement that specifies the translation. The ID must start with an 'S' and its maximum length is 8 characters. If the optional ID parameter is specified, the CONCERN, PRIO, and SENSITIVITY parameters must also be specified.

RESLOC=<resloc> | RESOURCE_LOCATION=<resloc>
Optional specification of the location of the CLASS RESOURCE. The CLASS_RESOURCE location is returned in various reports in the RESOURCE_LOCATION field. The maximum length is 35 characters. The text is converted to uppercase.

CNGRACF
CNGRACF CLASS=*class*
CNGRACF COMPLEX=*complex*
CNGRACF COMPLEX=*complex* **CLASS=***class*
CKGRACF
CKGRACF CLASS=*class*
CKGRACF COMPLEX=*complex*
CKGRACF COMPLEX=*complex* **CLASS=***class*
These command subtypes can be used to influence the CKGRACF scope determined by the program. SIMULATE CKGRACF causes resources of the form CKG.** to be checked. SIMULATE CNGRACF causes resources of the form $CNG.** to be checked. The two command subtypes are mutually exclusive on the complex level. If the COMPLEX= keyword is used, only the specified complex is affected by the command. If the COMPLEX= keyword is omitted, all complexes that are not the target of a specific SIMULATE CNGRACF or SIMULATE CKGRACF command are affected. A complex that is the target of neither is processed like for SIMULATE CKGRACF, unless it contains an UNLOAD file made by an old version of the product that still used the $CNG.** resources, in which case SIMULATE CNGRACF processing applies. The CLASS= keyword specifies the general resource class to be checked. If omitted, CKG.** resources are checked in the class specified in the CKRSITE module (or XFACILIT if there is none), whereas $CNG.** resources are by default checked in FACILITY. These command subtypes are not supported in restricted mode.

DMSPARMS *prm+val*
This command sub-type can be used to simulate the effect of changing DMS parameter settings, or, if they are missing from the CKFREEZE file, to tell the

program how they are set. The parameter name and value are specified without intervening blanks, as in the DMS option members. The following parameters are supported and used.

RACFALWZ
Always-call must be Y to process data sets that are not RACF-indicated.

RACFBKUP
Determines the way discretes are processed.

RACFPRED
Determines whether an existing discrete will be used or deleted when a data set is restored.

RACFSUPP
Support must be Y to support RACF-indicated data sets.

RACFPROC
Process RACF profiles can be Y to be able to process data sets that have lost their discrete profiles.

RACFNEWN
Process NEWNAME must be N for a safe system.

RACFDVOL
Volume for discretes

RACFUSID
High-level qualifier for archive data sets.

SECURVOL
Determines whether DASDVOL profile are checked first.

POLICY *policy*
This option is only used in the audit products. It sets the policy against which settings are checked. It causes additional audit concerns to be raised. Also, it increases priority for direct violations of the policy to be at least 40. It is by no means a complete check on all requirements for the policy.

The policy can be one of the levels C1, C2, or B1 from the US standard DOD 5200.28-STD, usually called 'orange book'. C2 is equivalent to the Protection Profile CS1 (Commercial Security 1) of the Common Criteria. If no explicit policy is requested, the built-in IBM Security zSecure audit policy will be used, somewhere between C1 and C2 but with more emphasis on auditing.

RACF_ACCESS

This option controls under which profile, profile member, and access list entry the Access Monitor records will be reported in `RACF_ACCESS NEWLIST`.

When `SIMULATE RACF_ACCESS` is **not** specified, the result fields in the Access Monitor records are used to locate the profile name in the current RACF input source and if the profile exists, occurrences are counted towards that profile.

When `SIMULATE RACF_ACCESS` is specified, the result fields of the Access Monitor records are not used, and a simulation is done of what RACF would do given the current RACF input source. The profile resulting from that simulation is used for recording and counting purposes. This option also determines whether the Access Monitor records are counted as success, violation, or unexpected.

Note that specifying the `RACF_ACCESS NEWLIST` option without using the `SIMULATE RACF_ACCESS` option precludes the use of the `SIM*` fields in `RACF_ACCESS NEWLIST`. That is, when you set up a reporting query using both the `RACF_ACCESS` and `ACCESS` NEWLIST types together, you must specify the `SIMULATE RACF_ACCESS` option to include SIM* field data in the report results. If you do not specify this option, the `SIM*` fields will be empty.

RDEF FACILITY IRR.PGMSECURITY APPLDATA(' *mode*')
Simulate that FACILITY profile IRR.PGMSECURITY has APPLDATA('*mode*'). This simulates the mode in which RACF Program Control runs. The following modes are supported.

- BASIC for basic security mode
- ENHWARN for Enhanced-Warning security mode
- ENHANCED for Enhanced security mode

This command is used with VERIFY PADS (see "VERIFY PADS" on page 943). You can evaluate the commands that are generated by VERIFY PADS before configuring RACF in the mode.

RESTRICT
This option causes Security zSecure to behave as if it were called in restricted mode. This can be used before introducing restricted mode to study the effect, or to develop Security zSecure input that has to be usable in PADS mode. There are no further parameters to the command.

SENS *type* **SENSITIVE ...**
This command subtype can be used to add system data sets to be considered integrity sensitive by the REPORT SENSITIVE command and newlists of type REPORT_SENSITIVE, SENSDSN or TRUSTED. The *type* can be:

LINKLIST
non-APF data sets in LNKLSTxx

PROCLIB
JES2/JES3 non-STC/TSU procedure libraries

Access of UPDATE or more will be considered an exposure.

SENS *acc cls name*
SENSITIVE ...
This command subtype can be used to add data sets to be considered by the REPORT SENSITIVE command and NEWLIST types: REPORT_SENSITIVE, SENSDSN, or TRUSTED. For SENSDSN it is only effective for queries that read the entire CKFREEZE file for different reasons (this is not ensured because of this command). The data sets are only processed if they exist; the specification is ignored if a matching data set does not exist. Three additional positional parameters must be given.

acc
gives the access that must be considered an exposure. It must be READ or UPDATE, or abbreviated R or U.

cls
Class name, must be DATASET, D, or DSN.

name
Resource name, fully qualified data set name (without quotations).

SETROPTS *options*
SETR *options*
This allows one to simulate the effect of changing selected system-wide RACF options. The syntax of the rest of the command is similar to the RACF SETROPTS command. The SETROPTS options supported are MODEL, TAPEDSN, PROTECTALL, EGN, ERASE, and WHEN with their respective subparameters and opposites. The SIMULATE SETROPTS command is not supported in restricted mode.

SHARED
SHARE
NONSHARED
NOTSHARED
UNSHARED

NOSHARED
NOSHARE
NONSHARE
NOTSHARE **SYS=***list* **VOL=***list* **SYS=***list* **VOL=***list*

This command subtype can be used to override the default shared DASD layout interpretation (which is based on the UCB settings). The command accepts two optional parameters: SYSTEM (or its aliases SYSTEMS, SYST, and SYS), and VOLUME (or its aliases VOLSER and VOL). Both parameters accept a single value (system name / volume serial), or a list of values enclosed in parentheses and separated by commas. The scope of the SHARED / NONSHARED command is determined by the two parameters. If absent, it applies to all systems and all volumes. If no volume is included, it applies to all volumes in the systems mentioned. If no system is included, it applies to all systems for the volumes mentioned. If multiple commands apply to the same volume and/or system, the order of priority for each system/volume combination is shown in the following list.

1. Sim (non)shared System= Volume=
2. Sim (non)shared Volume=
3. Sim (non)shared System=
4. Sim (non)shared
5. Use Shared setting from UCB.

If the system and volume parameters are both omitted, the command must be terminated by a semicolon.

SMF=*number*
SYSTEM=*smfid*
FORMAT=*fmt*

Interpret the indicated SMF record number as a record of type *fmt*. This specification might be needed if you do not have an appropriate CKFREEZE for the system you want to analyze *fmt* records from. If a CKFREEZE is present, the program should automatically select the proper format. When no *smfid* is specified, the command affects all systems. Otherwise, a CKFREEZE with the *smfid* specified should be present, or the command will be ignored.

When multiple record numbers are specified (maybe one from a CKFREEZE and one from SIMULATE) for one format, all will be interpreted as being of that specific format.

The following formats are supported.

- ACF2
- AIM
- HSM0
- HSM1
- OMEG
- SECURPASS

TODAY=*date*

This parameter can be used to turn out reports as if it were the specified date. The supported format for date values can be found in “Date fields” on page 903.

This is especially useful for regression testing, and answering what-if questions. The main area of impact is output that depends on a comparison of date values with the current date (like revoke status). The datestamp printed on the output will also list the simulated date, except the first (or all) pages in the SYSPRINT

file. Faked time stamps might be recognized when they display the time as well as the date, because the time has been set to the impossible `HH:MM:SS.CC` value *`99:00:00.00`*. The date value can also be used to recognize unloads that have been unloaded with a simulated today value. The parameter is not supported in restricted mode.

Example - Including tape data sets for VERIFY

The following example shows how to include the tape data sets into consideration for VERIFY NONEMPTY.

```
simulate setropts tapedsn
verify nonempty
```

SMFCACHE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•	•			•	•	•

The SMFCACHE command controls the SMF job tag system. It can be used outside the context of a NEWLIST TYPE=SMF command, and has the following parameters.

ON
Turn the job tag system on (default).

OFF
Turn the job tag system off.

MINIMAL
Turn the job tag system on, but do not delay records.

RECORDS= *number*
Set the overall amount of records that might be delayed.

JOBRECORDS= *number*
Set the per-job tag amount of records that might be delayed.

VERBOSE
Print job tag statistics during run.

The RECORDS parameter sets the number of records that might be delayed for all incomplete job tags combined, while the JOBRECORDS sets the number of records that might be delayed for any one incomplete job tag. The value of RECORDS should be larger than the number of multi-user address spaces multiplied by the value of JOBRECORDS. Default values are 2000 (RECORDS) and 100 (JOBRECORDS).

The MINIMAL parameter turns on the job tag system and sets the value of RECORDS to zero. This means that records are never delayed, but any record with a complete job tag can still be completed. Use the MINIMAL parameter when memory is tight, or when you are processing SMF data on TSO.

The VERBOSE parameter causes Security zSecure to print a statistic message each time a job tag with cached records is completed and each time a tag cannot be completed as well as a message detailing memory usage statistics at the end of SMF processing. These messages can help determine the proper SMFCACHE settings and SMF interval time at your installation. The messages codes are

CKR0455, CKR0456 and CKR0457. Additional information about these messages is available in the *IBM Security zSecure: Messages Guide*.

SORTLIST

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

This command has the same syntax as the LIST command. It is followed by a list of field names. However, unlike the LIST command, the SORTLIST command lists records in ascending sequence of the fields to be listed. If you specify the class and key fields as shown in the following example, the class and profile key of the selected records are output sorted in ascending sequence.

```
sortlist class key
```

Another difference is that in the scope of a NEWLIST command, the SORTLIST generates page and column headers by default, while the LIST command does *not* generate any page and column headers by default.

However, the sort order is based on the *internal representation* of the fields. This might become apparent when the field is formatted by a format. Different internal values might result in the same output string (for instance, with a date format both the null and the undefined values format as blanks, while they are at the opposite end of the sort spectrum).

To change the sort order from the default *column order* to another order, add the sort keys in front with the NONDISPL attribute.

For fields that are part of a *repeat group*, the position of the record in the output is based on the value of the first occurrence of the field in the repeat group (this is the value listed in the first output line for the profile). The order of the repeat group entries themselves is not sorted, but the same as it appears in the input source. For example, a command SORTLIST user ID KEY would sort based on the first user ID in the access list.

To remove duplicate entries from a SORTLIST, use the NEWLIST NODUP parameter.

For a further discussion of the syntax as well as examples, see the reference section on LIST.

SUMMARY

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

Use the SUMMARY command or its variant DSUMMARY for listing data in ISPF panels, to create summary reports of selected data. The summary reports can also contain the selected data itself.

The basic features of the SUMMARY command are explained in an extended example in the "Basic Concepts" followed by more detailed information. More detailed information is available in the remaining topics.

Basic concepts

The following extended example illustrates basic concepts for using the SUMMARY command. The data in the example is not based on real-world information.

Table 314 represents data from eight records that comes from the following fields: CLASS, OWNER, QUAL, and KEY fields. This CARLa statement to produce this report is: SORTLIST CLASS OWNER QUAL KEY

Table 314. Record data - CLASS, OWNER, QUAL, and KEY data for eight records

Class	Owner	Qual	Key
DATASET	ONE	SYS1	SYS1.ONE.AA
DATASET	ONE	SYS2	SYS2.ONE.AA
DATASET	ONE	SYS2	SYS2.ONE.BB
DATASET	TWO	SYS1	SYS1.TWO.AA
DATASET	TWO	SYS1	SYS1.TWO.BB
DATASET	TWO	SYS2	SYS2.TWO.AA
DATASET	TWO	SYS2	SYS2.TWO.BB
DATASET	TWO	SYS2	SYS2.TWO.CC

CARLa command statement: SORTLIST CLASS OWNER QUAL KEY

You can create sorted output like that shown in "Using the summary statement - examples" on page 927 using the SORTLIST and DISPLAY commands.

Using the data shown in "Using the summary statement - examples" on page 927, you can use a SUMMARY command to create an overview that only shows the QUAL field data for each CLASS, OWNER combination. This summary can be created using a two-level summary: Summarize the information for each CLASS and OWNER combination and include only the information from the QUAL field. The CARLa statement to produce this report is: SUMMARY CLASS OWNER * qual.

Table 315 on page 920 shows the results of the two-level summary using the example data.

Table 315. Two-level SUMMARY report - QUAL field data summarized by CLASS and OWNER for eight records

Class	Owner	Qual	Count
DATASET	ONE		3
		SYS1	1
		SYS2	2
DATASET	TWO		5
		SYS1	2
		SYS2	3

CARLa command statement: SUMMARY CLASS OWNER * qual

In this summary, you see the following results:

- The CLASS, OWNER combination DATASET ONE occurs three times.
- The CLASS, OWNER combination DATASET TWO occurs five times.
- The combination DATASET TWO, QUAL SYS1 occurs two times.
- The combination DATASET TWO, QUAL SYS2 occurs three times.

The summary does not include the full data. In this example, the data from the KEY field is not listed. You can create a summary like this using only the SUMMARY command. The **Count** field is an example of a *statistic variable*. Statistics variables are simple statistics that are added automatically. You can also create user-defined statistics to include in the summary.

The following example shows how to create a summary that provides an overview of the OWNER fields for each CLASS, and the QUAL fields for each CLASS, OWNER combination. This summary can be created using a three-level summary: CLASS by OWNER by QUAL. The CARLa statement to product this report is: SUMMARY CLASS * OWNER * QUAL.

Table 316 shows the results of the three-level summary using the example data.

Table 316. Three-level SUMMARY report - CLASS data summarized by OWNER and then QUAL value for eight records

Class	Owner	Qual	Count (Statistics variable)
DATASET			8
	ONE		3
		SYS1	1
		SYS2	2
	TWO		5
		SYS1	2
		SYS2	3

CARLa command statement: SUMMARY CLASS * OWNER * QUAL

Reviewing the results shown in Table 316, this summary report provides a count of all DATASET records (eight). This example shows that extra summary levels do not add any values, but add more statistic information. When user-defined statistics

are added such as minimum value, maximum value, counts, and average value, additional summary levels display additional statistics, thereby giving a better overview of the data.

The example in Table 316 on page 920 was created using a simple SUMMARY command. The following example shows how to mix raw data with the summary data, interleaving the KEY field data with the summary and statistics data. The CARLa code to produce this report is:

```
SORTLIST key
SUMMARY CLASS * OWNER * QUAL
```

Table 317 shows the results of this type of report using the example data.

Table 317. SUMMARY report that includes summary information mixed with raw data

Class	Owner	Qual	Count	Key (Detail lines)
DATASET			8	
	ONE		3	
		SYS1	1	
				SYS1.ONE.AA
		SYS2	2	
				SYS2.ONE.AA
				SYS2.ONE.BB
	TWO		5	
		SYS1	2	
				SYS1.TWO.AA
				SYS1.TWO.BB
		SYS2	3	
				SYS2.TWO.AA
				SYS2.TWO.BB
				SYS2.TWO.CC
SORTLIST key SUMMARY CLASS * OWNER * QUAL				

Table 317 shows that the non-summarized **KEY** data is included as *detail lines* , indented to the right of the summary. Detail lines do not have any summary statistics.

These examples show some of the basic features of the SUMMARY command. You can find information on other available features and additional examples by selecting a topic from the SUMMARY command introduction. (See “SUMMARY” on page 918.

Summaries in batch and ISPF

Use the SUMMARY command to create interactive summaries in ISPF and summary reports in either batch or ISPF. You can use this command within the context of a NEWLIST statement in combination with a DISPLAY command (interactive summary) or SORTLIST command (summary report) to include detail data.

Statistic or boolean variables to be included in a summary report are defined by the DEFINE command. (see “DEFINE” on page 750); the output modifiers that can be used in a summary are described with the LIST command (see “LIST family of commands” on page 794).

The SUMMARY command can be used for interactive and batch summary reports; it has an equivalent, DSUMMARY, which always generates interactive summaries. The behavior of the commands is detailed in the following table.

	SORTLIST	DISPLAY	No detail
DSUMMARY	ISPF	ISPF	ISPF
SUMMARY	file	ISPF	file

The DSUMMARY command always generates an interactive ISPF summary, while the SUMMARY command only does so when combined with DISPLAY.

Summary terms

The basic concept in a summary is the summary level. A summary level is a combination of one or more fields used as summary key; every key value is kept once per summary level, and is crossed with the summary levels above and below. In the preceding summary examples, first (CLASS OWNER) and QUAL were used as keys; later CLASS, OWNER, and QUAL were used. The (CLASS OWNER) combination is called a compound key.

In the SUMMARY command, summary levels are separated by an asterisk (*). Each summary level must contain at least one key variable. A field is always a valid key variable, unless it has been converted to a statistics variable by using one of the key modifiers listed in Table 318 on page 924. Other valid key variables are define variables of the types in Table 289 on page 754. DEFINE variables of the type listed in Table 288 on page 753 are statistics variables. Statistics variables can be included in the SUMMARY command, but they are not valid key variables.

In an ISPF display, each summary level has its own display panel; in a batch report, each summary level has its own output line. The examples at the end of this section show output from sample summary reports; for an example ISPF summary, see menu option **AU.S** Status audit.

The following example shows a simple SUMMARY command, summarizing CLASS by OWNER by QUAL. This example does not include user-defined statistic variables; as described in the following text, a '**Count**' statistic is added automatically to each level.

```
newlist type=racf
 summary class * owner * qual
```

The following example shows a summary command with one summary level and two statistics: a count and a relative frequency. The example lists all classes in the RACF database, the count of profiles encountered per class, and the relative frequency of each class:

```
newlist type=racf
 define cnt count
 define frq freq
 summary class cnt frq
```

Summary types

When the SUMMARY command is used within a NEWLIST and no SORTLIST or DISPLAY appears before the SUMMARY command, the summary does not include any detail information. If a SORTLIST or DISPLAY command precedes a SUMMARY command within the same NEWLIST, the summary is mixed with detail information from the SORTLIST or DISPLAY.

When SUMMARY and SORTLIST are combined, the resulting summary is a report containing summary lines followed by those SORTLIST lines described by the last summary line. Such a summary report can be generated both in batch mode and using ISPF.

When SUMMARY and DISPLAY are combined, or DSUMMARY and SORTLIST, the resulting summary is an ISPF summary, where the relevant detailed information from the DISPLAY command is included as the lowest summary level. This kind of report is only possible using ISPF.

When a SUMMARY command is used without a preceding DISPLAY or SORTLIST command, the resultant summary is a report. Use the DSUMMARY command for an ISPF summary.

The following example shows the use of the SUMMARY and SORTLIST commands combined. The resultant summary report selects all profiles of class DATASET matching the filter SYS%.** (e.g. SYS1.BRODCAST). The resultant summary report contains one summary line for each first-level qualifier and a count of the profiles selected, followed by a list of the profiles and the profile type.

```
newlist type=racf
 select mask=sys%.** class=dataset segment=base
 sortlist key proftype
 summary qual
```

Repeat groups

When repeat groups are summarized, each occurrence of the repeat group is summarized. If a value occurs several times within a single repeat group, every instance is counted. The output of these multiple occurrences can be suppressed by the NEWLIST NODUP parameter. The way repeat groups are summarized has several implications:

- When a summary is combined with detail information, the same detail profile or record is repeated in the output for each different repeat group value. E.g. if a repeat group has values ONE and TWO, the detailed information is included both with ONE and with TWO.
- Detail information is counted once for every summary key it is combined with. If repeat groups are summarized, lowest-level counts might not seem to add up, since a detail occurrence is counted multiple times on lower summary levels, but is counted once on the higher (non-repeat group) summary levels.
- When the NEWLIST NODUP parameter is used, the output does not contain duplicates. NODUP applies both to the input of the summary (duplicates are eliminated before the summary) as to the detail level (duplicate lines are removed, but they are counted, for instance when summarizing a repeat group field).

Statistic variables

Summary reports can contain statistics variables. These variables can be defined by a prior DEFINE command or by using one of the field modifiers, listed in

Table 318, on a field of the (D)SUMMARY statement. Each statistic variable can be limited to one or multiple summary levels. When a statistic variable applies to multiple levels, each level is independent: each summary variable describes the instances summarized by its own level. The following example has two summary levels. The highest summary level summarizes classes and the count of records per class. The second summary level summarizes first-level qualifiers and the number of records for each.

```
newlist type=racf
 define profcnt count
 summary class profcnt * qual profcnt
```

A statistic variable propagates to all higher summary levels, unless a NOPROP output modifier is used. If the lowest summary level does not contain a statistic variable, a count variable is added that propagates to all higher summary levels.

Table 318 lists the DEFINE statistics that can be specified as field modifiers for the DSUMMARY or SUMMARY commands.

Table 318. Statistics that can be specified for the (D)SUMMARY commands

Kind	Category	Meaning
AVG AVERAGE	field	Average of fields summarized.
FREQ FREQUENCY	occurrence	Percentage that the condition clause evaluates to true among occurrences (when combined with a condition clause), or percentage of occurrences selected (without a condition clause).
MAX MAXIMUM	field	Maximum of fields summarized.
MIN MINIMUM	field	Minimum of fields summarized.
CPRX COMMON_PREFIX	field	The common prefix of the fields summarized. If the fields are the same then the field value will be displayed. If a (remove hard breaks) common prefix was found, the common prefix is displayed followed by a ">", for example, SYS>. If a common prefix is not found, either "+" or "<more>" is displayed.

Suppressing lower summary levels

A summary level and all its lower summary levels can be suppressed by giving all summary keys of that level the NONDISPL attribute. This works on all summary levels except the top one. Sometimes you just want to summarize on a field and know how many different values there are, but not see those values. For instance, when analyzing your 3 RACF databases, you might want to know how many different user IDs there are. A query like

```
n type=racf
 def #userids sumcount
 s c=user s=base
 summary class #userids * profile
```

will show you the desired number, but also all individual user IDs summarized over all complexes. By adding the NONDISPL attribute (abbreviated ND), you can signal you want to suppress those lines:

```
n type=racf
 def #userids sumcount
 s c=user s=base
 summary class #userids * profile(nd)
```

This will give just one line of output.

Conditional clauses for statistic variables

Statistic variables defined with the DEFINE command might have a condition, a so-called WHERE clause. The WHERE clause is evaluated for each occurrence that is summarized; the variable is only updated if the WHERE clause is true. This allows you to describe data or conditions that are not included in the summary itself, but that can be gathered from the data summarized.

In the following example, a summary is created of all SYS%.** profiles by owner. The variable FRQ shows the percentage of profiles with a UACC of NONE. Note that FRQ is only included on the highest summary level; the count variable PRF is included on the lowest level, and is propagated to the highest level.

```
newlist type=racf
 select class=dataset mask=SYS%.** segment=base
 define prf count     /* Profile count */
 define frq freq where(uacc=none)
 summary qual frq * owner prf
```

For more information about WHERE clauses, refer to the DEFINE command "DEFINE" on page 750.

Thresholds

Thresholds can be used to select only those summary lines (and related detail information) that contain a statistic variable matching a numerical threshold. Thresholds might only be specified for numerical statistic variables. In the following example, only those summary and detail lines for qualifiers with more than 10 data set profiles are printed:

```
newlist type=racf
 define profcnt count
 select class=dataset segment=base
 sortlist key proftype
 summary qual profcnt(>10)
```

Note that a threshold does not change the value of the statistic variables, sums and counts; it merely hides those summary lines (and underlying summary levels or detail information) that do not match the threshold.

The following types of thresholds might be specified: >, <, >=, and <=. Per summary level, each statistic might have only one threshold; however, you might specify several summary variables with thresholds per summary level.

Warning. By default, a threshold propagates with the statistic variable to higher summary levels. This means the same numerical threshold is also applied to the higher summary levels. For the < and <= thresholds, this may lead to unexpected results, since statistic variables like COUNT and MAX tend to be larger at the higher levels. If you do not want to apply the threshold at higher summary levels, specify the NOPROP output modifier, or specify the same variable, with a different threshold, on the higher summary level.

Overriding length

When a key variable in a SUMMARY command is used with an overriding length, the effect is dependent on the output type. If the field is a string, the overriding length is used during summary processing; if the field is not a string, the overriding length is only used during output.

If the overriding length is used during summary processing, only the first part of the key variable is used, as specified by the overriding length. So, if user ID(4) is used in a summary, all user ID fields that have the first four letters in common are treated as a single summary case.

An overriding length of zero makes no difference during summary processing (the full key, trimmed of trailing blanks, is used), but makes a difference with printing summary reports (non-ISPF). Each summary key that has overriding length zero shifts the detail lines to the left, allowing more detail information to fit on the output line. Use this option with care because it can reduce report clarity.

Changing the sort order

A summary is sorted level by level, column by column, in ascending order. The sort order can be changed by using the output modifier DESCENDING; this causes a column to be sorted in descending order. This output modifier can also be used on the SORTLIST fields, if detail information is included. The following example shows a summary sorted on ascending class and descending owner:

```
summary class * owner(descending)
```

You can also sort on a statistic variable. However, the variable must be included *before* the key variables for this to work. If you want to sort on a statistic variable, but want to display it behind the key variable, use the NONDISPLAY output modifier. The following examples show a summary sorted on count, one with the count displayed before the key variable, and one with the count behind the key variable. The NOPROP output modifier makes sure that the count is displayed on the lowest summary level only.

```
newlist
 define #owner(noprop) count
 summary class * #owner owner

newlist
 define #owner(noprop) count
 summary class * #owner(nondisplay) owner #owner
```

Indirect references in a summary

When using indirect references (see “Indirect reference or lookup” on page 764) in a summary, the summary is performed on the base value of the field, while the referenced value is printed. For example:

```
summary userid:name
```

performs a summary on user ID. Even though several users have the text 'TESTUSER' in the name field, they will appear on different summary lines.

Deciding which complex is meant to be used for the indirect reference can be rather involved in a summary:

```
newlist type=trusted
sortlist auditpriority auditconcern
summary userid_complex userid userid:name * complex resource
```

The field *complex* is the security database (complex) associated with the resource, the field *userid_complex* is the security database (complex) to which the user ID belongs.

The *complex* fields have to be added to make it possible for the summary processing to intelligently decide which security database contains the data needed in each case.

Security zSecure decides which complex to use as follows: Any summary field that has a name ending in 'complex' is considered to contain a complex name and is used to decide which complex to perform the indirect reference. First the summary level containing the reference is checked to see if it contains a complex field. If so, it is used. If not, the higher summary levels are tested in sequence, until one such field is encountered. If there are multiple complex fields on a single summary level, the first at the same level is used.

If no complex fields are found in the current and higher summary levels, the default complex, as mentioned in message CKR0615, is used.

Rules and restrictions

The following rules and restrictions apply to the SUMMARY command:

- At least one key variable must be per summary level, that is not just statistic variables.
- When a summary level has more than one key (a *compound key*), none of the key variables can be repeated fields.
- It is not possible to summarize statistic variables.
- It is not possible to summarize on look-up variables. As a result, the command `SUMMARY USERID:PGMRNAME` summarizes on user ID.
- Do not summarize on a repeated field if that repeated field is also included in the detailed information. If you try this type of summary, the summary processing requires a vast amount of memory. Use the NEWLIST NODUP parameter to cut down on memory use.
- The SUMMARY command can not be used in a MERGELIST/ENDMERGE.
- The EXPLODE and RESOLVE output modifiers cannot be used.

Conversions

Conversions can be used to replace segment name qualifiers of SUMMARY key field values with fixed characters. See the “CONVERSION” on page 737 CARLa command.

The general syntax for conversion application is as follows:

```
field(CONVERSION(conv1[,conv2...]))
```

In the following conversion example, conv1 is applied to the SUMMARY key field RESOURCE, then conversion conv2 is applied to the result, and so on. The conversions conv1 and conv2 are defined by the CONVERSION command (abbreviated as CONV).

```
newlist type=ACCESS
summary resource(CONVERSION(conv1[,conv2...])) class
```

Using the summary statement - examples

For examples using the summary statement with different types of data, formats, and options, choose from the following topics:

Example - basic summary

The following example shows a basic summary. All discrete data set profiles are summarized by high-level qualifier and owner. No detail information or summary statistics are included; a count statistic is added by default. The count for qualifier C#MA indicates that 3 discrete profiles start with C#MA, of which 2 are owned by C#MAINT and 1 is owned by C#MASCH.

```
newlist type=racf
 select discrete class=dataset segment=base
 summary qual * owner
 QUAL     Owner    Count
 BZOPRDG                1
          BZOPRDG       1
 C#MA                   3
          C#MAINT       2
          C#MASCH       1
 C#MBERT                4
          C#MBERT       4
 RDIVALG                1
          RDIVALG       1
 RDPSDAB                2
          RDPSDAB       2
 RDPSKAE                1
          RDPSKAE       1
 SYSHSM                20
          BZOPRDG       1
          C#MAINT       2
          C#MASCH       3
          C#MBERT       3
          RDIVALG       1
          RDOPHEG       6
          RDOPTRY       1
          RDPSDAB       2
          RDPSKAE       1
```

Example - apply thresholds

In the following example, the same data is summarized, but only those summary lines are included that show the high-level qualifiers with more than one profile, and the owners with more than one profile in a HLQ.

```
newlist type=racf
 select discrete class=dataset segment=base
 define cnt count
 summary qual * owner cnt(>1)
QUAL     Owner    CNT
C#MA                    3
         C#MAINT        2
C#MASCH                 2
         C#MASCH        2
C#MBERT                 4
         C#MBERT        4
RDPSDAB                 2
         RDPSDAB        2
SYSHSM                 20
         C#MAINT        2
         C#MASCH        3
         C#MBERT        3
         RDOPHEG        6
         RDPSDAB        2
```

Example - sort on statistic variables

In the following example, the same data is summarized again, this time sorted on descending profile count, then on qualifier and owner.

```
newlist type=racf
 select discrete class=dataset segment=base
 define cnt count
 summary cnt(descending) qual * owner
CNT      QUAL     Owner    Count
      20 SYSHSM                20
                 BZOPRDG         1
                 C#MAINT         2
                 C#MASCH         3
                 C#MBERT         3
                 RDIVALG         1
                 RDOPHEG         6
                 RDOPTRY         1
                 RDPSDAB         2
                 RDPSKAE         1
       4 C#MBERT                 4
                 C#MBERT         4
       3 C#MA                    3
                 C#MAINT         2
                 C#MASCH         1
       2 RDPSDAB                 2
                 RDPSDAB         2
       1 RDIVALG                 1
                 RDIVALG         1
       1 RDPSKAE                 1
                 RDPSKAE         1
```

Example - summary with detail information

In the following example, the discrete data set profiles starting with C are summarized; this time, a SORTLIST is specified before the SUMMARY in order to include detail information with the profile key and UACC.

```
newlist type=racf
 select discrete class=dataset qual=c* segment=base
 sortlist key uacc
 summary qual * owner
```

```
QUAL     Owner    Count    Profile key                                UACC
C#MA                    3
         C#MAINT        2
                          C#MA.C#MPROD.LOAD                          NONE
                          C#MA.C#MTEST.LOAD                          NONE
         C#MASCH        1
                          C#MA.QUALOWN                               NONE
C#MBERT                 4
         C#MBERT        4
                          C#MBERT.GDGMODEL                           NONE
                          C#MBERT.SYS1.CAUMODEL                      NONE
                          C#MBERT.SYS1.CAUNVSAM                      NONE
                          C#MBERT.SYS1.CAUVSAM1                      NONE
```

Example - summary statistics

In the following example, all data set profiles matching the mask SYS%.** are summarized by UACC. The variable FRQNON shows the frequency (percentage) where the UACC is NONE. Note that the variable COUNT is added automatically, since no summary statistics were included at the lowest summary level.

```
newlist type=racf
 select mask=sys%.** class=dataset segment=base
 define frqnon freq where uacc=none
 summary qual frqnon * uacc
```

```
QUAL     FRQNON   UACC    Count
SYS1           31               44
                  NONE          14
                  READ          28
                  UPDATE         2
SYS2            5               17
                  NONE           1
                  READ          12
                  UPDATE         3
                  CONTROL        1
```

Example - overriding length

In the following example, the discrete data set profiles of the owner are summarized on the first four characters; then the full owners are summarized again.

```
newlist type=racf
 select class=dataset discrete segment=base
 summary owner(4) * owner
```

```
Owne Owner    Count
BZOP                2
     BZOPRDG        2
C#MA               10
     C#MAINT        4
     C#MASCH        6
C#MB                7
     C#MBERT        7
RDIV                2
     RDIVALG        2
RDOP               15
     RDOPHEG       10
     RDOPROB        2
     RDOPTRY        2
     RDOPTST        1
RDPS                6
     RDPSDAB        4
     RDPSKAE        2
```

Example - overriding length zero

In the following example, an overriding length of zero is used. The SUMMARY command summarizes on the full length of the data, but include the detail data as if the summary has length zero. This can be used to fit more data onto a line; since the output becomes rather less clear, you should use this option with care.

```
newlist type=racf
 select class=dataset discrete segment=base
 sortlist key
 summary qual(0) * owner(0)
```

```
  Count    Profile key
BZOPRDG         1
 BZOPRDG        1
           BZOPRDG.FORT.LOAD
C#MA          3
 C#MAINT        2
           C#MA.C#MPROD.LOAD
           C#MA.C#MTEST.LOAD
 C#MASCH        1
           C#MA.QUALOWN
C#MASCH         2
 C#MASCH        2
           C#MASCH.TESTGDG.G0002V00
           C#MASCH.TESTGDG.G0003V00
C#MBERT         4
 C#MBERT        4
           C#MBERT.GDGMODEL
           C#MBERT.SYS1.CAUMODEL
           C#MBERT.SYS1.CAUNVSAM
           C#MBERT.SYS1.CAUVSAM1
RDIVALG         1
 RDIVALG        1
           RDIVALG.DARTS.MACLIB
RDPSDAB         2
 RDPSDAB        2
           RDPSDAB.PR.TEXT
           RDPSDAB.STRT.CLIST
RDPSKAE         1
 RDPSKAE        1
           RDPSKAE.ISPPROF
```

Example - getting rid of an extraneous leading blank

When a NEWLIST specifies both a SORTLIST and a combination of SUMMARY with the newline character /, each line is preceded by a single blank. This can be overridden by adding a "|" between the SORTLIST and the first field. For example:

```
newlist
s c=user s=base
sortlist | key(8)
summary class count /
```

SUPPRESS

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

Use the SUPPRESS command to stop the following types of processing:

- Verification of failure messages
- Command generation
- Scoping rules that are used in REPORT SCOPE or NEWLIST SCOPE statements

The SUPPRESS command is global in scope and applies to all commands. You can abbreviate the SUPPRESS command as: SUP, SUPP, or SUPPR.

Suppressing verification messages is useful if your installation has full-volume copies of critical volumes on hot standby with a different volume label, or emergency copies of the master catalog.

If you supply at least one CKFREEZE file, the following commands act on some resources and the profiles that protect them: COPY, MOVE, REMOVE and VERIFY commands. If you do not want to permit these operations, you can use the following SUPPRESS command to prevent them from changing the RACF database: SUPPRESS DELETEDATASETS COPYALIAS When this command is run, all resource deletion, catalog alias and copy operations are suppressed. As a result, zSecure does not generate the corresponding commands to change the RACF profiles nor does it read the CKFREEZE file when any of the following commands are run: COPY, MOVE, REMOVE, or VERIFY.

You can also stop certain types of processing on specified volumes and catalogs by using the CATALOG and VOLUME keywords with the SUPPRESS command.

Using SUPPRESS VOLUME has the following effects on processing:

- The volume is not processed.
- Catalogs residing on the volume are not processed, which is useful to prevent processing on a hot standby volume.
- Resource deletion commands for the specified volume have no effect.

However, using SUPPRESS VOLUME can cause errors related to resource deletion. Because Security zSecure considers a VSAM cluster to be an atomic entity, it does not consider cluster components on other volumes as separate entities. If you delete a cluster that has components on an excluded volume, the cluster is not deleted. This can cause VSAM inconsistencies that show up as error messages that need to be resolved using the IDCAMS DIAGNOSE command. Similarly, an apparent orphan NVR is not removed.

Note: The IDCAMS DIAGNOSE command requires special privileges to run under SMS.

If you exclude a catalog, zSecure does not generate any commands for that catalog. This can imply that ALLOCATEand FREE commands are generated to delete non-VSAM DSCBs for data sets appearing uncataloged. You can suppress this behavior by specifying the DELETEUNCATALOGED parameter. Note that DEFINE and DELETE ALIAS commands are issued against inactive master catalogs as well as active ones, insofar as they are addressable from the current system and are not excluded.

If you suppress resource deletion, no other messages are issued about the suppression. In addition, attempts to delete resources are not counted as suppressed.

If you decide to suppress only deletion of uncataloged data sets or delete commands specifying the NOSCRATCH keyword, the SYSPRINT still includes messages for those operations showing the commands that are generated if the delete command was permitted. You can explicitly exclude these messages by issuing a SUPPRESS command to stop the CKR0720 and CKR0727 messages.

Note: The NOSCRATCH keyword requires special privileges to run under SMS.

Because resource management avoids the use of the CATALOG keyword on IDCAMS commands, do not attempt to run the CKRCMD with an active master catalog that is different than the one that was current during the command generation.

Note: The CATALOG keyword requires special privileges to run under SMS.

If you need to re-run a command from another system, update the CKFREEZE files before running the command. Note that the following data sets are deleted:

- Data sets residing under a removed profile
- Data sets with a high-level qualifier (HLQ) matching the ID
- Data sets with a HLQ not protected by a profile

Data sets with a HLQ not protected by a profile exist if all data sets were not removed before removing the RACF profiles.

SUPPRESS command options

The SUPPRESS command provides a number of options that can be used to stop processing of verification of failure messages, command generation and scoping rules for use in REPORT SCOPE or NEWLIST SCOPE. These options are described in this topic. Some of the options, such as VOLUME, CATALOG, DELETEUNCATALOGED, and DELETEDATASETS are discussed in the introduction to the SUPPRESS command (“SUPPRESS” on page 932).

ACCESS_GDG_VERSION
To reduce the size of consolidated Access Monitor data sets, this option maps the G*nnnn*V*nn* qualifier of GDG generation resource names into a fixed string of GnnnnVnn for all TYPE=ACCESS input records. For example, G1259V00 is mapped to GnnnnVnn.

ACCESS_JESSPOOL_JOBID
This option is checked when reading TYPE=ACCESS input files. This SUPPRESS option converts the fourth JESSPOOL resource name qualifier (the job ID) into a

fixed string by using the following convention: the leading S, J, or T character is retained and the remaining characters in the job ID are replaced with a lowercase x.

ACCESS_JESSPOOL_DSID
This option is checked when reading TYPE=ACCESS input files. This SUPPRESS option converts the fifth JESSPOOL resource name qualifier (the data set ID) into a fixed string if it starts with a D by using the following convention: the leading D character is retained and the remaining characters in the data set ID are replaced with a lowercase x; if the data set ID includes a word such as GROUP, the word GROUP is retained as part of the resource name qualifier.

ADDSD
ADDDSD
ADD
Limits the commands generated by the COPY command to exclude the addition of data set and general resource profiles as well as profile members. For example, on a COPY USER=*user ID* TOUSER=*id* command, you can use this option to prevent the addition of data set profiles starting with *id* to the copy command.

AUTO_RESOURCE
The AUTO_RESOURCE parameter specifies that resource simulation operations are limited to the resources that are explicitly specified by SIMULATE commands. Resources that are determined from CKFREEZE data sets are not automatically included in the analysis.

CATALOG= *catname*
CAT=*catname*
This option suppresses error messages related to this catalog. In addition, resource copying and deletion will not take the contents of this catalog into account, so no IDCAMS commands will be (implicitly or explicitly) directed to it; this might lead to some data sets appearing uncataloged and being scratched from the VTOC directly (see DELETEUNCATALOGED).

CONNECTOWNER
Do not use the RACF connect owner field of group, user, or connect profiles during VERIFY PERMIT, REMOVE PERMIT and MERGE processing. For VERIFY PERMIT and REMOVE PERMIT this has the effect of not generating CONNECT commands to change the connect owner when it is a user ID or group which no longer exists. For MERGE operations no commands will be generated to set the connect owner field to any specific value.

COPYALIAS
Suppresses the generation of IDCAMS DEFINE ALIAS commands by COPY. This option is implied by SUPPRESS CKFREEZE. It is also automatically implied if no CKFREEZE file is allocated.

COPYCUSTOMDATA
COPYCSDATA
Suppress the generation of RACF commands to copy custom fields.

COPYUSERDATA
COPYUSRDATA
Suppress the generation of CKGRACF commands to copy user data.

DBIDCACHE
Suppress the translation of DB2 DBID, OBID, PSID, and DSID numbers to their respective database names, table space names, table names, and data set names. Some SMF type 100/101/102 record subtypes contain definitions of specific ID

numbers (namely, 24, 104, 105, 107, 142, 143, 144, and 258) and the bulk of the subtypes only refers to the objects by their numeric ID number. By specifying this option you can see what the SMF records really contain. The main use of this option is to assist in diagnosing problems in DB2_OBJECT and RECORDDESC that can be caused by providing the wrong order of SMF records or SMF with gaps. DB2 immediately reuses object ID numbers for new objects after an object has been deleted, and IBM Security zSecure cannot cope unless the SMF records are read in the proper order.

CKFREEZE
CKFREEZE IOCONFIG
Suppress the use of a CKFREEZE file with catalog information. This is useful for commands that would need CKFREEZE data to guarantee completeness and correctness of information about VSAM profiles, but also provide a lot of useful information without this info. If a cursory analysis is sufficient, you can save a lot of time by omitting the CKFREEZE file for analysis. For zSecure Audit for ACF2, this parameter is ignored for NEWLIST TYPE=SMF in restricted mode, and message CKR0521 is issued.

DELDSD
Limit the commands generated by REMOVE and MOVE operations to exclude deletion of data set profiles as well as other profiles or profile members to be removed. For example, on a REMOVE USER=*user ID* command, the deletion of all profiles starting with *user ID* can be prevented by specifiying this option. Note that this probably results in failure of a DELUSER command. If this parameter is specified, generation of DELGROUP commands that fail due to still existing data set profiles is suppressed. Message CKR1062 is issued to warn you that the command generation was suppressed.

DELETEDATASETS
To suppress the generation of all non-RACF commands by MOVE, REMOVE and VERIFY to delete data sets and catalog aliases. As a result, it might become unnecessary to read the CKFREEZE, which can gain you speed. This option is implied by SUPPRESS CKFREEZE; in turn it implies SUPPRESS DELETENOSCRATCH and DELETEUNCATALOGED. This option is also automatically implied by the absence of the CKFREEZE file.

DELETENOSCRATCH
Suppress the generation of IDCAMS DELETE commands with the NOSCRATCH keyword. A suppression message is issued instead of generating the commands. The NOSCRATCH keyword is only generated if a DELETE without it is not possible, because the data set is in several catalogs for example. Migrated data sets do not require this keyword. This option is implied by SUPPRESS DELETEDATASETS.

DELETEUNCATALOGED
To suppress the generation of ALLOCATE and FREE commands to scratch uncataloged data sets from the VTOC; if you want to supply the resource deletion commands to IDCAMS directly (instead of via TSO), you should specify this option, since IDCAMS only partially supports ALLOCATE and does not support FREE at all. This option is implied by SUPPRESS DELETEDATASETS.

ECKD
This parameter request fallback to non-ECKD channel program formats to be used with EXCP access to the RACF data sets. This reduces the size of sequential I/O operations from 3 tracks to 1 track.

FALLBACK
Suppress flagging second order error conditions. Presently this only affects VERIFY STC, where it means that ICHRIN03 entries are only verified for referential integrity when used (unused entries will still be flagged as such); note that currently unused STARTED profiles are never syntactically verified.

FMTABEND
Suppress user abend 931 which follows error message CKR0931, indicating a buffer overwrite in a text formatting procedure.

ICHCNX00
Suppress invocation of this RACF exit to determine the first qualifier. This command might be necessary if the exit depends on key 0 operation. This option is activated automatically if an abend condition is intercepted while calling the exit.

This option might also be required for processing data from another system. In this case, the `ICHCNX00` of the current system is used, not that of the subject system. This processing works if the systems have the same level of `ICHCNX00` exit code. If the systems do not have the same level exit, it might be better to suppress `ICHCNX00` processing.

The SUPPRESS ICHCNX00 command is not supported in restricted mode.

ICHNCV00
Suppress the use of the RACF naming convention table `ICHNCV00` in RACF and SMF reporting. The table normally used is the copy in the CKFREEZE file.

ICHRRNG
Suppress use of the RACF range table. This table maps the profile key to a specific RACF data set sequence number. The table used is the copy in the `CKFREEZE` file, unless the data source is a live RACF database. For a live database, the live `ICHRRNG` is used. Typically, profiles in the 'wrong' RACF data set are not seen by RACF and the IBM Security zSecure products. When you specify SUPPRESS ICHRRNG the profiles are processed and can be identified. This setting can cause messages to be issued for duplicate profiles, class not in CDT, and connect inconsistency, and other messages. Also, the pseudo field INRANGE can be used to identify the profiles.

ID= *id*
Suppress error messages and report lines concerning this user or group. In the case of multi-line messages, sometimes only the line containing the message id is suppressed.

INDEX
This parameter suppresses use of the RACF data set index and causes a sequential read.

INDEXCUTOFF
This option is for debugging and performance analysis purposes. It suppresses automatic fallback to sequential `I/O` in a RACF data set if the program gauges the number of indexed I/O requests to take longer. Because specifying this option can increase the elapsed time for some queries by more than a factor 12, do not use it with very large databases. Experience shows that queries that select 100,000 or more profiles perform badly while in indexed I/O mode. See also “LIMIT INDEXBIAS” on page 789.

The specification has no effect when `BDAMQSAM` has been specified. This option implies `SUPPRESS DELETEDATASETS` and `COPYALIAS`

MANAGERACFVARS
To suppress interpreting keys and members in RACFVARS profiles to represent users and groups wherever they match a defined user or group id, and have COPY, MOVE and REMOVE generate commands accordingly.

MSG= *list*
MESSAGE=*list*
A single decimal message number or a list of decimal message numbers enclosed in parentheses and separated by commas can suppress messages CKR*nnnn* where *nnnn* is the decimal message number. Besides suppressing the message output, this also suppresses processing of the return code associated with the message. Hence, the use of this option to suppress a critical error message that would terminate the program, might result in processing to be continued inadvertently, which can lead to abend conditions. The main use of this option is to suppress messages inherent to your configuration that you know about, but do not want to clutter your output with on each run. A large number of messages that would allow circumvention of restricted mode processing cannot be suppressed.

MSGTIMER
This parameter can be used to force display of all status messages in sequence, even though this causes response time to increase. This is mainly useful for automated testing programs.

MYACCESS< *level*
Limits REPORT and NEWLIST output to profiles that you might access at least the level indicated. The levels that can be used are listed with the ACCESS parameter of the REPORT command, see "REPORT" on page 875. As an example, SUPPRESS MYACCESS<ADMIN restricts REPORT and NEWLIST output to those profiles you may administer, for example profiles that are owner of, or discretes that you have ALTER access over. This keyword does not take system-wide privileges like system special into account, since otherwise it would make no difference whether the keyword was specified.

NOT_MY_LIST_SCOPE
This can be used to limit the profiles selected to those that fall within any scope specification including CKGLIST and AUDIT. The difference with SUPPRESS MYACCESS<ADMIN lies in the addition of profiles that can be reviewed due to CKGLIST scope or group-AUDIT authority.

RACF
Suppress the reading of the RACF database. This can only be used in unrestricted mode, and is useful if a NEWLIST is used that can make use of the RACF database, but does not require it. Typically, this is used in zSecure Audit for RACF.

REASON= *list*
Change REPORT SCOPE=, REPORT PERMIT=, or NEWLIST SCOPE=, reports to exclude profiles that would be included only for the reasons indicated. In restricted mode, the suppress reasons SELFCONNECT, PWDCHANGE, WARN, `NOPROFILE`, and `CKGRACMAP` are always set. Additional suppress reasons can be added as desired. See "Scoping rules that can be suppressed with REASON=" on page 938.

SETROPTSREFRESH
To suppress the generation of SETROPTS REFRESH commands.

SMF
Suppress the allocation of all SMF data sets. This can be used to prevent

unintended enqueues on and reads of the live SMF data sets while syntax checking a CARLa query. This is typically used when verifying an alert in IBM Security zSecure Alert.

SOFTEOF
Suppress soft end-of-file processing for ALLOC GETPROC routines. The soft end-of-file return code will be handled as a regular end of file.

UNIXCACHE
Suppresses the cache mechanism for the file path in calculating the effective file attributes (ATTR) for UNIX files.

VOL= *volser*
VOLSER=*volser*
VOLUME=*volser*
Suppress error messages relating to the specified volume. The volume is also ignored during resource copying and deletion. As a result, catalogs stored on the volume are also ignored which might make some cataloged data sets appear to be uncataloged and, as a result, scratched from the VTOC directly. (See 935.) If a Generation Data Group (GDG) is cataloged on this volume, neither the GDG or its Generation data sets (GDSs) residing on this volume are deleted. However, associated GDSs residing on other volumes might be considered uncataloged non-VSAM data sets and consequently scratched. VSAM components are never deleted separately. If you exclude one component, using the SUPPRESS option for example, you exclude the entire cluster.

Scoping rules that can be suppressed with REASON=

You can specify the following *list* values in the `SUPPRESS REASON=` *`list`* to suppress scoping rules:

ALTER-M
Suppress accesses that would be granted because users are permitted to modify certain fields of their own user profile ('alter myself').

CKGOWNR
CKGOWNER
CNGOWNR
CNGOWNER
Suppress accesses that would be included because access is granted through the CKGRACF authorized component of IBM Security zSecure Admin.

CKGRACMAP
Suppress access that is included because access through the CKGRACF authorized component of zSecure Admin is granted to FACILITY IRR.IDIDMAP.** resources.

CREATE
Suppress administrative access granted through CREATE authority on a connect and class authorization (CLAUTH) on a user.

GLOBAL
Suppress accesses that would be included because access is granted through the Global Access Table.

GRPAUDIT
GRPAUD
Suppress accesses that would be included because the user has the group-AUDITOR attribute.

GRPOPERATIONS
GRPOPER
Suppress accesses that would be included because the user has the group-OPERATIONS attribute.

GRPSPECIAL
GRPSPEC
Suppress accesses that would be included because the user has the group-SPECIAL attribute.

ID(*)
Suppress accesses that would be included because the access list grants access to the ID *, for example every RACF defined user.

NOPROFILE
UNPROTECTED
NOPROF
UNPROT
Suppress accesses that would be included because the data set or resource is not protected by a profile (in a NOPROTECTALL environment).

OWNER
Suppress accesses that would be included because (a) the user is owner of the profile; or (b) the first qualifier of a data set profile is equal to the user ID.

PWDCHANGE
PWD
Suppress accesses that would be included because another user ID, that is within the scope of the user, for example for which the password or password phrase can be set, is granted access on the access list, or is a direct owner.

SELFCONNECT
SELFCON
Suppress accesses that would be included because a group, that is within the scope of the user, for example to which the user can connect himself, is granted access on the access list.

UACC
UNIVACS
Suppress accesses that would be included because access is granted through the UACC.

WARNING
WARN
Suppress accesses that would be included because of profiles in warning mode.

Using the SUPPRESS command

The following examples show how to use the suppress command for different purposes. For an overview of the command, see "SUPPRESS" on page 932. For detailed information about the command options, see "SUPPRESS command options" on page 933.

Suppressing by volume: The following example shows how to suppress error messages for a dummy volume used for archived disk data sets.

```
suppress volume=migrat
```

Suppressing messages: The following example shows how to suppress error messages. This example suppresses the messages CKR072I and CKR073I.

```
suppress msg=(72,73)
```

Reducing scope output: The following example shows how to suppress common profiles in scope reports.

```
suppress reason=(global,uacc,id(*),warning,noprofile)
```

SYMBOLIC

The following information provides additions and corrections to the documentation for the LANGUAGE command which supports globalization of the zSecure product interfaces. This command is supported in the following zSecure products: Admin, Alert, Audit, Visual and the Tivoli Compliance Insight Manager Enabler for z/OS.

Use the SYMBOLIC command to define a symbolic name that can be used instead of a number. For example, you can use this command to define a symbolic name for a field length, a threshold specification, or a comparison against a numeric value in a SELECT statement. The symbolic name defined can be used directly as input during CARLa language processing (the CARLa input parse).

The following code sample shows the SYMBOLIC command syntax:

```
SYMBOLIC type  name=value
```

where

type
Specifies the type of symbolic. The only available type is NUM for numeric.

name=*value*
This parameter assigns a numeric value to the specified name which defines the *symbolic name*. The following syntax rules apply to the name=*value* specification.

- The name value cannot start with a digit (0 - 9, inclusive) and must contain at most 24 alphanumeric, national characters, or underscores.
- The *value* must be a base-10 (decimal) number. You cannot specify a hexadecimal (base-16) number.

During CARLa language processing, the symbolic name uses the assigned value until a SYMBOLIC statement with a matching name and type occurs in the input data. In the following example, the SYMBOLIC statement defines minvio=5. When the CARLa input parser encounters the summary statement, it interprets the *minvio* parameter as count (>5).

```
symbolic num minvio=5
...
summary ..  count(>minvio)
```

Multiple SYMBOLIC statements for the same name delineate the values used in the input parser. From the first definition of a symbolic name until the next definition for the same name, the assigned value is the one defined by the first SYMBOLIC statement. When a second SYMBOLIC statement with the same name is read, the value changes to the value specified in the second statement, and so on. For more information, see *Usage considerations*.)

The symbolic name can be used on its own or associated with a numeric default value as shown in the following example.

```
symbolic num minprio=40
...
select auditpriority>minprio|5
```

The default value is specified as `name|value` where *value* is a decimal number immediately following the vertical bar (|), without any spaces.

The vertical bar defines an OR relationship: Use the value from the SYMBOLIC statement if it is present, **or** use the default value from `name|value` if the SYMBOLIC statement is missing.

Usage notes

- You must define the symbolic name before the CARLa statement that references it. Otherwise, the definition is ignored.
- If the CARLa input processor expects a number or a symbolic name of type NUM for a `name`, and it encounters a non-numeric string that does not have a symbolic value defined, the following message is issued:
  `CKR1424: No numeric symbolic <name> found and no default at <ddname> line <line>.`
-

UNLOAD

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•	•	•	•	•	•	•

The UNLOAD statement can be used to write selected profiles or records. This statement can be used with the following types of data:

- RACF
- ACCESS
- SMF

The unload of SMF and ACCESS data requires that the UNLOAD statement is inside the scope of a NEWLIST statement.

If the ddname CKRUNLOU is allocated, the unload of RACF or ACF2 data is an automatic default action in Security zSecure. You can use the ALLOC statement or allocation of files CKRACF01 through CKRACF*nn* to specify the source of the security database records. When used outside the scope of a NEWLIST, the UNLOAD statement does not support any parameters or keywords.

Use of a NEWLIST statement and an explicit UNLOAD statement is preferred. Using an explicit UNLOAD statement has the following benefits.

- In an MVS system, an error message CKR0002 is issued if no CKRUNLOU file was found.
- In a CMS system, the file named "FILE CKRUNLOU A" is created automatically if no GLOBAL CKRUNLOU was defined.

An UNLOAD statement can also be specified in the scope of a NEWLIST. In this case, records of the applicable NEWLIST TYPE are unloaded and the ddname parameter is required on the UNLOAD statement.

When using UNLOAD, the following rules applies:

- An UNLOAD statement within the scope of a RACF or ACF2_* NEWLIST cannot be combined with the SCOPE= parameter on the NEWLIST statement.

- In restricted mode, SMF records must be within the scope of your authority. For CICS SMF 110 monitor records, this implies that the CICS region userid must be within your scope.
- When an UNLOAD statement is used within an ACCESS NEWLIST, the Access Monitor data is processed in parallel and is also consolidated.
- Unloading Access Monitor data is only supported for Access Monitor records in V1.13 format. Access Monitor records in V1.11 format cannot be processed using UNLOAD.

The UNLOAD command has the following parameters:

DDNAME=*ddname*
DD=*ddname*
FILE=*ddname*
F=*ddname*
Output file name for records selected by this NEWLIST.

COMPLEX= *name*
Unload records from this complex. If omitted, the complex of the default system is used. This parameter is supported only for RACF and ACF2_* NEWLIST types.

VERIFY

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	

The VERIFY command can be used to check the consistency of the database internally as well as in relation to resource data collected by zSecure Collect. Commands to remedy the shortcomings found are generated if the CKRCMD file has been allocated.

There is one option to invoke all VERIFY options at the same time. This might cause excessive memory and CPU usage on very large systems.

ALL
Select all analysis parameters that are entitled at the same time.

In addition, the sort order of the error messages and generated commands might be changed. This is often a good way to detect related events.

BY= *list*
Keywords indicating error message sort order. Change the sort order only for reporting purposes: it is not guaranteed that the commands generated will be in the proper order unless the default sort order is used. The messages are always first sorted by complex, before any of the BY parameters take effect. The complex name is not always printed with the messages. *list* is a list enclosed in parentheses with the keywords separated by commas indicating one or more of the following sort fields (the order given is the default sort order):

MSG
Message type. This is an internal value (not the message number) that will cause messages to be sorted by issuing function (like VERIFY PROGRAM or REMOVE PERMIT) . In addition, similar messages will appear in groups. If MSG is first in the sort order (default), the messages for each issuing function start on a new page with a header indicating the function. Some

commands call more than one function, causing the output to be split across the functions called (like VERIFY ALL or REMOVE USER).

VOL VOLUME VOLSER
Volume serial.

DSN DATASET
Data set name (resource name).

PGM PROGRAM PROG
Program name (with AC1, PADS,PROGRAM, PGMEXIST, and STC).

ID PERMIT
User or group (permit). In VERIFY STC: the started procedure name.

Security database without CKFREEZE

VERIFY CONNECT, CON

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	

Verify that the user, group, and connect profiles all provide the same connect information. No commands are generated to remedy the situation.

VERIFY GROUPTREE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	

Verify that there are no loops in the group ownership structure in the database, e.g. group A owns group B owns group C owns group A... No commands are generated to remedy the situation, but the complete ownership loop is printed. A loop where user A owns group owns user A is *not* detected.

VERIFY PADS

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	

Verify the protection of programs in a conditional access list. Since z/OS 1.4, RACF can run in 3 program control modes: Basic, Enhanced-Warning and Enhanced. Basic program security is the default , and equal to pre-z/OS 1.4 RACF program security. Enhanced mode offers better security, but requires more work in setting up the PROGRAM profiles. See the RACF Security Administrator's Guide for more information about these modes.

For each mode, VERIFY PADS verifies different settings. In Basic mode it verifies if all programs used on conditional access lists have a matching PROGRAM profile. Running VERIFY PADS while running RACF in Enhanced-Warning mode or Enhanced mode verifies if all programs used on conditional access lists have a specific PROGRAM profile, and if such a profile has APPLDATA with 'MAIN' or 'BASIC'.

If a CKRCMD file is allocated, commands are generated to fix any problems found by the verify. Again, for the different modes, the generated commands are different. Beside fixing any problems in the settings, the generated commands can

help with converting from Basic program security to Enhanced program security. Below is an explanation on how to do this.

Before converting to Enhanced program security, first run VERIFY PADS while in Basic security mode. Commands are generated to delete conditional access list entries without a corresponding program profile. After review, run these commands. This should do no harm to your system because these entries would not give access anyway.

Put your system in Enhanced-Warning mode, or put SIMULATE RDEF FACILITY IRR.PGMSECURITY APPLDATA('ENHWARN') in the job or preamble (SE.3), and run VERIFY PADS again. The commands that potentially do damage to your system's settings are generated as comments. You have to decide which of the commands need to be uncommented. Read the RACF Security Administrator's Guide for more information.

- If a specific program profile is found for the WHEN-program but this profile does not have APPLDATA with 'MAIN' or 'BASIC', the program will generate a commented command to add APPLDATA('MAIN') on the specified program profile. You can uncomment the line if the program is a MAIN program. If the program should be a BASIC program, uncomment and change MAIN to BASIC. If the program is not needed anymore on the conditional access list, keep the command commented. This will result in having the conditional access list entry deleted when running VERIFY PADS in Enhanced mode.
- If no specific program profile is defined, but a non-specific match is found, the program will generate commands to copy the non-specific profile to a specific one, including the member list. Furthermore, the program adds APPLDATA('MAIN') to the profile. This series of commands (starting with an RDEFINE followed by indented RALTERs) must be uncommented if the program needs to be a MAIN or BASIC program. Change the second RALTER accordingly. Keeping the lines commented results in deletion of the conditional access list entry when running VERIFY PADS in Enhanced mode.
- If no non-specific profile is found for the WHEN-program, the program will generate commands to delete the conditional access list entry. If the VERIFY PADS run in Basic program security returned no messages, this situation will not occur.

After selecting which programs need to run in MAIN or BASIC security and uncommenting the appropriate generated commands, let RACF run in Enhanced-Warning mode for a while. Doing this will point out any problems that still exist with the configuration (like the need for additional programs on conditional access lists and program profiles with APPLDATA('MAIN') or APPLDATA('BASIC')).

When you are happy with the new configuration and RACF in Enhanced-Warning mode has been running warning-free for a while, put RACF in Enhanced program security mode. Run VERIFY PADS once more to delete all conditional access list entries that do not have a specific program profile with APPLDATA('MAIN') or APPLDATA('BASIC').

For more information about the messages you get while running VERIFY PADS and its associated commands, see the *IBM Security zSecure: Messages Guide*.

VERIFY PASSWORD

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
				•		

The VERIFY PASSWORD command checks the RACF database for hashed passwords and weak (easy to guess) DES-encrypted passwords. The results of a disassembly of the ICHDEX01 password encryption exit are taken into account (e.g. no DES-encryption is performed if all systems use hashing).

The VERIFY PASSWORD command does not work using an unloaded RACF database, since an unload does not contain encrypted passwords (or similar sensitive fields). Instead, a 'real' RACF database (a primary/back-up database, or a copy) is required. If the VERIFY PASSWORD command is used with an unloaded database, message CKR0590 is generated.

The VERIFY PASSWORD command does not compromise the weak passwords found; it lists the users that have a weak password, but does not list the passwords themselves. It generates messages CKR0584 through CKR0589.

The VERIFY PASSWORD command does not generate commands to correct any weak passwords found, because this is very much dependent on the security policy of the system. Some suggested actions are:

- Contact the user and ask him to change the password.
- Revoke the user.
- Change the password of the user.
- Expire the password of the user, so that the password must be changed a the next logon.
- Change the password policy of the installation: introduce a new-password exit, establish password rules, or set a strict password interval.
- Start auditing the user to check for suspect activity.

Instead of generating commands, the VERIFY PASSWORD command generates a query in the CKR2PASS file that can be used to select the user IDs with weak passwords. This query can be edited to report on the user IDs, or to generate commands as desired. You must then run Security zSecure again, using the edited query as input.

Note: We advise you to send the user *no email* notifying him of a weak password, or to notify the user in any other way using a computer system. If the email were to be read by hackers or eavesdroppers, this would seriously compromise the security of the system. Contact the user by telephone or using regular mail.

Security database with or without CKFREEZE

Use the `VERIFY PERMIT` action to report on the security database with or without a `CKFREEZE` file.

If the RACF database is part of a multi-system RRSF configuration and a CKFREEZE file is supplied along with the RACF databases for the other RRSF connected systems, then the VERIFY PERMIT command attempts to verify that a userid that is undefined on the current system is undefined on all the RRSF connected systems. If the userid is found to be defined on at least one other system in the RRSF configuration, then no commands are generated to cleanup the

references to the userid on the current system unless the ONLYAT option is specified. See "ONLYAT" on page 863 in the OPTION command documentation.

VERIFY PERMIT, PERM

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	

Verify that each of the following is defined as a user or a group:

- ID entry in a standard or conditional access list
- owner
- RESOWNER
- NODES member
- superior group
- notify field
- STUSER and STGROUP specification other than =MEMBER in a profile with a generic first qualifier and certain APPLDATA fields

Also verify that users in keys of specially defined profiles (JESJOBS CANCEL.node.*userid*.jobname, for example) and data set profiles exist. This check pertains to the following classes:

- DATASET
- DLFCLASS
- CICS: TCICSTRN, GCICSTRN, DCICSDCT, ECICSDCT, FCICSFCT, HCICSFCT, ACICSPCT, BCICSPCT, JCICJCT, KCICSJCT, MCICSPPT, NCICSPPT, PCICSPSB, QCICSPSB, SCICSTST, UCICSTST, CCICSCMD, VCICSCMD
- FACILITY
- INFOMAN
- JES: JESJOBS, JESSPOOL
- LFSCLASS
- NODES
- PROPCNTL
- PTKTDATA
- STARTED
- SURROGAT
- TMEADMIN
- VM: VMCMD, VMRDR, VMBATCH, VMCONECT, VMEVENT, VMXEVENT

If the CKRCMD file has been allocated, commands are generated for the following:

- Delete permits, NODES members and profiles, STARTED user, groups and profiles that refer to non-existing ids.
- Change those OWNER, RESOWNER, NOTIFY, SUPGROUP and verified APPLDATA fields that refer to non-existing ids.

If a CKFREEZE is supplied, resource deletion is implied as well. That is, the data sets covered by the profiles are removed as well. (See "REMOVE" on page 870 and "SUPPRESS" on page 932 for details). The VERIFY PERMIT command is mutually exclusive with the COPY, MOVE, or REMOVE commands.

No commands and CKR0026 messages will be generated to change non-existing connect owners if SUPPRESS CONNECTOWNER has been specified. The reference count for undefined ids in message CKR0068 is **not** altered; undefined connect owners are still counted here.

Security database with CKFREEZE

VERIFY ALLNOTEMPTY, ALLNONEMPTY

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	

For a z/OS system, verify that all generic data set profiles cover real data sets. In addition to the NOTEMPTY option, profiles for which *no* less specific profile exists might also be flagged. If the CKRCMD file has been allocated, commands are generated to delete the empty profiles. If you have ABR configured to keep profiles, you are well advised to check if such an "empty" generic profile would cover a migrated non-VSAM data set if the assumption that it is RACF indicated on the migration tape turns out to be false. A CKFREEZE file is required.

This command supports RRSF configurations as follows:

- If the zSecure ONLYAT option **is not** specified, CARLa suppresses the generation of RACF commands that, if redirected, would cause deletion of a data set profile that covers existing data sets.
- If the zSecure ONLYAT option **is** specified, CARLa generates the DELDSD command that otherwise would have been suppressed and adds the ONLYAT parameter to generated RACF commands that should not be redirected; for example, commands that, if redirected, would cause deletion of a data set profile that covers existing data sets.

VERIFY DATASET, ONVOLUME, ONVOL

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	

For a z/OS system, verify that each discrete profile has a corresponding RACF indicated data set. If ABR is configured to keep profiles, a non-VSAM data set migrated by it is assumed to be indicated. If the CKRCMD file has been allocated, commands are generated to delete the misleading (because unused) discrete profiles. A CKFREEZE file is required.

VERIFY INDICATED,IND

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	

Verify that data sets with the RACF indicated bit on in the VTOC (non-VSAM) or catalog (VSAM) have a corresponding discrete DATASET profile, even if they seem to be covered by a generic profile. If the CKRCMD file has been allocated, commands are generated to first add discrete profiles with an access list that is a copy of the generic profile found (through use of the FROM parameter), and then delete the discrete profiles just created. This effectively removes the indicated bit. A CKFREEZE file is required.

Warning

The commands might be difficult to execute because commands involving the RACF indicated bit require en exclusive enqueue on the data set name. This is impossible to achieve for system data sets that are permanently enqueued.

For data sets migrated by ABR this verification is not performed in the current version of the product; if a non-VSAM data set had the RACF indicated bit set on migration, ABR will request a default discrete profile to be created via ADSP when the data set must be recreated on restore; migration of a VSAM data set does not preserve the RACF indicated bit.

VERIFY NOTEMPTY, NONEMPTY, GENERIC, GEN

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	

For a z/OS system, verifies that generic profiles of the DATASET class are not empty, meaning that profiles protect existing data sets.

For a z/OS system, verify that generic DATASET profiles that are also covered by a less specific generic profile are non-empty, for example data sets exist that are covered by the generic profile. This is meant to remove obsolete generic profiles. You should be aware that profiles intended to prevent or allow *allocation* in a PROTECTALL environment (in a way that differs from the less specific profile) is also flagged as empty, while it might not be your intention to remove these profiles. [8] You might want to include SIMULATE SETROPTS TAPEDSN in preparation of setting this option, if it is currently not active or if the tape management system issues DASD-type checks. If the CKRCMD file has been allocated, commands are generated to delete the empty profiles. A CKFREEZE file is required.

This command supports RRSF configurations as follows:

- If the zSecure `ONLYAT` option **is not** specified, CARLa suppresses the generation of RACF commands that, if redirected, would cause deletion of a data set profile that covers existing data sets.
- If the zSecure `ONLYAT` option **is** specified, CARLa generates the DELDSD command that otherwise would have been suppressed and adds the `ONLYAT` parameter to generated RACF commands that should not be redirected; for example, commands that, if redirected, would cause deletion of a data set profile that covers existing data sets.

Warning:

Do not execute commands generated with an incomplete `CKFREEZE`. That is, a `CKFREEZE` made by a non-APF run of zSecure Collect. This will miss relevant VSAM information and will cause removal of profiles that cover (only) VSAM data sets. You are alerted to such dangers by the messages in the VSAM OR VVDS INCONSISTENCIES section of the output. Data

8. | For instance because the data sets have been archived, or because you have ADSP active, or because they are used for tape data sets, and the CKFREEZE file did not contain the relevant information.

sets mentioned in this section are usually not assigned to any profile because relevant information to do so reliably was missing.

VERIFY PGMEXIST, PROGRAMNONEMPTY, PROGRAMNOTEMPTY, PGMNONEMPTY, PGMNOTEMPTY

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	

Verify that each PROGRAM profile covers at least one load module. To be covered by a profile, the name of the load module must match the pattern set by the profile key, and the load module must reside in a data set that is a member of the profile. If the CKRCMD file has been allocated, commands are generated to remove PROGRAM profiles that are not matched by any member or alias in any of the data sets in its member list.

If important information to decide whether there is a match is missing, the removal command is generated, but commented out. Messages in the SYSPRINT indicate why a certain decision was made. The messages are explained in detail in the *IBM Security zSecure: Messages Guide*.

To make sure the CKFREEZE file provides the appropriate information, follow these guidelines:

1. Include VTOCs for important volumes in a CKFREEZE data set so that zSecure knows what data sets reside on them. If you use DASD sharing, make sure that the set of CKFREEZEs for this complex contain the VTOCs of all DASD.

   For performance reasons, it is common to avoid duplicate VTOC information (in multiple CKFREEZE data sets) by running zSecure Collect with `SHARED=NO` on all except one of the z/OS images that share a set of DASD volumes. However, when a volume is shared among some, but not all of your z/OS images, and you run the CKFREEZE with `SHARED=YES` on an image that does not have access to that volume, that volume will be missing in the combined CKFREEZEs. The program's analysis is most reliable when analyzing all systems that share the RACF database at the same time.
2. When automatic migration is active, include the migration catalog in the CKFREEZE so that zSecure Admin and zSecure Audit know which data sets are migrated. Make sure you do not suppress the collection of these catalogs by specifying (`MCD=YES`, `DMS=YES`, or `ABR=YES`). In addition, make sure that zSecure Collect knows about the correct data set (`HSMMCD=`, `DMSFILES=`, or `ARCDSN=`).

   If a sensitive data set has been migrated, zSecure cannot get the PDS directory of the data set. For reliable analysis, recall the data set.
3. Include PDS directory dumps in a CKFREEZE data set so that zSecure Admin and zSecure Audit know what load modules are present in the PDSes. To ensure this, consider the following guidelines:
   a. To make sure PDS directories are dumped, run zSecure Collect with `FOCUS=AUDIT` or `FOCUS=RACF`.
   b. To automatically dump sensitive data sets such as APF and linklist libraries, run zSecure Collect APF-authorized.

      If zSecure Collect runs unauthorized, these sensitive data sets are not dumped automatically to avoid causing a large number of 913-38 abends. To override this default behavior, set `PDS=YES`. The user ID that runs the program must have READ access to the data sets.

c. To configure zSecure Collect to dump specific data sets, use PDSDIR=*dsname* statements. If the program does not run APF-authorized, you must ensure that the execution user ID has at least READ access to the data sets.

Note: It might be necessary to first resolve all conditions identified by VERIFY PROGRAM , for example, in case a data set moved to another volume.

VERIFY PROGRAM, PGM

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	

Verify that each data set/volume combination added as a member to a PROGRAM profile indeed refers to a valid partitioned data set. If the CKRCMD file has been allocated, commands are generated to remove the invalid data set/volume combinations from the PROGRAM profile.

If a VTOC or migration catalog that is required to decide whether there is a match is not found in the CKFREEZE file(s), the removal command is generated, but commented out. Messages in the SYSPRINT indicate why a certain decision was made. For more information about the messages, see *IBM Security zSecure: Messages Guide*. See VERIFY PGMEXIST for an explanation how to ensure all VTOCs are present for analysis.

Note: Running VERIFY PROGRAM might not be the only action needed to "fix" PROGRAM profile settings. You might have to manually add a new data set/volume combination to the profile if the data set was moved to another volume.

VERIFY PROTECTALL, PROT

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	

VERIFY PROTECTALL verifies that all DASD data sets (including migrated data sets, as these will be recalled when allocating) are covered by at least one DATASET profile. In accordance with RACF, a generic profile is always considered sufficient (if the name matches), discrete profiles are only considered applicable to RACF-indicated data sets. An exception is made for ABR-migrated data sets, as the RACF-indicated flag can only be inspected by reading the migration tape. For these data sets, discrete profiles will be considered applicable if the ABR PROFKEEP option is active (which is unusual).

In a PROTECTALL(FAILURES) environment, data sets without a profile are inaccessible, in a NOPROTECTALL environment such data sets are unprotected. RACF-indicated data sets without discrete or matching generic profile are always inaccessible.

For RACF-indicated data sets without discrete or matching generic profile, an ADDSD command to create a discrete profile is generated. Note that most of the time this is not what you want; it is better to define a generic profile and PERMIT the groups requiring access. Generated commands are written to the CKRCMD file.

VERIFY SENSITIVE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
				•		

The VERIFY SENSITIVE command verifies the RACF-protection of system-sensitive data sets and generates RACF commands to adjust the protection. This command generates messages CKR0473 to CKR0485.

The VERIFY SENSITIVE is a companion to the sensitive data set report and the REPORT SENSITIVE command. The Sensitive data set report provides infomration on system-sensitive data sets. The REPORT SENSITIVE command reports on the RACF-protection of system-sensitive data sets.

Note: The sensitive data set report is also of use in non-RACF systems. The REPORT SENSITIVE and VERIFY SENSITIVE commands are not useful in non-RACF systems.

The VERIFY SENSITIVE command checks all RACF system-sensitive data sets to determine whether they are protected by a RACF profile, have the appropriate audit level defined or implied by LOGOPTIONS, SECLEVELAUDIT, or SECLABELAUDIT settings, and have the UACC and the access of ID '*' set at the appropriate level. If the protection is not adequate, commands are generated to update the protection. The generated commands update the RACF-protection in the following manner:

- Unprotected data sets are protected by a fully qualified generic profile with the appropriate UACC and audit options.
- Data sets inadequately protected by a fully qualified generic or discrete profile have their profile adjusted.
- Data sets inadequately protected by a generic profile get a new fully qualified generic profile, copied from the current generic profile. The new profile is then adjusted. In this manner, the access list, installation data, and other information from the old profile are preserved.

The VERIFY SENSITIVE command adheres to the CS-1 (Commercial Security 1) protection profile from the U.S. Federal Criteria and the Common Criteria V1.0 (currently a draft ISO standard). This is roughly equivalent to the C2 level of the orange book (see “SIMULATE” on page 911).

VERIFY STC

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	

Verify the consistency of Started Procedure Table ICHRIN03 and the RACF STARTED class with the RACF user and group definitions, and with the procedure members of the JES2/JES3 and MSTR procedure libraries used for started tasks. The following conditions are flagged for ICHRIN03: non-startable procedures, procedures unable to use the user or group indicated by ICHRIN03, obsolete ICHRIN03 entries, protection deficiencies, hidden procedure members, and procedures running with the default RACF user '*' for various reasons. The following conditions are flagged for the RACF STARTED class: invalid or incomplete STARTED profiles; STARTED profiles not used by any procedure; procedures unable to use the correct STARTED profile and using user '++++++++'; procedures that do not match any STARTED profile and use ICHRIN03 instead. To

omit messages for the default user ID, add SUPPRESS ID=* or SUPPRESS ID=++++++++ [9] VERIFY STC is mutually exclusive with COPY, MOVE and REMOVE commands.

The following errors will be corrected or at least made more explicit if they occur on the profile level (that is, they are not the result of evaluating an =MEMBER specification for a started task matching a profile with a generic first qualifier): no STDATA segment, invalid STUSER, invalid STGROUP. For the first, an STDATA segment with an STUSER specification of =MEMBER will be generated if the first qualifier is a valid user ID, or NOUSER otherwise; invalid specifications will be either be corrected to =MEMBER or made more explicit by deleting them. The following errors will only be flagged: no connection between user and group, user ID revoked, errors on the member level. As much as possible, multiple error conditions are combined into one message, except that errors on the member level are not reported when an error message on the profile level is issued.

VERIFY TSOALLRACF

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
				•		

The VERIFY TSOALLRACF verifies that all users defined in the UADS data set are defined to RACF and have a TSO segment. It generates messages CKR0580 and CKR0581.

Users that are defined in the UADS data set, but not defined to RACF, are not subject to RACF password and revoke controls. Users that are defined in the UADS data set, are defined to RACF, but do not have a TSO segment, take their TSO attributes from the UADS data set. In both cases, the RACF administrator cannot properly control the TSO user.

Example - combining verifications

This example shows a combination of verification options that you could use for a periodical 'health-check' on your database.

```
verify program pads pgmexist protectall onvolume permit connect stc
```

Example - verifying started tasks

This example shows how to check the started task scene while suppressing messages for started tasks running with a default user ID.

```
verify stc
suppress id=*
```

9. If you have changed the JES undefined user from '++++++++' to something else, you should use the actual value on the suppress statement. This value is contained in the UNDEFINEDUSER field of NEWLIST TYPE=SYSTEM, which is reported in the SETROPTS report in “SETROPTS - RACF settings report” on page 266 under the heading "Job Entry Subsystem options" as "Default uid local UNDEFINEDU".

Chapter 13. SELECT/LIST Fields

This chapter provides information on the NEWLIST fields for selecting data and creating zSecure reports. Each NEWLIST type can be used to generate reports on a specific type of information. For example, the SYSTEM NEWLIST provides information about system-wide option settings. Each NEWLIST type has a set of fields that can be used in SELECT, EXCLUDE, and LIST statements for reporting about the specified information. For additional information on each NEWLIST type, associated fields, and usage notes, see the following sections.

ACCESS: Access Monitor Records

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•			

Use the NEWLIST TYPE=ACCESS for viewing and reporting on access information in the records collected by the zSecure Access Monitor. You can also use this NEWLIST to filter or summarize the information in the Access Monitor data sets.

The most common application is viewing and reporting on monitoring information. If you use the ACCESS NEWLIST to filter or summarize Access Monitor data sets, make sure that the output Access Monitor data set has the same layout and format as the input Access Monitor data set. For example, one of the requirements is to specify OPTION NULLS to avoid translating null (x'00) characters into blanks (x'40') in the output.

You can use most ACCESS NEWLIST fields for the following functions:

- Select and exclude information in a query with the SELECT and EXCLUDE commands.
- Generate output with the following output commands (LIST, SORTLIST, DISPLAY, and (D)SUMMARY.

Not all fields are available in all records. For example, many fields are not available on START and STOP records. If a field has restrictions, the restriction is noted in the field documentation. See "Field descriptions" on page 954.

The ACCESS NEWLIST supports two different formats of Access Monitor data sets. The first format is the one used in zSecure V1.12 and earlier releases. It is referred to as the V1.11 format. The second format is the one used in zSecure V1.13 and later releases. It is referenced to as the V1.13 format. Use of the V1.13 format allows use of the UNLOAD statement to perform fast consolidation of Access Monitor data sets. When using the UNLOAD statement to consolidate multiple Access Monitor data sets, all input data sets must be in V1.13 format. When not using an UNLOAD statement, a combination of V1.11 format and V1.13 format data sets can be used. Within a single NEWLIST, the UNLOAD statement cannot be combined with any other statement.

For more information about the Access Monitor data and the zSecure Access Monitor program, see Chapter 10, "RACF Access Monitor," on page 643.

Field descriptions

The ACCESS NEWLIST provides the following fields for reporting.

ACCESS_ALLOWED

Describes the allowed access. The value of the field depends on the RACROUTE REQUEST macro issued:

- For auth-type records (RECTYPE=AUTH), the ACCESS_ALLOWED field indicates the System Authorization Facility (SAF) access level allowed by RACF.
- For fastauth-type (RECTYPE=FAST) and define-type (RECTYPE=DEF) records, the ACCESS_ALLOWED field is not used and always has a value of *NONE*.

This field is not available for START and STOP records.

ACCESS_COUNT

Shows the number of RACROUTE requests of this type. The default format for this 32-bit number is UDEC, which might need up to 10 characters to show its value correctly. To accommodate narrower columns, the overriding output format UDEC$ABBR can be used. For numbers larger than 4 294 967 296, the field ACCESS_COUNT_BIG might be available. For creating V1.11 format Access Monitor records, use the ASIS output format. For creating V1.13 format Access Monitor records, use the ACCESS_COUNT_BIG field instead.

This field is not available in START and STOP records.

ACCESS_COUNT_BIG

Shows information similar to that shown for the ACCESS_COUNT field. The internal format of this field is a 64-bit number, which accommodates values up to 20 decimal digits. The default format for this 64-bit number is UDEC. If the number does not fit in the specified column width, asterisks are shown. To accommodate narrow columns the overriding format UDEC$ABBR can be used. For large numbers, the UDEC$ABBR format might also be easier to read. For creating V1.13 format Access Monitor data sets, use the ASIS output format.

This field is not available in START and STOP records.

ACCESS_FLAGS_RAW

This unformatted field contains bits that provide information about access request results, for example, a bit that indicates if an ACCESS_PROFILE is a generic or discrete profile. To display or report on this field, use the overriding format of (HEX,4).

This field is not available for START and STOP records. The ACCESS_FLAGS_RAW field summarizes the information that is provided in the individual ACCESS_* fields in the ACCESS NEWLIST in an unformatted bit field. To provide output in a more readable format, use the individual ACCESS_* fields to select and list the information instead of using this summary field.

ACCESS_GENERIC

This flag field (YES/NO) indicates whether the profile that was used to determine access privileges is generic or discrete. This field is not available for START and STOP records.

ACCESS_GLOBAL

This flag field (YES/NO) indicates whether the access request was granted using the global access checking (GAC) table. The ACCESS_GLOBAL value is based

on the actual processing by RACF. If an application requested a profile to be returned (reported by the "REQ_PRIVCSA" on page 959 flag), the ACCESS_GLOBAL flag value is NO.

This field is not available for START and STOP records.

ACCESS_IS_GROUP

This flag field (YES/NO) indicates if the userid used for the access request represents a RACF group. This situation occurs most often during access requests for DFP resources such as MGMTCLAS where access by the RESOWNER of the data set is checked. This field is not available for START and STOP records.

ACCESS_OPERATIONS

This flag field indicates that OPERATIONS authority, either group-OPERATIONS or system-wide OPERATIONS, was used to grant access. It is not possible to determine from this field if the RACF attribute was system-level or group-level. For DEFINE-type events, the field indicates whether OPERATIONS authority was used to define or delete a resource or profile. This field is set only if the RACF level supports it. For RACF releases that do not provide this data, Access Monitor records show a value of either No or missing depending on whether a CKFREEZE file was provided. See also "ATTRIB_OPERATIONS" on page 956.

ACCESS_PRIVTRUS

This flag field (YES/NO) indicates whether the address space issuing the access request has the Privileged or Trusted attribute. For RACROUTE REQUEST=AUTH macro requests (rectype=AUTH) issued from an address space that has either attribute (ACCESS_PRIVTRUS = YES), access is granted immediately without retrieving a profile. If the application also specifies that a profile be returned–reported by the "REQ_PRIVCSA" on page 959 field, then the privileged and trusted attributes are ignored by RACF.

Starting with z/OS 1.11, the privileged and trusted attributes are also honored by RACF and reported by the zSecure Access Monitor program for RACROUTE REQUEST=FASTAUTH macro requests (rectype=FAST).

The ACCESS_PRIVTRUS value is also reported for RACROUTE REQUEST=DEFINE(rectype=DEF) but is ignored by RACF. This field is not available for START and STOP records.

ACCESS_PROFILE

The profile name that was used for the resource specified in the RACROUTE call. When writing Access Monitor data sets, use the L1CHAR output format.

Although most auth-type and define-type records contain a profile name, the ACCESS_PROFILE field might be missing under certain conditions. Some aspects of this profile are output by the field "ACCESS_FLAGS" on page 954.

This field is not available in START and STOP records.

ACCESS_PROFTYPE

Indicates the type of profile that was used to grant or refuse the access. If no profile was used, the value returned can be either missing if there was no profile involved, or qualown if access was granted based on ownership of the resource key qualifier that determines ownership. For class DATASET, the value is the HLQ (High-level qualifier), which is the first qualifier as changed by any naming convention tables or exits.

Table 319. Access Profile Types for NEWLIST TYPE=ACCESS

Access profile type	Description
DISCRETE	Discrete general resource profile record.
GENERIC	Generic data set or general resource profile record.
GLOBAL	Global access table entry record.
missing	This value is returned when RACF did not use a profile for its decision, or if the profile could not be found.
MODEL	Model profile record.
NONVSAM	Discrete non-VSAM DATASET profile record.
TAPEDSN	Discrete tape data set profile record.
VSAM	Discrete VSAM profile.
qualown	Access granted based on ownership of the resource key qualifier that determines ownership. For the DATASET class, this value is the HLQ (High-level qualifier).

ACCESS_RESULT

Specifies the return code from the RACROUTE call, including the effects of PROTECTALL and the default return code for the class. For define-type records, the value is always zero even if the DELETE or DEFINE request is failed by RACF.

The ACCESS_RESULT field is not available for START and STOP records.

ACCESS_SPECIAL

This flag field indicates that SPECIAL authority was used to grant access. For example, the system-SPECIAL attribute might have been used to access a data set that has no RACF profile while PROTECTALL was active. For DEFINE-type events, the field indicates whether SPECIAL authority was used to define or delete a profile. This field is set only if the RACF level supports it. For RACF releases that do not provide this data, Access Monitor records show a value of either No or missing depending on whether a CKFREEZE file was provided. See also "ATTRIB_SPECIAL."

ACCESS_UNDEFINED_USER

This flag field (YES/NO) indicates whether the userid is RACF defined. This field is not available for START and STOP records.

ACCESS_USED_EXIT

This flag field indicates whether an installation exit was used to grant or deny the requested authorization. The field is present for AUTH and DEFINE records only, and is reported as missing for all other record types, including FAST. This field is set only if the RACF level supports it. For RACF releases that do not provide this data, Access Monitor records show a value of either No or missing depending on whether a CKFREEZE file was provided.

ATTRIB_OPERATIONS

This flag field indicates that the user's ACEE had the system-wide OPERATIONS bit set at the time of the access authorization. This value can reflect the attribute setting in the RACF database or reflect the temporary setting of the OPERATIONS bit by other programs to increase their authority.

ATTRIB_SPECIAL

This flag field indicates that the user's ACEE had the system-wide SPECIAL bit set at the time of the access authorization. This value can reflect the attribute setting in the RACF database or reflect the temporary setting of the OPERATIONS bit by other programs to increase their authority.

CLASS

Specifies the class name of the requested resource.

The field is not available for START and STOP records.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

Identifies the security complex of the system where this file originated. The value is derived from the system name in the SYSTEM field for the Access Monitor record, the `ALLOC COMPLEX=` specification for the Access Monitor file, and the systems and database allocations. The default field length is eight characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or zero. See "Modifying output length" on page 797.

DDNAME

Specifies the DDNAME of the $zsecures; ACCESS input file.

FLAGS_RAW

This is an unformatted field containing the flag bits that describe parameters on the RACROUTE request such as the RACFIND setting of a data set. To display and report on this field, use an override format of (HEX,2).

This field is not available for START and STOP records. For most applications, it is a good idea to use the individual REQ* fields instead of the FLAGS_RAW field.

INTENT

Describes the requested access. The value of the field depends on the RACROUTE REQUEST issued:

- For auth-type records (`RECTYPE=AUTH` and `RECTYPE=FAST`), the INTENT field value indicates the System Authorization Facility (SAF) access level requested. Possible values are READ, UPDATE, CONTROL and ALTER.
- For define-type records (`RECTYPE=DEF`), the value shows the type of DEFINE request. Possible values are `DEFCREA`, `DEFDELE`, `DEFCHGV` and `DEFADDV`.

The field is not available for START and STOP records.

INTENT_RAW

Describes the requested access in a one-byte bit-field. The value of the field depends on the RACROUTE REQUEST issued:

- For auth-type records (`RECTYPE=AUTH` and `RECTYPE=FAST`), the value represents the System Authorization Facility (SAF) access level requested.

- For define-type records (RECTYPE=DEF), the value represents the type of request: DEFINE, DELETE, ADDVOL, or CHNGVOL.

The field is not available for START and STOP records.

JOBNAME

Shows the name of the task where the access monitor event occurred. This field is reported as missing if the input record does not contain the field. For most ACCESS files, the JOBNAME field is present only for those userids for which the JOBNAME field has been activated in the C2PAMJOB customization member. The primary use of the JOBNAME field is with shared userids, such as those used in some job scheduling implementations, or those used for started tasks. For customizing the C2PAMJOB member, see Chapter 10, "RACF Access Monitor," on page 643.

LAST_TOD

The time of day (UTC) that the specific event last took place.

RECNO

Specifies the record number of the current record within its input file. The RECNO field applies to the number of complete logical records within a single input file, counting the first record as 1.

RECORD

Specifies the current record from the Access Monitor file. This field is mainly for debugging purposes.

RECORDLENGTH

Provides the length of the Access Monitor record in bytes, excluding the RDW, the first four bytes at the start of a variable record length file. The given length is the one of the logical record.

RECTYPE

Describes the type of record. Table 320 lists the possible values

Table 320. RECORD Types for NEWLIST TYPE=ACCESS

Value	Description
Start	START record marking start of interval.
Stop	STOP record marking end of interval.
Auth	AUTH - RACROUTE REQUEST=AUTH
Fast	FAST - RACROUTE REQUEST=FASTAUTH
Define	DEF - RACROUTE REQUEST=DEFINE

REQ_CHECKAUTH

This flag field (YES/NO) indicates whether the RACROUTE REQUEST=DEFINE macro requested that RACF perform an internal RACROUTE REQUEST=AUTH. This function is intended to be used by the RACF command processors.

This field is not available for AUTH, FAST, START, and STOP records.

REQ_COMMAND

This flag field (YES/NO) indicates whether the RACROUTE REQUEST=DEFINE macro is issued as the result of a RACF command.

This field is not available for AUTH, FAST, START, and STOP records.

REQ_GENERIC

This flag field (YES/NO) indicates whether the application that called the RACROUTE REQUEST=AUTH or RACROUTE REQUEST=DEFINE macro explicitly requested that RACF considers the resource name as a generic profile name. This function is normally only used by the RACF command processors.

This field is not available for START and STOP records.

REQ_PRIVCSA

This flag field (YES/NO) indicates whether the application that called the RACROUTE REQUEST=AUTH macro requested that RACF return a profile in the Private area or in CSA. When this flag is set, RACF ignores the GAC table and the Privileged and Trusted attributes. For FAST records, the REQ_PRIVCSA value is NO.

This field is not available for DEF, START, and STOP records.

REQ_PROPAGATED

This flag field (YES/NO) indicates whether the RACROUTE REQUEST=DEFINE macro is issued as the result of an automatic direction of application updates.

This field is not available for AUTH, FAST, START, and STOP records.

REQ_RACFIND

This flag field (YES/NO) indicates the value specified by the application that called the RACROUTE REQUEST=AUTH or RACROUTE REQUEST=DEFINE macro for the RACF Indicator. The flag field is missing if the application did not specify RACFIND.

This field is not available for START and STOP records.

REQ_RACFIND_SPECIFIED

This flag field (YES/NO) indicates whether the application that called the RACROUTE REQUEST=AUTH or RACROUTE REQUEST=DEFINE macro specified that the resource has a RACF Indicator. If the application specified RACFIND, the REQ_RACFIND_SPECIFIED value is YES. If the application did not specify RACFIND, the value is NO. The value of the RACF Indicator is reported in the "REQ_RACFIND" field.

This field is not available for START and STOP records.

REQ_VERIFY

This flag field (YES/NO) indicates whether RACROUTE REQUEST=DEFINE macro verifies the user's authority only or whether it also defines a profile in the RACF database.

This field is not available for AUTH, FAST, START, and STOP records.

RESOURCE

Shows the SAF (System Authorization Facility) resource specified on the RACROUTE call. Most define-type records and some auth-type records contain a resource name. When writing Access Monitor data sets, you should use the L1CHAR output format.

This field is not available for START and STOP records.

SIM_CLASS

Indicates the class where the profile used is located. Possible values are: Grouping-Class, Member-Class or Class.

SIM_GENERIC

A flag to indicate that this is a generic profile. The default output length for the field is 3. The default format is Yes or No.

SIM_PROFILE

The name of the profile in SIM_CLASS that is used for access verification according to the current RACF database.

SIM_PROFTYPE

Type of profile in the current RACF database. The field output length is 8. For the meaning of the values, see the table with `TYPE=RACF_ACCESS` field `PROFTYPE`.

SIM_RESULT

A numeric field that indicates if the user has access based on the access list for the current RACF database. The reported result takes into account the effect of the RACF `PROTECTALL` setting. `SIM_RESULT` can have any of the following values:

8 indicates a violation

0 indicates success

4 indicates an undetermined status.

SYSTEM

The system id as mentioned in the Access Monitor file or stream.

USERID

The user id as mentioned in the Access Monitor file or stream.

This field is not available for `START` and `STOP` records.

UTOKEN_POE

This field shows the Port of Entry (POE) of the task where the Access Monitor event occurred. This field is reported as missing if the input record does not contain the field. For most ACCESS files, the UTOKEN_POE field is present only for those events for which POE processing has been activated in the C2PAMPCL and C2PAMRCL customization members. The primary use of the UTOKEN_POE field is with events, where access is granted using the conditional access list, such as for resources in the OPERCMDS class. For customizing the C2PAMJPCL and C2PAMRCL members, see Chapter 10, “RACF Access Monitor,” on page 643.

UTOKEN_POECLASS

Shows the CLASS of the Port of Entry of the task where the Access Monitor event occurred. This field is reported as missing if the input record does not contain the field. For most ACCESS files, the UTOKEN_POECLASS field is present only for those events for which POE processing has been activated in the C2PAMPCL and C2PAMRCL customization members. The primary use of the UTOKEN_POECLASS field is with events, where access is granted using the conditional access list, like for resources in the OPERCMDS class. For customizing the C2PAMJPCL and C2PAMRCL members, see Chapter 10, “RACF Access Monitor,” on page 643.

UTOKEN_POE_RAW

Shows the Port of Entry, concatenated to its CLASS, of the task where the Access Monitor event occurred. The CLASS is represented by its internal format. This field is primarily intended for consolidation of ACCESS files. It is present for only those events for which POE processing has been activated in the

C2PAMPCL and C2PAMRCL customization members. For customizing the C2PAMJPCL and C2PAMRCL members, see Chapter 10, “RACF Access Monitor,” on page 643.

AUDIT: System setting audit concerns

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
				•	•	•

AUDIT NEWLIST type reports on the audit concerns raised by global option settings. Information about the global option settings is provided by the SYSTEM NEWLIST. The audit concerns reported might be affected by the SIMULATE POLICY setting.

Field descriptions

You can use the following fields to select and create audit reports for System settings.

AREA

The subsystem or area where this concern was detected MVS, SMF, HSM, DMS, SYSLOG, TSO, SETROPTS, and GSO. The default output length is 4, the actual field is 8 characters.

AREAPARM

Name of the setting or parameter within the AREA (as found in the PARMLIB or on the SETROPTS command). The field PARMNAME (when available) contains the name of the NEWLIST TYPE=SYSTEM CARLa field that describes the setting/parameter.

AUDITCONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field. The AUDITCONCERN field can contain one or more concerns separated by commas.

The following audit concerns have been defined regarding common concerns in the MVS area:

- Security/integrity flaw remediation no longer guaranteed

  The z/OS release is no longer in service with IBM. Hence security or integrity exposures will no longer be fixed. You should upgrade to a more recent version to get the benefits of flaw remediation. The end-of-service date supplied by IBM for your operating system release level is compared against the date that the CKFREEZE file was made. If no CKFREEZE file is used, the current date is taken. The release level checked is available as field MVSLEVEL in the SYSTEM NEWLIST.
- Non-APF Refreshable modules can be modified despite Binder REFR setting

  The REFRPROT facility is available on this system but is set off. As a result, modules that are marked as Refreshable (not expected to be modified) can be modified by problem-state programs running in normal user key. This is both a RAS (Reliability/Availability/Serviceability) risk and a minor security risk.

The following audit concerns have been defined regarding common concerns in the VM area:

- Security/integrity flaw remediation no longer guaranteed

The VM or z/VM release is no longer in service with IBM. Hence security or integrity exposures are no longer fixed Upgrade to a more recent version to get the benefits of flaw remediation. The end-of-service date supplied by IBM for your operating system release level is compared against the date the CKFREEZE was made. If no CKFREEZE is used, the current date is taken.

The following audit concerns have been defined regarding common concerns in the HSM area:

- Disk scavenging threat not countered in HSM: *HSMNAME*/ not C2 compliant

  HSM is not erasing the disk when it deletes a data set from DASD after migration. This enables an attacker to allocate the disk space vacated and read the contents of the data set that has been migrated. This is a direct violation of the C2 security policy.

The following audit concerns have been defined regarding common concerns in the SMF area:

- No audit trail at all

  SMF collection is not active, hence the official operating system audit trail is not being written. This means that there is no user accountability for activities on the system.

- Hacker can work unobserved after flooding audit trail / not C2 compliant

  The security setting LASTDS(HALT) is not active. This setting should be active to operate on the C2 level defined in the Orange Book. Companies often value availability higher than other security measures and hence allow malicious users the opportunity to do their evil work without an audit trail. The flag is also available through the SMFLASTDSHALT field in the SYSTEM NEWLIST.

- Hacker can work unobserved after flooding audit buffers / not C2 compliant

  The security setting NOBUFFS(HALT) is not active. This setting should be active to operate on the C2 level defined in the Orange Book. Companies often value availability higher than other security measures and hence allow malicious users the opportunity to do their evil work without an audit trail. The flag is also available through field SMFNOBUFFSHALT in the SYSTEM NEWLIST.

The following audit concerns have been defined regarding common concerns in the SYSLOG area:

- Part of audit trail missing

  The SYSLOG is not active. Although the SMF data sets form the primary audit trail, the JES SYSLOG is also of value to be able to trace back what happened in the system, especially during startup processing. Also, in practice, the SYSLOG often contains messages for events even though the SMF logging was being suppressed. The flag is also available as field SYSLOG_ACTIVE in SYSTEM NEWLIST.

- Operator command parms and responses not in syslog

  Normally the system would contain the parameter HARDCOPY DEVNUM(SYSLOG) in the CONSOLxx PARMLIB member. This is however not the case, causing the SYSLOG to be incomplete. The flag is also available as field SYSLOG_COMMANDS in SYSTEM NEWLIST.

- Operator command parms and responses undetectable

  the system contains HARDCOPY CMDLEVEL(NOCMDS) in the CONSOLxxPARMLIB member. This causes operator commands, system commands, and there responses to be missing from the hardcopy log. The command level setting is available through the CON_HCPY_CMDLEVEL field in the SYSTEM NEWLIST.

The following audit concerns have been defined regarding common concerns in the TSO area:

- VTAM buffers are not confidential

  The TSO or VTAM buffers might contain confidential information like passwords. To erase this information after use, the CONFTXT option in PARMLIB member TSOKEYxx can be set. Currently it is not set. The flag is also available through the TSOCONFTXT field in the SYSTEM NEWLIST.

The following audit concerns have been defined regarding RACF concerns in the SETROPTS area:

- Profile changes in USER class are not audited

  Reflects the SETROPTS AUDIT(USER) setting. This audit concern indicates that profile changes in the USER class are not logged to SMF for the following commands: ADDUSER, ALTUSER, CONNECT, DELUSER, PASSWORD and REMOVE.

  These profile changes *are* logged when SPECIAL users execute the commands while the SETROPTS SAUDIT setting is active. In addition, some USER class profile changes are also logged when SETROPTS AUDIT(GROUP) is enabled.

- Profile changes in GROUP class are not audited

  This audit concern reflects the SETROPTS AUDIT(GROUP) setting. It indicates that profile changes in the GROUP class are not logged to SMF for the following commands: ADDGROUP, ALTGROUP, CONNECT, DELGROUP and REMOVE.

  These profile changes *are* logged when SPECIAL users execute the commands while the SETROPTS SAUDIT setting is active. In addition, some GROUP class profile changes are also logged when SETROPTS AUDIT(USER) is enabled.

- ADSP is inefficient

  Automatic Data Set Protection is an option to automatically add a discrete DATASET profile each time a data set is being created by a user that also has ADSP set in his user profile or the current connect group. This is an old-fashioned way of protecting data. The combination of PROTECTALL(FAIL) with generic DATASET profiles is easier to maintain. The flag is available through the SETRADSP field in the SYSTEM NEWLIST.

- Password to switch RACF database still at IBM default

  Any user with access to a console with command authority, or an APF utility that can issue commands, can switch the system to a different RACF database because the password for this operation is still set to the IBM default. The flag is available through the RVARYSWITCHPWSET field in the SYSTEM NEWLIST.

- Password to deactivate RACF still at IBM default

  Any user with access to a console with command authority, or an APF utility that can issue commands, can switch off RACF because the password to issue the RVARY STATUS command is still to the IBM default. This flag is available through the RVARYSTATUSPWSET field in the SYSTEM NEWLIST.

- Allowing unidentified batch work makes hacking easy / not C1 compliant

  The SETROPTS JES(NOBATCHALLRACF) setting for this system allows jobs to run without RACF identity and authentication, allowing access to resource according to global access table and UACC. This is a very dangerous setting because it allows hackers to run jobs on the system. These jobs can then be used to exploit other vulnerabilities like leaky SVCs which do not require any DATASET resource. This setting is also a direct violation of the requirements for a C1 rating according to the Orange Book. The flag is available through the BATCHALLRACF field in the SYSTEM NEWLIST.

- User with CLAUTH can bypass generic profiles / not B1 compliant

The SETROPTS NOGENERICOWNER setting for this system permits people with class authorization to circumvent generic profiles they do not have access on. They can do this by creating a more specific resource profile and giving themselves access through that profile. The GENERICOWNER setting was introduced to counter that risk, but it is not in use. This setting is also a direct violation of the requirements for a B1 rating according to the Orange Book. The setting is available through the GENERICOWNER field in the SYSTEM NEWLIST.

- Attempts to change protection not audited

  The SETROPTS NOCMDVIOL setting for this system causes security violations on RACF commands to be omitted from the audit trail. Unsuccessful attempts can be a sign of unauthorized attempts to tamper with the system, so should be audited. The setting is available through the CMDVIOL field in the SYSTEM NEWLIST.

- Apparently unused userids increase risk of hacking

  The SETROPTS NOINACTIVE setting for this system assures that user IDs remain usable even though they have not been used for years. Because any secret, a password for example, has a chance of being leaked that increases with time, this is a very dangerous setting. This is a real risk because you cannot be certain that all of the old RACF databases and backups were run with the ERASEONSCRATCH option for both disk and tape. If you want to investigate further, use the zSecure **AU.S** option to create reports that summarize how long valid user IDs have been unused and how old valid passwords are. Common settings for the NOINACTIVE parameter are in the 30 to 90 days range. Less safe systems have set it to 255. This setting is available through the INACTIVE field in the SYSTEM NEWLIST.

- Password risk increases with age

  The SETROPTS PASSWORD(NOINTERVAL) setting for this system assures that passwords remain valid for indefinite length. Since any secret (like a password) has a chance of being leaked that increases with time, this is a very dangerous setting. If you think you do not run that risk ask yourself what you do with old RACF databases and backups of RACF databases, do you really use erase-on-scratch on disk as well as tape? The AU.S category RACF USER contains reports that summarize how old your passwords are that can still be used for authentication, in case you want to investigate further. The most common setting for this parameter is in the 30 day range. Less safe systems have set it to 90 days or even 255. The setting is available as field INTERVAL in SYSTEM NEWLIST.

- Without MINCHANGE users can thwart the PWDHISTORY more easily

  This audit concern reflects the SETROPTS PASSWORD(MINCHANGE(0)) setting. It indicates that users can change their passwords more than once on the same day. Consequently, the user can clear his password history easily.

- Userid stealing by hackers undetectable

  The SETROPTS NOINITSTATS setting for this system means that the last use date of userids is not being maintained. This means that the users do not get a message at logon stating the last logon date and hence cannot identify (mis)use of their userid by others. The setting is available as field INITSTATS in SYSTEM NEWLIST.

- OPERATIONS activity undetectable

  The SETROPTS NOOPERAUDIT setting for this system means that no audit trail is written for activities by users that get access through their OPERATIONS or group-OPERATIONS attribute. Hence misuse of these userids can certainly not be detected. Statistics show most fraud is perpetrated by insiders.

Logging activity provides a deterrent against misuse. The setting is available as field OPERAUDIT in SYSTEM NEWLIST.

- Warnings do not prevent unauthorized access / not C2 compliant

  The SETROPTS PROTECTALL(WARNING) setting for this system means that access to data sets is granted by default. This setting is counter to any *protection by default* policy you might have. Some people mistakenly believe that this settings means *prevent access and warn*, but it means *allow access and warn*. This setting is also a direct violation of the requirements for a C2 rating according to the Orange Book. The parameter setting is available through the PROTECTALL field in the SYSTEM NEWLIST.

- The security system is not even called for each dataset / not C2 compliant

  The SETROPTS NOPROTECTALL setting for this system means that access to data sets is allowed by default. This is counter to any *protection by default* policy you might have. This setting is also a direct violation of the requirements for a C2 rating according to the Orange Book. The parameter setting is available as field PROTECTALL in SYSTEM NEWLIST.

- Disk scavenging threat not countered / not C2 compliant

  The SETROPTS NOERASE or ERASE setting for this system means that residual data in disk data sets is not cleared when they are deleted because the RACF DATASET profile does not have the ERASE flag enabled. As a result, sensitive data is accessible by arbitrary users through reallocation of the disk space. Some sites claim to have taken other countermeasures, namely forcing the data set to be empty at allocation. However, these countermeasures are typically limited to writing a file mark on the first track of the data sets and resetting the last block pointer. Although this operation gives the impression that the data set is empty when read with ISPF BROWSE for example, it does not prevent a program from accessing the other tracks in the data set and reading residual data from there. This setting is also a direct violation of the requirements for a C2 rating according to the Orange Book which requires that all data sets have the ERASE attribute. You can run the SETROPTS ERASE(ALL) command to set the attribute, but only after taking some performance measures to prepare your system for the new setting. As a rule of thumb, you must double the number of volumes mounted PUBLIC to cope with the doubling of the I/O load for temporary data sets. Also for systems with shared DASD, hardware catalog/VVDS reserves might require conversion to system-wide enqueues to prevent long catalog lockouts during VSAM data set erasure. The parameter setting is available through the ERASEONSCRATCH field in the SYSTEM NEWLIST.

- Security/integrity flaw remediation no longer guaranteed

  The operating system/RACF release is no longer in service with IBM. Hence security or integrity exposures will no longer be fixed. You should upgrade to a more recent version of the operating system to get the benefits of flaw remediation. The end-of-service date supplied by IBM for your operating system release level is compared separately against the dates that the CKFREEZE or UNLOAD were made. If no CKFREEZE is used, or a live database is used instead of an UNLOAD, the check is done against the current date. For a database copy the check is skipped. The release levels checked are available as fields MVSLEVEL and RACFLEVEL in NEWLIST TYPE=SYSTEM.

- Administrator activity undetectable

  The SETROPTS SAUDIT setting for this system means that no audit trail is written for activities by users that get access through their SPECIAL or group-SPECIAL attribute. Hence misuse of these userids can certainly not be

detected. Statistics show most fraud is perpetrated by insiders. Logging activity provides a deterrent against misuse. The setting is also available as field SAUDIT in NEWLIST TYPE=SYSTEM.

- Tape volumes are unprotected / not C1 compliant

  The SETROPTS NOTAPEDSN NOCLASSACT(TAPEVOL) setting for this system means that data on tape is not protected properly. This typically allows access to sensitive data through backup tapes. Even if you have a tape management system with extra protection measures, this usually is not sufficient. This setting is a direct violation of the requirements for a C1 rating according to the Orange Book. The parameter settings are available as fields TAPEDSN and TAPEVOL in NEWLIST TYPE=SYSTEM and field ACTIVE in NEWLIST TYPE=CLASS for CLASS=TAPEVOL.

- Tape data sets are unprotected unless TAPEVOL profiles exist.

  The SETROPTS NOTAPEDSN CLASSACT(TAPEVOL) setting for this system means that data on tape is only protected if TAPEVOL profiles exist. You should check that all backup tapes (typically containing sensitive data) are protected by a TAPEVOL profile, even if they are in scratch status (unless you want to erase them at expiry). The simplest way to accomplish proper protection is to have a separate pool for your backup tapes with a naming convention and a generic TAPEVOL profile with UACC(NONE) and permits for DASD management tasks, for example, B*.

  The parameter settings are available as field TAPEDSN and TAPEVOL in NEWLIST TYPE=SYSTEM and field ACTIVE in NEWLIST TYPE=CLASS for CLASS=TAPEVOL.

- Hacker can read/write any tape dataset by adding and backspacing / not C1 compliant

  The SETROPTS TAPEDSN NOCLASSACT(TAPEVOL) setting for this system means that data on tape is not protected properly. It is a widely spread misconception that tapes might be protectable by data set name only. Because a user might always create a data set with his own userid as high-level qualifier, he can add a data set to a tape that is not yet full, and gain access to the tape volume. Tape cartridge units do not have the equivalent of DASD extent checking, the hacker can then use file space backward commands to obtain access to the other data sets on tape. This attack can be countered by the SINGLEDSN or equivalent option in tape management systems, but usually we find this is not being used for backup tapes. The simplest way to accomplish proper protection is to have a separate pool for your backup tapes with a naming convention and a generic TAPEVOL profile with UACC(NONE) and permits for DASD management tasks, for example, B*. This setting is a direct violation of the requirements for a C1 rating according to the Orange Book.

  The parameter settings are available as field TAPEDSN and TAPEVOL in NEWLIST TYPE=SYSTEM and field ACTIVE in NEWLIST TYPE=CLASS for CLASS=TAPEVOL.

- Users can use same passwords over and over

  The SETROPTS PASSWORD(NOHISTORY) setting for this system allows users to keep the same password even though a password interval has been set. Since any secret (like a password) has a chance of being leaked that increases with time, this is a very dangerous setting. If you think you do not run that risk ask yourself what you do with old RACF databases and backups of RACF databases, do you really use erase-on-scratch on disk as well as tape? The setting is also available as field (PWD)HISTORY in NEWLIST TYPE=SYSTEM.

- Too many password violations allowed

  The SETROPTS PASSWORD(NOREVOKE) or PASSWORD(REVOKE(11)) or worse setting for this system allows hackers to do at least 10 password attempts per legitimate user logon (e.g. once a day) without a great chance of anybody noticing. This might well be sufficient to break into a system if the hacker knows the password rules. Common practice is to set REVOKE in the range 3 to 5, allow initial typing mistakes but preventing systematic guessing over a number of days. The setting is also available as field (PWD)REVOKE in NEWLIST TYPE=SYSTEM.
- SECLABEL integrity not guaranteed / not B1 compliant

  The SETROPTS NOSECLABELCONTROL setting for this system means that anybody with READ access to the security label might change profiles classified under that security label. Hence integrity of the label is not guaranteed. This setting is also a direct violation of the requirements for a B1 rating according to the Orange Book. The parameter setting is available as field SECLABELCONTROL in NEWLIST TYPE=SYSTEM.
- SECLABELs not required / not B1 compliant

  The SETROPTS NOMLACTIVE or MLACTIVE(WARNING) setting for this system allows access to data without security labels being required. This means that there is no Mandatory Access Control active. This setting is a direct violation of the requirements for a B1 rating according to the Orange Book. The parameter setting is available as field MLACTIVE in NEWLIST TYPE=SYSTEM.
- Users can declassify data / not B1 compliant

  The SETROPTS NOMLS or MLS(WARNING) setting for this system allows users to declassify data. This means that there is no Mandatory Access Control enforced. This setting is a direct violation of the requirements for a B1 rating according to the Orange Book. The parameter setting is available as field MLS in NEWLIST TYPE=SYSTEM.
- SECLABEL meaning not stabilized / not B1 compliant

  The SETROPTS NOMLSTABLE setting for this system means that the meaning of a security label in terms of security categories and security level might be changed. This means that there is no Mandatory Access Control enforced. This setting is a direct violation of the requirements for a B1 rating according to the Orange Book. The parameter setting is available as field MLSTABLE in NEWLIST TYPE=SYSTEM.
- Uncataloged dataset not B1 audited / not B1 compliant

  The SETROPTS NOCATDSNS or SETROPTS CATDSNS(WARNING) setting for this system means that uncataloged data sets, including temporary data sets, are accessible to normal users without the proper audit trails being written. This setting is a direct violation of the requirements for a B1 rating according to the Orange Book. The parameter setting is available as field CATDSNS in NEWLIST TYPE=SYSTEM.

The following audit concerns have been defined regarding RACF concerns in the DMS area:

- DMS ignores RACF

  The RACFPROCN setting for this system means that DMS does not consult RACF when processing RACF indicated data sets. This allows access to other people's data through DMS. The parameter setting is available as field DMSRACFPROC in NEWLIST TYPE=SYSTEM.
- DMS will not backup RACF protected data

The RACFSUPPN setting for this system means that DMS does backup or restore any RACF-indicated data sets. This might be a serious risk for availability. The parameter setting is available as field DMSRACFSUPP in NEWLIST TYPE=SYSTEM.

- DMS ignores RACF for non-indicated data

  The RACFALWZN setting for this system means that DMS does not consult RACF when processing non-RACF-indicated data sets (usually the majority of data sets). This allows access to other people's data through DMS. The parameter setting is available as field DMSRACFALWZ in NEWLIST TYPE=SYSTEM.

- DMS restore to newname does not check RACF authority

  The RACFNEWNY setting for this system means that DMS does not consult RACF with the old name when renaming data sets during a restore. This allows access to other people's data though DMS by restoring their data set with a new name that you do have access to. This dangerous parameter setting has been found many times during security reviews. The parameter setting is available as field DMSRACFNEWN in NEWLIST TYPE=SYSTEM.

- DMS parameter override not secured

  The absence of the SECURE_PARMLIB flag in the load module ADSTS148 for this system means that DMS does not prevent a user from calling DMS with an alternate parameter library, opening up all other holes documented here for the DMS area. This allows access to other people's data. This dangerous parameter setting has been found many times during security reviews. The parameter setting is available as field DMS_SECURE_PARMLIB in NEWLIST TYPE=SYSTEM.

- DMS does not use DASDVOL, this is inefficient

  The SECURVOLN setting for this system means that DMS does not check the DASDVOL class first. While this is normal for systems with mandatory Access Control (B1), it is much more efficient for daily backups in RACF systems that are to run C2 or lower. The parameter setting is available as field DMSSECURVOL in NEWLIST TYPE=SYSTEM.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 321. AUDIT NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

This fields returns the complex name for the system where the audit concern was detected. The default output length is 8 characters.

PARMNAME

Name of the NEWLIST TYPE=SYSTEM CARLa field that contains the setting/parameter that caused the audit concern. The field AREAPARM contains the name of the system setting/parameter as found e.g. in the PARMLIB or on the SETROPTS command.

This field can be empty when the audit concern does not (directly) apply to a NEWLIST TYPE=SYSTEM field. The PARMNAME field can be used for generating NEWLIST TYPE=SYSTEM queries.

PARMVALUE

Value of the parameter listed in field PARMNAME that caused this audit concern. This is always a character value, even if in NEWLIST TYPE=SYSTEM the parameter is not a character value. The default output length is 8 characters.

SYSTEM

The name of the system where the audit concern was detected (SMF id for MVS systems). The default output length is 8.

AUTAB: RACF Authorized Caller Table

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•		

The AUTAB NEWLIST (NEWLIST TYPE=AUTAB) displays the Authorized Caller Table. This NEWLIST generates one entry for each entry in the table. A unique key is SYSTEM ORDER. Unless otherwise stated, all fields can be used for SELECT or EXCLUDE processing as well as in the output commands (LIST, SORTLIST, DISPLAY and SUMMARY).

Field descriptions

You can use the following fields to select and create audit reports for the RACF Authorized Caller Table.

ATTR, AUTH

A string containing the program's authorization. If the RACLIST flag is set (RACLIST=YES), this string contains 'RACLIST'; if the RACINIT flag is set (RACINIT=YES), this string contains 'RACINIT'; if both are set, it contains 'RACLIST RACINIT'.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. The complex name can come from the ALLOC COMPLEX parameter or default to a system name.

ORDER, ORG

The original order (entry number) of this program in the authorized caller table. The first entry in the table has ORDER=1.

PROGRAM

The name of the program. This program must reside in an APF-authorized library.

RACINIT

RACINIT flag. A program that has this flag set (RACINIT=YES) is authorized to issue RACINIT requests, which perform user and potentially password verification.

RACLIST

RACLIST flag. A program that has this flag set (RACLIST=YES) is authorized to issue RACLIST requests, which load profiles into the main in-storage.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. The field length is 8 characters to cater to VM systems.

CICS_PROGRAM: CICS programs

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
				•	•	•

This section documents the fields for the NEWLIST TYPE=CICS_PROGRAM. This NEWLIST type lists one entry per active CICS program for a CICS region in each system. An entry is uniquely identified by the following fields: SYSTEM, COMPLEX, ASID, JOBNAME, and PROGRAM.

Field descriptions

The `CICS_PROGRAM NEWLIST` provides the following fields for reporting.

API_SUBSET

This field specifies whether the CICS program is restricted to a data program link (DPL) subset of the CICS API commands. Field value: Yes or No. If the value is Yes, the program cannot issue the following commands:

- Terminal control commands that reference the principal facility.
- Options of ASSIGN that return terminal attributes.
- BMS commands.
- Signon and signoff commands.
- Batch data interchange commands.
- Commands that address the TCTUA.

ASID

This field contains the address space ID associated with the CICS region. The address space ID is a 2-byte hexadecimal number; the JOBNAME field shows the related job.

AUDITCONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field as a programming interface. The AUDITCONCERN field can contain one or more concerns separated by commas.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 322. CICS_PROGRAM NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

CEDF

This field specifies the action taken by the execution diagnostic facility (EDF) when the CICS program is running under EDF control. If the value is Yes, the EDF diagnostic screens are displayed. Field value: Yes or No.

CLASS

This field specifies the resource class used to secure the CICS program, for example, the MCICSPPT resource class. Maximum length: 8 characters.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

DATA_KEY

This field specifies whether the storage that CICS allocates at task initialization is obtained from CICS-key or user-key storage. If the value is Yes, storage is obtained from user-key storage. If the value is No, storage is obtained from CICS-key storage. Field value: Yes or No.

DATA_LOCATION

This field specifies whether the data returned by commands using the SET option can be located above the 16 MB line. If the value is No, the data returned is located below the 16 MB line. Field value: Yes or No.

ENABLED

This field specifies the program status. If the value is Yes, the program can be executed normally. If the value is No, the program is disabled and cannot be executed. Field value: Yes or No.

JOBID

This field contains the JES job ID of the CICS region. Maximum length: 8 characters.

JOBNAME

This field contains the JES job name of the CICS region. Maximum length: 8 characters.

JVM

This field specifies whether the program is a Java program that has to run in a Java Virtual Machine (JVM) in a CICS region. Field value: Yes or No.

JVMCLASS

This field specifies the fully-qualified name of the main class in a Java program. The fully-qualified name *package_name.class_name* is the class name qualified by the package name. For example, HelloWorld.HelloCICSWorld. Maximum length: 255 characters.

JVMPROF

This field specifies the name of a JVM profile, a file in the z/OS UNIX directory that is specified by the JVMPROFILEDIR system initialization parameter. Maximum length: 8 characters.

LANG_DED

This field specifies the program language that was deduced by CICS for the program.

LANG_DEF

This field specifies the programming language defined on the resource definition.

OPENAPI_DED

This field specifies if the program is restricted (Yes) to the CICS API or not (No). This value is deduced by CICS for the program. Field value: Yes or No.

OPENAPI_DEF

This field specifies if the program is restricted (Yes) to the CICS API or not (No). This value is the API attribute of the installed program definition.

PGM_TYPE

This field shows the CICS program type. Field values: PROGRAM, MAPSET, and PARTITIONSET.

PROGRAM

This field specifies the name of the CICS program. Maximum length: 8 characters.

QUALIFIED_RESOURCE

This field specifies the qualified resource name. The name is the concatenation of the RESOURCE_LOCATION and the RESOURCE separated by a colon, for example: IPO1.CICS.CICSTS41.PGM:CICSSTC.DFHEMTP. Maximum length: 48 characters.

RACF_ACL

This repeated field can be used to display the access and conditional access lists of a profile. It can only be used for output on the SORTLIST, DISPLAY, and (D)SUMMARY commands. The display contains userid, access, ACL id, conditional class, and the conditional profile name. The default output length is 45 characters, but the profile name can be 255 characters so the maximum output length is 290 characters.

Use the EXPLODE output modifier for a complete access list that includes access per user through each connect group. Use the RESOLVE output modifier for a resolved access list showing the highest access of each user or group. Use the EFFECTIVE output modifier to extend the resolved access list into the effective one, which also includes access due to operations or group operations. Be aware that connect information is needed for RESOLVE, EFFECTIVE and EXPLODE. You can use the UNIVERSAL modifier to force collection of all relevant data. The SCOPE modifier can be used to extend the modifiers EXPLODE, RESOLVE, and EFFECTIVE with administrative access. To print the ids, the access levels, or both, the ACLACCESS, ACLID and ACLIDACCESS formats can be used. See "Format names for input and output" on page 810.

RACF_CLASS

This field contains the resource class of the profile that protects the resource. The resource class can be a member class or a grouping class. The RACF_PROFILE and RACF_CLASS fields are part of the repeat group of RACF information. Maximum length: 8 characters.

RACF_PROFILE

This field contains the name of the profile that protects the resource. The profile can be a member class profile or a grouping class profile. The RACF_PROFILE and RACF_CLASS fields are part of the repeat group of RACF information. Maximum length: 8 characters.

RACF_UACC

This field contains the effective universal access authority (UACC) to the program. The UACC is determined from all grouping and non-grouping resource profiles that describe the program. Field values: NONE, READ, EXECUTE, UPDATE, CONTROL, or ALTER.

RELOAD

This field specifies whether a program control LINK, LOAD, or XCTL request reloads a new copy of a previously loaded program. If the value is No, any valid copy of the program currently in storage is reused for the request. If the value is Yes, a new copy of the program is loaded into storage for every program control request. This attribute does not apply to Java programs. Field value: Yes or No.

RESIDENT

This field specifies the resident status of the program. This attribute does not apply to JVM programs. If the value is Yes, the program is loaded on first reference and is permanently resident in virtual storage, but is to be pageable by the operating system. Field value: Yes or No.

RESOURCE

This field specifies the name of the resource that is used to secure the CICS program. Maximum length: 246 characters. Default length: 17 characters.

RESOURCE_LOCATION

This field indicates the environment where the resource is relevant. This field is the concatenation of several fixed strings, fields, and lookups, such as *system*.CICS.*jobname*.PGM. An example value of this format is IPO1.CICS.CICSTS41.PGM. Maximum length: 30 characters.

RMT_DYNAMIC

This field specifies whether the request to execute the CICS program can be dynamically routed. If the value is Yes, the CICS dynamic routing program is invoked. Field value: Yes or No.

RMT_NAME

This field specifies the name by which the CICS program is known in the remote CICS region, specified by the RMT_SYSTEM field. Maximum length: 8 characters.

RMT_SYSTEM

The field specifies the name of a remote CICS region to which a CICS client region ships a program link (DPL) request. Maximum length: 8 characters.

RMT_TRANSID

This field specifies the name of the transaction that the remote CICS server program attaches to and under which it runs the remote application program. Maximum length: 8 characters.

STEPNAME

This field contains the step name associated with the CICS region. Maximum length: 8 characters.

SYSIDNT

This field specifies a 1-to 4-character name to identify your local CICS region.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. The field length is 8 characters for compatibility with other NEWLIST types. Maximum length: 8 characters.

THREADSAFE_DED

This field shows the threadsafe standard setting that is deduced by CICS for the program. If the value is Yes, the program is written to threadsafe standards. Field value: Yes or No.

THREADSAFE_DEF

This field indicates the threadsafe standard setting defined for the CICS program. If the value is Yes, the program is written to threadsafe standards. Field value: Yes or No.

VTAM_APPLID

This field specifies the specific VTAM application identifier (APPLID) for the CICS region. Maximum length: 8 characters.

CICS_REGION: CICS regions

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•		•	•	•	•	•

This section documents the fields for the NEWLIST TYPE=CICS_REGION. This NEWLIST type lists one entry per active CICS region for each system. An entry is uniquely identified by the following fields: SYSTEM, COMPLEX, ASID, and JOBNAME.

Field descriptions

The CICS_REGION NEWLIST provides the following fields for reporting.

AI_CONSOLE

This field identifies whether autoinstall status for consoles is active. Field value: Yes or No.

AI_EXIT

This field contains the name of the autoinstall exit control program for console autoinstall. Maximum length: 8 characters.

ASID

This field contains the address space ID associated with the CICS region. The address space ID is a 2-byte hexadecimal number; the JOBNAME field shows the related job.

AUDITCONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field as a programming interface. The AUDITCONCERN field can contain one or more concerns separated by commas.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 323. CICS_REGION NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

CICS_LEVEL

This field identifies the CICS system release level of the active CICS region.

CLASS_APPC

This field specifies the resource class used to perform APPC session security. This resource class is used to determine access permission when SEC_APPC=YES. The field is empty when SEC_APPC=NO. Maximum length: 8 characters.

CLASS_CMD

This field specifies the resource class used to secure CICS commands. This resource class is used to determine access permission when SEC_CMD=YES and

command checking is active for the transaction. The field is empty when SEC_CMD=NO. Maximum length: 8 characters.

CLASS_DB2

This field specifies the CICS resource class used to secure the DB2ENTRY resources. This class is used to determine access permission when SEC_DB2=YES. The field is empty when SEC_DB2=NO. Maximum length: 8 characters.

CLASS_DCT

This field specifies the resource class used to secure the CICS transient data. This resource class is used to determine access permission when SEC_DCT=YES and resource checking is active for the transaction. The field is empty when SEC_DCT=NO. Maximum length: 8 characters.

CLASS_EJB

This field specifies the CICS resource class used to secure the EJBROLE resources. This resource class is used to determine access permission when SEC_EJB=YES. The field is empty when SEC_EJB=NO. Maximum length: 8 characters.

CLASS_FCT

This field specifies the CICS resource class used to secure the CICS files. This resource class is used to determine access permission when SEC_FCT=YES and resource checking is active for the transaction. The field is empty when SEC_FCT=NO. Maximum length: 8 characters.

CLASS_JCT

This field specifies the CICS resource class used to secure the CICS journals. This resource class is used to determine access permission when SEC_JCT=YES and resource checking is active for the transaction. The field is empty when SEC_JCT=NO. Maximum length: 8 characters.

CLASS_PCT

This field specifies the CICS resource class used to secure the CICS-started transactions. This resource class is used to determine access permission when SEC_PCT=YES. The field is empty when SEC_PCT=NO. Maximum length: 8 characters.

CLASS_PPT

This field specifies the CICS resource class used to secure the CICS programs. This resource class is used to determine access permission when SEC_PCT=YES and resource checking is active for the transaction. The field is missing when SEC_PCT=NO. Maximum length: 8 characters.

CLASS_PSB

This field specifies the CICS resource class used to secure PSB schedule requests in the CICS region. This resource class is used to determine access permission when SEC_PSB=YES and resource checking is active for the transaction. The field is empty when SEC_PSB=NO. Maximum length: 8 characters.

CLASS_RES

This field specifies the CICS resource class used to secure the general CICS resources. This resource class is used to determine access permission when SEC_RES=YES and resource checking is active for the transaction. The field is empty when SEC_RES=NO. Maximum length: 8 characters.

CLASS_SUR

This field specifies the CICS resource class used to determine if a CICS region user ID has authorization to act as a surrogate user. This resource class is used when SEC_SUR=YES. The field is empty when SEC_SUR=NO. Maximum length: 8 characters.

CLASS_TRN

This field specifies the CICS resource class used to secure the attached transactions. This resource class is used to determine access when SEC_TRN=YES. The field is empty when SEC_TRN=NO. Maximum length: 8 characters.

CLASS_TST

This field specifies the CICS resource class used to secure the CICS temporary storage queues. This resource class is used to determine access when the following conditions exist: SEC_TST=YES, resource checking is active for the transaction, and the temporary storage queue has been defined with TYPE=SECURITY. This field is empty when SEC_TST=NO. Maximum length: 8 characters.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

CSD_DISP

This field contains the disposition of the CICS system definition (CSD) data set. A value of OLD means that the data set is used exclusively by the CICS region. A value of SHR means that the data set can be shared with other users or jobs.

CSD_DSN

This field contains the name of the CICS system definition (CSD) data set. The CSD file is a VSAM data set that contains a resource definition record for every resource defined to CICS by means of the CEDA transaction or the DFHCSDUP utility program.

CSD_READONLY

This field determines whether the CICS system definition (CSD) data set in use by the CICS region is set for read-only access. A value of Yes means that the data set cannot be updated by using the CEDA and CEDB transactions.

DEFAULT_USER

This field contains the default user id associated with the CICS region.

DLI_PSBCHK

This field determines whether a security check for remote users is performed at PSB schedule time. Field value: Yes or No.

EJBROLE_PREFIX

This field specifies the prefix that is used to qualify the security role defined in the deployment descriptor of an enterprise bean. Maximum length: 16 characters. The prefix is applied to the security role when:

- a role is defined to an external security manager
- CICS maps a security role to a RACF user ID
- an application invokes the `isCallerInRole()` method

GMTEXT

This field contains the default text that is displayed by the good morning or CSGM transaction. Maximum length: 246 characters.

GMTRAN

This field contains the CICS transaction that is invoked when a user logs on to the CICS region. If the field value is CSGM, the text in the GMTEXT field is displayed. Maximum length: 4 characters.

GNTRAN

This field specifies the good night transaction that CICS invokes upon expiration of a user's terminal timeout period. If set to the default value of GNTRAN=NO, CICS attempts to sign off the terminal user instead of invoking the good night transaction. The success of the signoff attempt depends on the value of the SIGNOFF attribute of the terminal's TYPETERM definition. Maximum length: 4 characters.

GRPLIST

This field is a repeat group which specifies the resource groups that contain the resource definitions required by the CICS region and that are installed as a part of CICS initialization. Resource groups can be either specific or generic. A maximum of four resource groups can be specified. Maximum length: 8 characters.

HPO

This field reports whether the MVS high-performance option (HPO) is active. If HPO=Yes, HPO is used improve user performance by reducing the transaction pathlength for processing VTAM requests. Field value: Yes or No.

HPO_SVCNO

This field specifies the Type 6 SVC number that is used by CICS to improve performance by reducing the transaction pathlength through VTAM.

JOBID

This field might contain the JES job ID of the CICS region. Maximum length: 8 characters.

JOBNAME

This field might contain the JES job name of the CICS region. Maximum length: 8 characters.

KEYRING

This field specifies the fully-qualified, case-sensitive name of the key ring file that is stored in an external security manager database. The key ring contains the keys and X.509 certificates that are used by CICS to support secure sockets layer (SSL) and Web services security. Maximum length: 47 characters.

PGM_LLACOPY

This field specifies whether CICS issues an LLACOPY macro each time a module is located from the RPL data set. Field values: Yes, No, or New.

PGM_LLACOPY=Yes
CICS issues the LLACOPY macro either on the first ACQUIRE or on any subsequent NEWCOPY or PHASEIN requests. This ensures that CICS always obtains the latest copy of any LLA-managed modules.

PGM_LLACOPY=No
CICS never issues an LLACOPY macro. Instead, each time the RPL data set is searched for a module, a BLDL macro is issued.

PGM_LLACOPY=New
CICS issues the LLACOPY macro when loading a module as a result of a NEWCOPY or PHASEIN request. A BLDL macro is issued for all other requests.

PGM_LPA

This field specifies whether load modules are loaded from the link pack area (LPA). Field value: Yes or No.

PGM_PRVMOD

This field is a repeated field that lists the modules that the CICS region cannot use from the MVS link pack area (LPA). Each repeated entry has a length of 8 characters. Maximum length: 8 characters.

PGM_RENTPGM

This field specifies whether CICS uses read-only, key-0 protected storage for re-entrant programs (PGM_RENTPGM=Yes). For CICS production regions, a setting of PGM_RENTPGM=Yes is commonly used, and for CICS development regions, a setting of PGM_RENTPGM=No is commonly used. Field value: Yes or No.

PLTPI_SEC

This field specifies whether CICS performs command security or resource security checking for PLT programs during CICS initialization. PLT programs run under the authority of the userid specified on PLTPI_USER, this userid must be authorized to access resources defined by the CICS PLTPISEC parameter. Field values: None, Cmdsec, Ressec, or All.

PLTPI_USER

This field specifies the userid that CICS uses for security checking for PLT programs that run during CICS initialization. All PLT programs run under the authority of this userid so it must be authorized to all the resources referenced by PLT programs, as defined by the CICS PLTPISEC parameter.

REGION_USER

This field specifies the userid that is associated with the CICS region. It is the default userid for the SEC_PREFIX if resource prefixing is requested, but no specific userid was specified, and it is also the userid that must be authorized to access CICS category 1 transactions. Maximum length: 8 characters.

SEC_APPC

This field shows whether the SESSION segment for the profiles in the APPCLU class are used during the verification of APPC BIND security when binding APPC sessions. Field value: Yes or No.

SEC_CMD

This field specifies whether command security checking is performed for the CICS region. A transaction definition controls whether command security checking is performed for an individual transaction. Field value: Yes or No.

SEC_CMDSEC

This field specifies whether command security checking is always performed for the CICS region independent of security checking required by transaction definitions. Field value: Yes or No.

SEC_DB2

This field specifies whether DB2 resource security checking is performed for the CICS region. If the value is Yes, the general resource class specified in CLASS_DB2 is used to check whether the userid associated with the CICS DB2 transaction has access to the DB2ENTRY referenced by the transaction. Field value: Yes or No.

SEC_DCT

This field specifies whether transient data resource security checking is performed for the CICS region. If the value is Yes, the general resource class specified in CLASS_DCT is used to check whether the userid associated with the CICS transaction has access to the specified transient data. Field value: Yes or No.

SEC_EJB

This field specifies whether CICS support for security roles is enabled. If the value is Yes:

- When an application invokes a method of an enterprise bean, CICS calls the external security manager to verify that the userid associated with the transaction is defined in at least one of the security roles associated with the method.
- When an application invokes the isCallerInRole() method, CICS calls the external security manager to determine whether the userid associated with the transaction is defined in the role specified on the method call.

Field value: Yes or No

SEC_ESM

This field specifies whether CICS resource security checking is performed for the CICS region by an external security manager, for example, RACF. Field value: Yes or No.

SEC_FCT

This field specifies whether file resource security checking is performed for the CICS region. If the value is Yes, the general resource class specified in CLASS_FCT is used to check whether the userid associated with the CICS transaction has access to the specified file. Field value: Yes or No.

SEC_JCT

This field specifies whether journal resource security checking is performed for the CICS region. If the value is Yes, the general resource class specified in CLASS_JCT is used to check whether the userid associated with the CICS transaction has access to the specified journal. Field value: Yes or No.

SEC_PCT

This field specifies whether resource security checking for started transactions is performed for the CICS region. If the value is Yes, the general resource class specified in CLASS_PCT is used to check whether the userid associated with the CICS transaction has access to the specified transaction. Field value: Yes or No.

SEC_PPT

This field specifies whether resource security checking of application programs is performed for the CICS region. If the value is Yes, the general resource class specified in CLASS_PPT is used to check whether the userid associated with the CICS transaction is authorized to use LINK, LOAD, or XCTL commands to invoke other programs. Field value: Yes or No.

SEC_PREFIX

This field specifies the string used to prefix all SAF resource names. It is alphanumeric and must start with an alphabetic character. This field is empty if prefixing is not used for this CICS region. Maximum length: 8 characters.

SEC_PSB

This field specifies whether program specification block (PSB) resource security checking is performed for the CICS region. If the value is Yes, the general resource class specified in CLASS_PSB is used to check whether the userid associated with the CICS transaction is authorized to access the IMS PSB. Field value: Yes or No.

SEC_RES

This field specifies whether resource security checking is performed for the CICS region. A transaction definition controls whether command security checking is performed for an individual transaction. Field value: Yes or No.

SEC_RESSEC

This field specifies whether resource security checking is always performed for the CICS region independent of security checking required by individual transaction definitions. Field value: Yes or No.

SEC_SUR

This field specifies whether surrogate user resource security checking is performed for the CICS region. If the value is Yes, the general resource class specified in CLASS_SUR is used to check whether the CICS region userid has authorization to act as a surrogate. Field value: Yes or No.

SEC_TRN

This field specifies whether security checking is done to determine a user's authority to execute a transaction. If the value is Yes, the resource class specified in CLASS_TRN is used to check whether the userid associated with the CICS transaction has access to the transaction. Field value: Yes or No.

SEC_TST

This field specifies whether temporary storage resource security checking is performed for the CICS region. If the value is Yes, the general resource class

specified in CLASS_TST might be used to check whether the userid associated with the CICS transaction has access to the specified temporary storage queue. Field value: Yes or No.

SEC_UNIXFILE

This field specifies whether UNIX file security checking is performed for the CICS region. If the value is Yes, then z/OS UNIX system services controls access to the z/OS UNIX files and access is not managed directly by RACF. Field value: Yes or No.

SSL_ENCRYPT

This field specifies whether Secure Sockets Layer (SSL) is used for encrypting transmitted data. Field value: Yes or No.

STEPNAME

This field contains the step name associated with the CICS region. Maximum length: 8 characters.

STOR_CMDPROT

This field specifies whether CICS validates the start addresses of storage that is referenced as output parameters on EXEC CICS commands. If the value is Yes, CICS validates the start address to ensure that the application program has write access. If an application program asks CICS to write to an area where it does not have addressability, CICS abends the task with an AEYD abend. Field value: Yes or No.

STOR_CWAKEY

This field specifies whether CICS obtains storage for the common work area (CWA) in the CICS-key storage. If the value is Yes, storage is obtained in the CICS-key storage, otherwise it is obtained from the user-key storage. Field value: Yes or No.

STOR_PROT

This field specifies whether storage protection is used in the CICS region. If the value is Yes, CICS operates with storage protection and observes the storage keys and execution keys used in various system and resource definitions. Field value: Yes or No.

STOR_TASKCHK

This field specifies whether the task storage-violation checking at startup is activated or deactivated. Field value: Yes or No.

STOR_TCTUAKEY

This field specifies whether CICS obtains storage for the terminal user areas (TCTUA) in the CICS key storage. If the value is Yes, then storage is obtained in the CICS-key storage otherwise it is obtained from the user-key storage. Field value: Yes or No.

STOR_TCTUALOC

This field specifies where terminal user areas (TCTUA) are to be stored. If the value is Yes, the TCTUA is stored in virtual storage above the 16 MB line. Field value: Yes or No.

STOR_TERMCHK

This field specifies whether the terminal storage-violation checking is activated or deactivated. If the value is Yes, TIOA storage violations are checked. Field value: Yes or No.

STOR_TRANISO

This field and the STOR_PROT parameter specify whether transaction isolation is active in the CICS region. If STOR_TRANISO=Yes and STOR_PROT=Yes, CICS operates with transaction isolation. Transaction isolation ensures that only user-key programs of transactions defined with ISOLATE(YES) have access to the user-key task-lifetime storage of their own task. Field value: Yes or No.

SVCNO

This field specifies the Type 3 SVC number that is used by the CICS region.

SYSIDNT

This field specifies a 1-to 4-character name to identify your local CICS region.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. The field length is 8 characters for compatibility with other NEWLIST types. Maximum length: 8 characters.

TRACE_CONFDATA

This field specifies whether CICS shows all user data that might otherwise appear only in CICS trace entries or in dumps that contain the VTAM receive any input area (RAIA). Field value: Yes or No.

TRACE_CONFTXT

This field specifies whether CICS allows VTAM to trace user data. Field value: Yes or No.

VTAM_APPLID

This field specifies the specific VTAM application identifier (APPLID) for the CICS region. Maximum length: 8 characters.

VTAM_GENAPPLID

This field specifies the generic VTAM application identifier (APPLID) for the CICS region. Maximum length: 8 characters.

VTAM_GRNAME

This field specifies the VTAM generic resource name used by a group of terminal-owning regions in a CICSplex to register to VTAM. Maximum length: 8 characters.

CICS_TRANSACTION: CICS transactions

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
				•	•	•

This section documents the fields for the NEWLIST TYPE=CICS_TRANSACTION. This NEWLIST type lists one entry per active CICS transaction for a CICS region in each system. An entry is uniquely identified by the following fields: SYSTEM, COMPLEX, ASID, JOBNAME. and TRANSACTION.

Field descriptions

The CICS_TRANSACTION NEWLIST provides the following fields for reporting.

ASID

This field contains the address space ID associated with the CICS region. The address space ID is a 2-byte hexadecimal number; the JOBNAME field shows the related job.

AUDITCONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field as a programming interface. The AUDITCONCERN field can contain one or more concerns separated by commas.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 324. CICS_TRANSACTION NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

CLASS

This field specifies the resource class used to secure the CICS program, for example, TCICSTRN. Maximum length: 8 characters.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

DATA_CLEAR

This field specifies whether task-lifetime storage for the transaction is to be cleared on transaction release. Releasing the storage prevents other tasks from accidently viewing data stored by this transaction in task-lifetime storage. Field value: Yes or No.

DATA_FREEZE

This field specifies whether the storage for the transaction is retained for the duration of the transaction. Field value: Yes or No.

DATA_KEY

This field specifies whether the storage that CICS allocates at task initialization is obtained from CICS-key or user-key storage. If the value is Yes, storage is obtained from user-key storage. If the value is No, storage is obtained from CICS-key storage. Field value: Yes or No.

DATA_LOCATION

This field specifies whether task life-time storage acquired by CICS for the transaction duration can be located above the 16 MB line in virtual storage. If the value is No, CICS acquires data storage located below the 16 MB line. Field value: Yes or No.

ENABLED

This field specifies the transaction status. If the value is Yes, the transaction is enabled and can be executed normally. If the value is No, the transaction is disabled and cannot be executed. Field value: Yes or No.

JOBID

This field contains the JES job ID of the CICS region. Maximum length: 8 characters.

JOBNAME

This field contains the JES job name of the CICS region. Maximum length: 8 characters.

OTS_TIMEOUT

This field specifies the a time (in hours, minutes, and seconds) that an enterprise bean Object Transaction Service (OTS) transaction, executing as a task under a CICS transaction, is allowed to execute before the initiator of the OTS transaction takes a syncpoint or rolls back the transaction. If the time period expires, CICS purges the task.

PRIORITY

This field specifies the transaction priority as a 1- to 3-digit decimal value from 0 to 255. This value is used to establish the overall transaction processing priority.

PROGRAM

This field specifies the name of the program to which CICS gives control in order to process this transaction. Maximum length: 8 characters.

QUALIFIED_RESOURCE

This field specifies the qualified resource name. The name is the concatenation of the RESOURCE_LOCATION and the RESOURCE separated by a colon, for example: IPO1.CICS.CICSTS41.TRN:CICSSTC.CEMT. Maximum length: 44 characters.

QUEUE_LOCAL

This field specifies whether local queuing on the local system is to be performed. Field value: Yes or No.

RACF_ACL

This repeated field can be used to display the access and conditional access lists of a profile. It can only be used for output on the SORTLIST, DISPLAY, and (D)SUMMARY commands. The display contains userid, access, ACL id, conditional class, and the conditional profile name. The default output length is 45 characters, but the profile name can be 255 characters so the maximum output length is 290 characters.

Use the EXPLODE output modifier for a complete access list that includes access per user through each connect group. Use the RESOLVE output modifier for a resolved access list showing the highest access of each user or group. Use the EFFECTIVE output modifier to extend the resolved access list into the effective one, which also includes access due to operations or group operations. Be aware that connect information is needed for RESOLVE, EFFECTIVE and EXPLODE. You can use the UNIVERSAL modifier to force collection of all relevant data. The SCOPE modifier can be used to extend the modifiers EXPLODE, RESOLVE, and EFFECTIVE with administrative access. To print the ids, the access levels, or both, the ACLACCESS, ACLID and ACLIDACCESS formats can be used. See "Format names for input and output" on page 810.

RACF_CLASS

This field contains the resource class of the profile that protects the resource. The resource class can be a member class or a grouping class. The RACF_PROFILE and RACF_CLASS fields are part of the repeat group of RACF information. Maximum length: 8 characters.

RACF_PROFILE

This field contains the name of the profile that protects the resource. The profile can be a member class profile or a grouping class profile. The RACF_PROFILE and RACF_CLASS fields are part of the repeat group of RACF information. Maximum length: 13 characters.

RACF_UACC

This field contains the effective universal access authority (UACC) to the program. The UACC is determined from all grouping and non-grouping resource profiles that describe the program. Field values: NONE, READ, EXECUTE, UPDATE, CONTROL, or ALTER.

RCVY_ACTION

This field specifies the action to be taken during two-phase commit processing when a CICS region fails, or loses connectivity with its coordinator, after the unit of work (UOW) has entered the in-doubt period. If the value is Yes, all changes made to recoverable resources are backed out, and the resources are returned to the state prior to the start of the UOW. If the value is No, all changes made to recoverable resources are committed, and the UOW is marked as completed. Field value: Yes or No.

RCVY_DTIME

This field specifies the amount of time (mmss) that CICS waits before it determines a deadlock time-out has occurred and purges the task.

RCVY_DUMP

This field specifies whether a call is made to the dump domain to produce a transaction dump if the transaction terminates abnormally. Field value: Yes or No.

RCVY_RESTART

This field specifies whether a transaction restart facility is used to restart tasks that terminated abnormally and were subsequently backed out by the dynamic transaction backout facility. Field values: Yes or No.

RCVY_RUNAWAY

This field specifies the maximum amount of time (in milliseconds) that a task running under this transaction can have control of the processor before it is assumed to be in a runaway condition (logical loop). When this interval expires, CICS can abnormally terminate the task.

- **0** - There is no limit and no runaway task detection is required for the transaction
- **milliseconds** - The runaway time limit is 500 to 2700000 milliseconds.

RCVY_RUNAWAY_SYSTEM

This field specifies ICVR system initialization parameter value and contains the amount of time, in milliseconds, that any task running under this transaction can have control of the processor before it is assumed to be in a runaway condition (logical loop). When the interval expires, CICS can abnormally terminate the task.

RCVY_SPURGE

This field specifies whether the transaction is initially "system purgeable" or not. Field value: Yes or No.

RCVY_TPURGE

This field specifies, for non-VTAM terminals only, whether the transaction can be purged because of a terminal error. Field value: Yes or No.

RCVY_WAIT

This field specifies whether an in-doubt unit of work (UOW) is to wait, pending recovery from a failure that occurs after the UOW has entered the in-doubt state. Field value: Yes or No.

RCVY_WAITTIME

This field specifies how long a transaction waits for an in-doubt unit of work before taking the action specified in the ACTION attribute. RCVY_WAITTIME is used only if RCVY_WAIT=Yes.

- **00,00,00** - The transaction waits indefinitely.
- **dd,hh,mm** - The time, in days, hours, and minutes, for which the transaction is to wait. The maximum value is 93,23,59.

RESOURCE

This field specifies the resource name that is used to secure the CICS transaction. Maximum length: 246 characters. Default length: 13 characters.

RESOURCE_LOCATION

This field indicates the environment where the resource is relevant. This field is the concatenation of several fixed strings, fields and lookups, such as: *system*.CICS.*jobname*.TRN. An example value is IPO1.CICS.CICSTS41.TRN. Maximum length: 30 characters.

RMT_DYNAMIC

This field specifies whether the transaction can be dynamically routed to a remote CICS region. Field value: Yes or No.

RMT_NAME

This field specifies the name by which the transaction is known in the remote CICS region. Maximum length: 8 characters.

RMT_ROUTABLE

This field specifies whether the transaction is the subject of an eligible EXEC CICS START command, it will be routed using the enhanced routing method. Field value: Yes or No.

RMT_SYSTEM

This field specifies the name of a remote CICS region to which the transaction attach request is sent. Maximum length: 8 characters.

RMT_TRANPROF

This field specifies the name of the profile for the session that carries intersystem flows during ISC transaction routing. Maximum length: 8 characters.

SEC_CMD

This field specifies whether command security checking is to be used for resources accessed by this transaction. If the value is Yes, an external security manager, such as RACF, is used. Field value: Yes or No.

SEC_RES

This field specifies whether resource security checking is to be used for resources accessed by this transaction. If the value is Yes, an external security manager, such as RACF, is used. Field value: Yes or No.

STEPNAME

This field contains the step name associated with the CICS region. Maximum length: 8 characters.

SYSIDNT

This field specifies a 1-to 4-character name to identify your local CICS region. Maximum length: 4 characters.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. The field length is 8 characters for compatibility with other NEWLIST types. Maximum length: 8 characters.

TRACE

This field specifies whether the activity of this transaction is to be traced. Field value: Yes or No.

TRACE_CONFDATA

This field specifies whether CICS is to suppress user data from CICS trace entries. Field value: Yes or No.

TRAN_ALIAS

This field specifies an alias transaction name for this transaction. Maximum length: 4 characters.

TRAN_CLASS

This field specifies the name of the transaction class that the transaction belongs to. A transaction class imposes scheduling constraints on transaction execution. Maximum length: 8 characters.

TRAN_ISOLATION

This field specifies whether CICS isolates the transaction's user-key task-lifetime storage in order to provide transaction-to-transaction protection. Field value: Yes or No.

TRAN_PROFILE

This field specifies the name of the profile definition that specifies the processing options used in conjunction with the terminal that initiated the transaction. Maximum length: 8 characters.

TRAN_SHUTDOWN

This field specifies whether the transaction is able to run during CICS shutdown. Field value: Yes or No.

TRAN_TASKREQ

This field specifies whether a transaction is to be initiated by pressing a PF key, by using a light pen, or by using a card. The possible values are as follows:

- **PA1, PA2, or PA3** for PA keys.
- **PF1 through PF24** for PF keys.
- **OPID** for the operator identification card reader.
- **LPA** for a light-pen-detectable field on a 3270 device.
- **MSRE** for the 10/63 character magnetic slot reader.

TRAN_TPNAME

This field specifies the name of the transaction that might be used by an APPC partner if the 4-character length limitation of the TRANSACTION attribute is too restrictive. Maximum length: 64 characters.

TRAN_XTRANID

This field specifies another name to be used to initiate transactions instead of the transaction name. The name might be up to 8 hexadecimal digits in length.

TRANSACTION

This field specifies the name of the CICS transaction. Maximum length: 4 characters.

TWASIZE

This field specifies the size (in bytes) of the transaction work area to be acquired for this transaction. The possible values are: 0 to 32767.

VTAM_APPLID

This field specifies the specific VTAM application identifier (APPLID) for the CICS region. Maximum length: 8 characters.

CLASS: RACF Class Descriptor Table

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
				•	•	•

This section documents the fields for the CLASS NEWLIST. Unless otherwise stated, all fields can be used for SELECT or EXCLUDE processing as well as in the output commands (LIST, SORTLIST, DISPLAY, and SUMMARY).

IBM ships the definition of many classes in an assembled module called ICHRRCDX, the IBM-part of the Class Descriptor Table (CDT). The classes included in the CDT are known as *standard classes*. An installation can add classes to RACF in an assembled module called ICHRRCDE. The classes in this module are known as *user-defined classes*, although many of them are mandated by third-party products. Together, the ICHRRCDX and ICHRRCDE modules are called the static CDT.

Classes can also be defined dynamically, using profiles in the class CDT in z/OS release 1.6 and later. Through the CDTINFO segment, each CDT profile describes a dynamic class. A CDT profile cannot redefine a class defined in the static CDT. In order to avoid potential name conflicts with classes in the ICHRRDCX module, use at least one numeric or national character (#, @, $) in the names of your classes. A warning is issued if you create a profile definition without one of these characters, but the profile is still created. However, if a name conflict occurs, the definition in the ICHRRCDX module takes precedence over any user-defined definition.

The CLASS NEWLIST combines the Class Descriptor Table (CDT) and class-specific SETROPTS options as RACF is using them, which is represented by the incore bits as they are captured in the CKFREEZE snapshot for each system. This class also has additional fields with profile counts that are read from the RACF database if any of those fields are requested. The CLASS NEWLIST provides an alternative to the built-in SHOW CLASSES report. This NEWLIST generates one entry per class in the CDT per system. SYSTEM CLASS is not a guaranteed unique key because a single system can have the same class in both the static CDT and in CDT profiles, which is an acceptable configuration during a short migration period. A single system can also have duplicate profiles within the static CDT, which is considered an error.

The DATASET class is not part of the CDT. For completeness it is shown using a simulated CDT record. Class activity options for the DATASET class are included in this simulated CDT record. They can also be displayed with NEWLIST TYPE=SYSTEM.

Field descriptions

The CLASS NEWLIST provides the following fields for reporting.

ACTIVE

RACF protection for this class is active as a result of a SETROPTS CLASSACT command. This field supports overtype.

AUDIT

Command auditing for this class is active as a result of a SETROPTS AUDIT command. This field supports overtype.

AUDITCONCERN,CONCERN

This field returns a concatenation of audit concerns for the class. The following table shows the default audit priority when active and when not active and provides a description of the associated audit concern. It is sorted by highest audit priority without a policy statement.

Table 325. Default audit priority values and descriptions for active and inactive

Active	Inactive	Audit concern
35	3	SAF calls not processed (not in router table)
35	2	Generics present but not used
25	15	GENCMD off but GENERIC on
	24	Operators are completely unrestricted, no granularity / not B1 compliant
	23	No protection against hackers masquerading as app to steal pwd / not B1 compliant
	22	No protection against hackers masquerading as TP server to steal info / not B1 compliant
	22	Devices like ESCON directors, FEPs, local terminals unprotected / not B1 compliant
	21	No granularity in securing LLA and system services / not B1 compliant
20	20	*settings* difference between database and storage
	20	Temporary data sets resident after failure are unprotected / not B1 compliant
15	3	UACC greater than READ
15	2	GENCMD on but GENERIC off
15	2	Violations not logged - LOGOPTIONS(NEVER)
15	1	UNIX ID uniqueness not enforced by SHARED.IDS profile
15		UNIX options not active because class not RACLISTed
	12	Spooled output not subject to RACF controls / not B1 compliant
11	2	Profile changes in class are not audited
	10	TSO authorities not controlled through RACF, no audit trail / not B1 compliant
	10	JES local node cannot be determined by RACF, spool offload unusable / not B1 compliant
10	1	OPERATIONS honored
10	1	Default RACMAP filter maps to unrestricted user ID
6	1	Default RACMAP filter maps to unprotected user ID
5	1	UACC based on connect group
5	1	UACC greater than NONE
5	1	SETROPTS GLOBAL inactive, but profile present
	5	Profile present but class inactive
1	1	UACC greater than NONE (IBM default)
1	1	UACC based on connect group (IBM default)
1	1	OPERATIONS honored (IBM default)
1	1	Installation defined
	0	Message receivable not subject to MAC / not B1 compliant
	0	Prints are not labelled / not B1 compliant
	0	Security labels are not used / not B1 compliant
	0	Message exchange not controlled / not B1 compliant

Table 325. Default audit priority values and descriptions for active and inactive (continued)

Active	Inactive	Audit concern
	0	Input devices must have a defined security label / not B1 compliant
0		DASDVOL does not implement MAC / not B1 compliant
0	0	No mandatory logging / not B1 compliant

The priority is 40 higher if the concern is not compliant to the policy that has been selected. A priority of 0 means the concern is not issued unless the policy has explicitly been requested.

The following audit concerns have been defined:

- **DASDVOL does not implement MAC / not B1 compliant**

  The DASDVOL class is active on this system. DASDVOL does not honor security labels, and should as such not be used on a B1 compliant system.
- **Devices like ESCON directors, FEPs, local terminals unprotected / not B1 compliant**

  When the DEVICES class is inactive, there is no control over which users can allocate unit record devices, teleprocessing or communications devices, and graphics devices.
- **GENCMD off but GENERIC on**

  For this class the generic command processing has been turned off, while the class is being used as a generic class. Newly created profiles would turn out to be DISCRETE profiles, even if they contain generic characters. This situation should not occur.
- **GENCMD on but GENERIC off**

  The creation and deletion of generic profiles is possible, but RACF does not use them for access control. This could lead to data that is unprotected against expectations. This situation is intended for use when migrating from discrete profiles to generic profiles.
- **Generics present but not used**

  This discrete class contains generic profiles. These profiles are not used by RACF. These profiles can be deleted after turning on generic command processing for the class, using SETROPTS GENCMD(class).
- **Input devices must have a defined security label / not B1 compliant**

  The TERMINAL class is not active. For B1 compliancy it is necessary for each terminal to have a security label defined, so only appropriate data can be accessed via each terminal. This allows better physical security around highly sensitive data access.
- **Installation defined**

  This class is installation defined. Though not necessarily dangerous, this class warrants extra alertness in comparison to defined IBM classes.
- **JES local node cannot be determined by RACF, spool offload unusable / not B1 compliant**

  The &RACLNDE profile in the RACFVARS class is necessary for spool reload functions.
- **Message exchange not controlled / not B1 compliant**

The SMESSAGE class can be used to control which users or groups can send messages to which users. When the SECLABEL class is active, automatic checking of the security label set by the sender against that of the receiver is done as well.

- **Message receipt not subject to MAC / not B1 compliant**

  The DIRAUTH class can be used to block users from receiving any messages with a `seclabel` higher than the one with which they logged on. This also enables auditing of message receipt.

- **No granularity in securing LLA and system services / not B1 compliant**

  In the FACILITY class the possibility exists to define profiles to control access to Library LookAside managed data sets and multiple system services.

- **No mandatory logging / not B1 compliant**

  An access to a profile in the class is not always logged. The concern applies to the DEVICES, DIRAUTH, JESSPOOL, OPERCMDS, PSFMPL, and SMESSAGE classes. It reflects the SETROPTS LOGOPTIONS(ALWAYS(CLASS)) setting.

- **No protection against hackers masquerading as app to steal pwd / not B1 compliant**

  When the VTAMAPPL class is inactive, there is no control over which users can open the application control block (ACB) indicated by a VTAM application program.

- **No protection against hackers masquerading as TP server to steal info / not B1 compliant**

  When the APPCSERV class is inactive, you cannot ensure that only authorized server programs are allowed to serve a particular TP.

- **`OPERATIONS` honored**

  Granting userids with OPERATIONS access to resources within this class, by default, is dangerous and might expose resources in an unintended fashion. Carefully review the need for this class to allow OPERATIONS.

- **`OPERATIONS` honored (IBM default)**

  Granting userids with OPERATIONS to access to resources within this class, by default, is dangerous and might expose resources in an unintentional fashion. Even though it is the IBM default for this class, a careful review might be appropriate.

- **Operators are completely unrestricted, no granularity / not B1 compliant**

  When the OPERCMDS class is inactive, anyone at a master console or a console with system authority is able to use all operator commands.

- **Default RACMAP filter maps to unrestricted user ID**
  Default RACMAP filter maps to unprotected user ID

  Based on the RACF security guidelines, a default RACMAP filter must be mapped to a RACF user ID that is restricted and protected. The default RACMAP filter applies to any user ID in any registry that does not match a more specific filter. Mapping the default filter to a restricted `userid` prevents granting too much access to web users. Mapping the default filter to a protected `userid` prevents locking users out because of an expired password, and prevents the userid from being revoked by a Denial-of-Service attack using the wrong passwords.

- **Prints are not labelled / not B1 compliant**

  If Print Services Facility/MVS (PSF/MVS) is installed, the PSFMPL class can be used to force labeling of all prints and granting the possibility of overriding this to selected users.

- **Profile changes in class are not audited**

  Changes to profiles in the class (by using the RDEFINE, RALTER, RDELETE, and PERMIT commands) are not always logged. This concern reflects the SETROPTS AUDIT(CLASS) setting.

  Note that profile changes are logged if SPECIAL users execute the commands while the SETROPTS SAUDIT setting is active.

- **Profile present but class inactive**

  The SAF (System Authorization Facility) router returns the default return code from the CDT (most often RC=4, which indicates an indeterminate result) for any SAF check in these classes, and RACROUTE calls do not use profiles in these classes. RACF can use these profiles using the RACHECK interface, leading to conflicts between SAF and direct RACF calls.

- **SAF calls not processed (not in router table)**

  This class is not found in the router table. This means that RACF returns the "not protected" return code. Most applications grant access in this situation. On z/OS V1R6 and higher systems the router table is optional, and this audit concern is no longer generated.

- **Security labels are not used / not B1 compliant**

  The security label system (SECLABEL class) can be used to dramatically increase the granularity of access control throughout your system. It is one of the basics of B1 security.

- **`SETROPTS GLOBAL` inactive, but profile present**

  This suggests that somebody wanted to add entries for this class to the global access table, but did not succeed in doing so.

- *`settings`* **different between database and storage**

  This indicates that the indicated settings in the system's RCVT (the actual in-storage bits being tested by RACF) differ from the settings stored on DASD in the RACF database ICB. This is probably caused by combining a CKFREEZE file and RACF database of different systems or by combining snapshots of different dates or time. Although less likely, it can also be caused by an attacker changing the in-storage settings. The value *settings* can be one or more of the following: STATS, AUDIT, ACTIVE GENERIC, GENCMD, GLOBAL, RACLIST, GENLIST, LOGALWAYS, LOGNEVER, LOGSUCCESS, and LOGFAILURE.

- **Spooled output not subject to RACF controls / not B1 compliant**

  The JESSPOOL class can be used to control all JES2 or JES3 spool files. When activating this class, the default is that only the user who created the spool file has any access to it, but profiles can be created to allow others access.

- **Temporary data sets resident after failure are unprotected / not B1 compliant**

  The TEMPDSN class is inactive. After activating this class, only users with the OPERATIONS attribute have access to temporary data sets left after a system failure, and then only to scratch these data sets. With TEMPDSN inactive these data sets are completely unprotected by RACF and most applications grant access in this case.

- **TSO authorities not controlled through RACF, no audit trail / not B1 compliant**

  Any one of the classes ACCTNUM, TSOPROC, or TSOAUTH is not active. This means that for access to these resources, TSO/E uses the information as stored in SYS1.UADS. RACF control and auditing are not possible for account numbers, logon procedures, and most TSO authorizations. In this situation,

the CONSOLE, PARMLIB and TESTAUTH functions are not available. Auditing of the TSOAUTH authorizations, except for the PARMLIB command is always suppressed by TSO/E.

- **UACC based on connect group**

  Whenever you create a profile in this class and do not specify an explicit UACC the UACC is copied from the current connect group. This means it depends on which userid and group name a user specified at logon time. Hence it is rather easy to issue a UACC too that is too high by mistake.

- **UACC based on connect group (IBM default)**

  Whenever you create a profile in this class and do not specify an explicit UACC the UACC is copied from the current connect group. This means it depends on which userid and group name a user specified at logon time. Hence it is rather easy to issue a UACC too that is too high by mistake.

- **UACC greater than NONE**

  Setting the default access level higher than NONE is not advised. Although this setting might be appropriate in some circumstances, it is a good idea to review the setting to ensure that resources are not accidentally exposed to unnecessary read access.

- **UACC greater than NONE (IBM default)**

  Setting the default access level higher than NONE is not advised. Although this setting is the IBM default, it is a good idea to review the setting to ensure that no sensitive data is accidentally exposed.

- **UACC greater than READ**

  It is unusual for a protected resource to have default access above READ, although NONE is preferable. This might be appropriate, but bears a review to ensure that resources are not accidentally exposed to update or greater access.

- **UNIX ID uniqueness not enforced by SHARED.IDS profile**

  To control the use of shared IDs, a resource profile called SHARED.IDS can be defined in the UNIXPRIV class. When this profile is absent the use of shared user and group IDs is not protected.

- **UNIX options not active because class not RACLISTed**

  The UNIXPRIV class has to be RACLISTed for the profiles in this class to be used.

- **Violations not logged - LOGOPTIONS(NEVER)**

  This is undesirable since violations would not be journaled to SMF. Journaling violations and follow-up tracking is critical to securing the resources within an installation.

AUDITPRIORITY

This field returns the audit priority for the concern. See field AUDITCONCERN for a table with the concerns and their priorities. The actual audit priority can be higher or lower because of differences between classes and e.g. a SIMULATE POLICY C2 statement.

CASE_ASIS

This flag field indicates whether profile names for this class are kept as is or are converted to upper case. This field has a flag format where "Yes" means that the case is preserved, and "No" means that names are converted to uppercase. For very old RACF systems, the value is blank. This also means that names are converted to uppercase.

CLASS, C

Class name of current entry.

CLASSNO

This is an alias of ORG.

CLAUTH

The class authorization field CLAUTH is a repeating field that includes the eight-character RACF user IDs that can administer the specified class. These user IDs include those that have a class with the same POSIT number as the specified class in their CLAUTH list, although they do not specifically have the class on the CLAUTH parameter. The CLAUTH authority can be limited by the SETROPST GENERICOWNER specification. However, for classes that have an associated grouping class that is RACLISTed, a CLAUTH user can subsume any generic general resource profile with a discrete profile that does not exist yet as a member profile or a group profile member–independently of the GENERICOWNER setting.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. This value can come from the ALLOC COMPLEX parameter or default to a system name.

DATASPC

This flag indicates whether RACLISTed profiles for this class have been stored in a dataspace.

DESCRIPTION

This 64 character field returns a short explanation of the purpose of the class.

DFLTRC

This field contains the default return code for this class. This code is returned when no matching profile can be found at a RACHECK. The result codes and their meaning are documented in the following table.

Table 326. Result code values and descriptions

DFLTRC value	Meaning
0	Allow access
4	Indeterminate: depends on resource manager
8	Fail access

EQUALMAC

This flag field indicates whether equal mandatory access checking is required for resources in this class. This means that in order to be granted access to a resource, the SECLABEL of the user and the resource must be equivalent (have the same security level and categories). This setting is used only when the SECLABEL class is active.

GEN

This string is set to '**Discrete**' if generic profiles in this class are not checked, and is empty otherwise.

GENCMD

Generic profile command processing for this class is active (due to a SETROPTS GENCMD or a SETROPTS GENERIC command). This field supports overtype.

GENERIC

Generic profile checking for this class is active (due to a SETROPTS GENERIC command). This implies that generic command processing for this class is active. This field supports overtype.

GENERIC_ALLOWED

Flag field that indicates whether SETROPTS GENERIC and SETROPTS GENCMD are authorized for the class. The value corresponds to the CDTGEN field in the `RACF NEWLIST (NEWLIST TYPE=RACF)` , see "CDTGEN" on page 1137.

GENLIST

This flag indicates that this class has been GENLISTed, which means that generic profiles for this class are retained in storage that is shared between address spaces based on a SETROPTS GENLIST command. If this flag is set, the RACLIST flag cannot be set. This field supports overtype.

GENLIST_ALLOWED

Flag field that indicates whether this class can be GENLISTed. That is, generic profiles for this class can be retained in storage that is shared between address spaces (by using the SETROPTS GENLIST command).

GLB

String indicating global access checking activity. Note that for older RACF versions, global access checking and SETROPTS RACLIST cannot be combined; if this appears to be the case, this string is set to `n/a`. Otherwise, it is set to `Glob` if global access checking is active, and blank if global access checking is inactive.

GLOBAL

Flag indicating Global Access Checking activity. Undefined if no Global Access checking is allowed, set if Global Access checking is active, and not set if Global Access checking is inactive. This field supports overtype.

ID

Generic class identifier. This is a number in the range 0 to 255 that is associated with the class name in the Class Descriptor Table and also stored in the CLASTYPE field of general resource profiles in the RACF database. Numbers 1 through 127 are reserved for use by IBM; numbers 128 through 255 are installation-dependent.

INRFR

This flag indicates whether the current class is included in the SAF (System Authorization Facility) router table (see NEWLIST TYPE=ROUTER). On z/OS V1R6 and higher systems the router table is optional. On those systems a 'No' is interpreted as if an entry with ACTION=RACF were present. On older systems any 'No' indicates a mismatch and RACROUTE requests for this class return an 'indeterminate' result (RC=4).

INSTALLATION_DEFINED

This flag indicates whether the class is user-installed (for example, not IBM-defined).

LOGOPT

Auditing options for this class, due to a SETROPTS LOGOPTIONS command. The LOGOPT values and the SETROPTS LOGOPTIONS auditing level are documented in the following table.

LOGOPT value	SETROPTS LOGOPTIONS auditing level
Always	ALWAYS
Failure	FAILURES
Never	NEVER
Profile	(determined by profile)
Success	SUCCESSES

This field supports overtype.

MAXLEN

This field contains the maximum length of profile names in this class. This is a number in the range 1 to 246. See also MAXLEN_ENTITY.

MAXLEN_ENTITY

This field specifies the backward compatible maximum profile name length to be used with the ENTITY keyword form of the RACROUTE macro. This macro form does not pass the return buffer length; if the maximum profile name length increases, existing applications might break if the entire profile names were returned. IBM recommends that the ENTITYX keyword form of RACROUTE is used, to which this limit does not apply. This is a number in the range 1 to 246; the default is 8. See also MAXLEN (the true maximum profile name length).

NOPROF

Flag indicating whether profile definition is forbidden in this class. If set, users cannot use the RDEFINE command to define profiles.

NUMDISC

Number of discrete profiles in this class.

NUMGEN

Number of generic profiles in this class.

NUMPROF

Number of profiles in this class (NUMDISC plus NUMGEN).

OPER

This flag field indicates whether OPERATIONS authority is honored for this class.

OPEROPER

This is a string representation of the OPER field. It contains the text '**OPER**' if OPERATIONS authority is honored for this class, and is empty otherwise.

ORG, ORDER, CLASSNO

The original order (entry number) of this class in the class descriptor table. The first entry in the table has ORDER=1.

POSIT

This field contains the options set id, a number in the range 0 to 1023 identifying a set of SETROPTS options that govern the activity of this class and all other classes having the same POSIT value. Whenever a SETROPTS command is issued for any class with a specific POSIT value, it applies to all classes with that same POSIT.

POSIT values in the range 0-18, 57-127, and 528-1023 are reserved for use by IBM; numbers 19-56 and 128-527 are installation-dependent.

PROTECT

This is a string summarizing the protection options for this class and is based on the ACTIVE and AUDIT flags. The PROTECT values and the related values of the ACTIVE and AUDIT flags are documented in the following table.

Table 327. PROTECT value descriptions and associated flags

PROTECT value	ACTIVE flag	AUDIT flag
Inactive	NO	-
Noaudit	YES	NO
(blank)	YES	YES

QUAL

This field contains the number of qualifiers at the start of the profile name that cannot be generic. This is a number in the range 0 to 123; the default is 0. During access verification, RACF ignores all profiles that have generic characters in the specified number of qualifiers. This also controls which profiles are loaded (and kept) in storage.

RACLIST

This flag indicates that this class has been RACLISTed, which means that both generic and discrete profiles for this class are loaded into storage that is shared between address spaces (due to a SETROPTS RACLIST(class) command). If this flag is set, the GENLIST flag cannot be set. This field supports overtype.

RACLIST_ALLOWED

Flag field that indicates that this class can be RACLISTed by issuing the SETROPTS RACLIST command. When a class is RACLISTed, both discrete and generic profiles are loaded into storage that is shared between address spaces. Generally, this flag is turned off if only an application is supposed to request a RACLIST. See also RACLREQ and RACLIST_GBL_ONLY.

RACLIST_GBL_ONLY

Flag field that indicates that this class is currently RACLISTed to a dataspace only because an application issued a `RACROUTE REQUEST=LIST` with `GLOBAL=YES`. Applications like CICS and IMS use this function to allow efficient use of `RACROUTE REQUEST=FASTAUTH` for checking user authorizations. For SETROPTS RACLISTed resource classes, RACF issues a warning message if a `SETROPTS RACLIST REFRESH` is required for the resource class to make the changes effective. RACF does not issue such a warning message for `GLOBAL ONLY RACLISTed` resource classes. Although RACF does not issue the warning, you still need to issue the `REFRESH` to make changes to such a class effective.

When applicable, this flag is set for grouping and member classes.

RACLREQ

Flag field That indicates that this class must be RACLISTed. When a class is RACLISTed, both generic and discrete profiles are loaded into storage that is shared between address spaces.

RVRSMAC

This flag field indicates whether reverse mandatory access checking is required for resources in this class. This means that the SECLABEL of the resource must dominate the SECLABEL of the user. This setting is used only when the SECLABEL class is active. See also EQUALMAC.

SAME_POS

This repeated field contains the classes that have the same POSIT value as this class. Whenever a SETROPTS command is issued for any class with a specific POSIT value, it applies to all classes with that value. This field lists all classes in the CDT, not only the active ones.

SECLABEL

This flag field indicates whether security labels are required for resources in this class. When the SECLABEL class is active and a security label exists for a resource, the security label for the resource is used during authorization checking, even when security labels are not required.

SIGNAL

This flag field indicates whether an ENF signal must be sent when the class is being RACLISTed, NORACLISTed, or RACLIST REFRESHed.

STATS

Flag indicating whether statistics are collected for this class (due to a SETROPTS STATISTICS command). This field supports overtype.

SYN1ALP

Flag field that indicates if the first character of a profile in this class can be alphabetical. Combine this flag with the SYN1NAT, SYN1NUM and SYN1SPE flags to determine all legal first characters.

Note: These flags do not match the input parameters used to build the Class Descriptor Table. The following table documents the input parameter values and their correspondence to the SYN1ALP, SYN1NAT, SYN1NUM and SYN1SPE flags and the combination field SYN1RAW

Table 328. Input parameters values and character flag settings

Input value	SYN1ALP	SYN1NAT	SYN1NUM	SYN1SPE	SYN1RAW
ALPHA	Yes	Yes	No	No	C0
ALPHANUM	Yes	Yes	Yes	No	E0
ANY	Yes	Yes	Yes	Yes	F0
NONATABC	Yes	No	No	No	80
NONATNUM	Yes	No	Yes	No	A0
NUMERIC	No	No	Yes	No	20

SYN1NAT

Flag field that indicates if the first character of a profile can be a national character (#, @ and $). Combine this flag with the SYN1ALP, SYN1NUM and SYN1SPE flags to determine all legal first characters. See also the table at the SYN1ALP field.

SYN1NUM

Flag field that indicates if the first character of a profile in this class can be a numeric character. Combine this flag with the SYN1ALP, SYN1NAT and SYN1SPE flags to determine all legal first characters. See also the table at the SYN1ALP field.

SYN1RAW

This field contains the raw value of the syntax rules for first character of profile in this class. It is a combination of the corresponding flags SYN1ALP, SYN1NAT, SYN1NUM and SYN1SPE. To interpret the value of this field, see also the table at the SYN1ALP keyword.

SYN1SPE

Flag field that indicates if the first character of a profile in this class can be a special character–any character other than alphabetical, numerical, national, blank, comma, parenthesis or semicolon. Combine this flag with the SYN1ALP, SYN1NAT and SYN1NUM flags to determine all legal first characters. See also the table at the SYN1ALP field.

SYNRALP

Flag field that indicates if all characters other than the first character of a profile in this class can be alphabetical. Combine this flag with the SYNRNAT, SYNRNUM and SYNRSPE flags to determine all legal characters.

Note: These flags do not match the input parameters used to build the Class Descriptor Table. The following table documents the input parameter values and their correspondence to the SYNRALP, SYNRNAT, SYNRNUM and SYNRSPE flags and the combination field SYNRRAW.

Table 329. Input parameter values and character flag settings

Input value	SYNRALP	SYNRNAT	SYNRNUM	SYNRSPE	SYNRRAW
ALPHA	Yes	Yes	No	No	C0
ALPHANUM	Yes	Yes	Yes	No	E0
ANY	Yes	Yes	Yes	Yes	F0
NONATABC	Yes	No	No	No	80
NONATNUM	Yes	No	Yes	No	A0
NUMERIC	No	No	Yes	No	20

SYNRNAT

Flag field that indicates if all characters other than the first character of a profile in this class can be a national character (#, @ or $). Combine this flag with the SYNRALP, SYNRNUM and SYNRSPE flags to determine all legal characters. See also the table at the SYNRALP field.

SYNRNUM

Flag field that indicates if all characters other than the first character of a profile in this class can be a numeric character. This flag must be combined with the SYNRALP, SYNRNAT and SYNRSPE flags to determine all legal characters. See also the table at the SYNRALP field.

SYNRRAW

Contains the raw value of the syntax rules for the remainder characters of a profile name in this class. It is a combination of the corresponding flags SYNRALP, SYNRNAT, SYNRNUM and SYNRSPE. To interpret the value of this field, see the table at the SYNRALP field.

SYNRSPE

Flag field that indicates whether all characters other than the first character of a profile in this class can be a special character–any character other than alphabetical, numerical, national, blank, comma, parenthesis, or semicolon. Combine this flag with the SYNRALP, SYNRNAT and SYNRNUM flags to determine all legal first characters. See also the table at the SYNRALP field.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. The field length is 8 characters to cater to VM systems.

UACC

This field contains a character string with the default Universal ACCess for this class. This default UACC is used to set the profile UACC during addition of a profile in this class if no UACC is specified on the command. Possible UACC values are documented in the following table. The special value ACEE indicates that the value UACC is taken from the default UACC in the user's ACEE (specified by UACC on the ADDUSER, ALTUSER or CONNECT command.) Table 330 lists the possible UACC field values in descending sort order. Because this is a string field, the statement SELECT UACC>=UPDATE can return undesired results. Use SELECT UACC=(UPDATE,CONTROL,ALTER) instead.

Table 330. Possible UACC values

UACC value
ACEE
ALTER
CONTROL
NONE
READ
UPDATE

WHERE

This field indicates profile residency. The possible WHERE values and their meaning are documented in the following table.

Table 331. WHERE values and descriptions

WHERE value	Meaning
Genlist	Profiles have been GENLISTed as a result of a SETROPTS GENLIST command. That is, generic profiles are retained in storage shared between address spaces, but discrete profiles are not resident.

Table 331. WHERE values and descriptions (continued)

WHERE value	Meaning
NoGenl	SETROPTS GENLIST is not allowed for this class; SETROPTS RACLIST is, but has not been specified.
NoList	SETROPTS RACLIST and SETROPTS GENLIST are not allowed for this class, usually because applications issue RACLIST themselves.
NoRacl	SETROPTS RACLIST is not allowed for this class; SETROPTS GENLIST is, but has not been specified.
Nowhere	Profiles not allowed in this class.
RaclGbO	The profiles are resident only because they have been RACLISTed by an application via a RACROUTE macro with GLOBAL=YES specified.
Raclist	Profiles have been RACLISTed (due to a SETROPTS RACLIST command), for example reside in a data space or in (E)CSA.
RaclReq	Profiles must reside in-storage if class is active.
(blank)	Class has not been RACLISTed or GENLISTed, but it would be allowed.

XCLASS

Contains the name of the related class. This field only returns a value for grouping or member classes.

XGROUP

For member classes, this field contains the name of the related grouping class. For non-member classes this field is blank. See also XMEMBER.

XMEMBER

For grouping classes, this field contains the name of the related member class. For non-grouping classes this field is blank. See also XGROUP.

CONCERN_TEXT: Concern translation properties

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The CONCERN_TEXT NEWLIST (NEWLIST TYPE=CONCERN_TEXT) enumerates text segments used in audit concern text and is useful to translate audit concern text. It is only supported if zSecure Audit is installed and active.

The default title for this report is: AUDIT CONCERN TEXT DEFINITIONS.

Field descriptions

You can use the following CONCERN_TEXT fields to translate the audit concerns.

CONCERN

Final translated text of the audit concern. Variables can occur in a different place then in the English string.

CONCERN_ID

Unique identification of the concern.

CONCERN_ORIG

The original (English) text for the audit concern. Variables are preceded with a number symbol (#) and end with a period, for example, #1..

NEWLIST_TYPE

The TYPE passed on the NEWLIST statement, optionally suffixed with .DISPLAY if the NEWLIST contains a DISPLAY or DSUMMARY statement, as opposed to only a subset LIST, SORTLIST, or SUMMARY statement.

The key for records of this type is CONCERN_ID.

NEWLIST_TAG

An internal number for the NEWLIST type. This value can change without warning and should not be used as a programming interface.

CONSOLE: System Consoles

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The CONSOLE NEWLIST (NEWLIST TYPE=CONSOLE) describes the system consoles defined on the target systems. Each entry in this NEWLIST represents one console. EMCS consoles are only present when the CKFREEZE data has been collected from an APF-authorized run of zSecure Collect.

Field descriptions

The CONSOLE NEWLIST provides the following fields for reporting.

ACTIVE

Flag field that indicates whether the console is active or not. For a subsystem console, it is shown as Yes when the console is dedicated to a subsystem, and No if it is in allocatable status.

ALTERNATE

This field describes the name of the alternate console, or the console group that will serve as an alternate. It contains the alternate console group (ALTGRP), or the alternate console's name (possible until z/OS 1.4), or has the format **xxx** or **xxx,xxx** describing the alternate console's device number(s). This field is 9 characters in length.

This field is not present in z/OS V1R8 and higher systems.

AUDITCONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field. The AUDITCONCERN field can contain one or more concerns separated by commas. The following audit concerns are currently defined:

Table 332. Audit concern priority descriptions

Active	Inactive	Meaning

Table 332. Audit concern priority descriptions (continued)

25	65	**System authority and no logon required, any terminal may connect (SMCS LU not predefined)** This concern indicates that an explicit LOGON must be specified in CONSOL*xx* because the default for non-predefined SMCS consoles is to use LOGON=REQUIRED. This condition is unsafe condition because any terminal can issue a LOGON APPLID for the SMCS VTAM application, and operator commands can be issued without the user being authenticated. It then depends on the SAF (System Authorization Facility) class OPERCMDS to determine exactly which commands are permitted or disallowed. This is a violation of B1 policy.
20	60	**System authority and no logon required** The console's authority includes system commands, but the system does not require logons for any console. You should check that the console, the alternate console, and all subsequent alternate consoles, reside in a secure area. This must condition can only be created by an explicit LOGON specification in CONSOLxx, since the default for non-predefined SMCS consoles is to use LOGON=REQUIRED. It depends on the SAF class OPERCMDS exactly which commands are allowed or disallowed. This is a violation of B1 policy.
15	55	**Any terminal may connect and is logged on automatically without authentication (SMCS LU not predefined)** This SMCS console is available to any terminal (LU) and automatically logs on with a RACF userid equal to the console name without requiring authentication. The OPERCMDS class restricts what commands can be issued.
5	5	**No logon required, any terminal may connect and obtain information (SMCS LU not predefined)** This SMCS console is available to any terminal (LU) and does not require a LOGON. The console does not have the authority to issue commands that require SYSTEM or MASTER authority, but it allows commands that display information. This can help a hacker in obtaining inside information like lists of userids he can then to guess passwords for.
2	2	**Autologon specified but RACF user undefined** The console will not function. It is not a security risk but a housekeeping issue, unless the console has a critical role for some reason.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 333. CONSOLE NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

AUTH

This field describes the AUTH parameter of the console, which specifies the MVS command groups to be executed. This is a string that can contain one or more of the values SYS, IO, CONS, and INFO; if all values are set, the string has the value ALL. For a master console, this string has the value MASTER.

Table 334. AUTH values and descriptions

AUTH value	Meaning
ALL	All command types
CONS	Console commands
INFO	Information commands
IO	Input/output commands
MASTER	Master console
SYS	System commands

Note: This field is implemented as a text string with assigned positions for the possible values. So if a console has only INFO authority the value displayed will be "_____INFO", while a console with both CONS as well as INFO authority will be displayed as "_____CONS INFO" (underscores are used to denote blanks). When a console has all four possible authorizations the string "ALL_____" is used instead of the list of four authorizations. When searching for the consoles that have a particular authority, you should use a list of values. The first two are "ALL" and "MASTER". The other one could use the scan operator ":" or the substring function. Using these three values, you will find all consoles that have the required authorization. For example, to find all consoles with an authorization including "IO", you could use SELECT AUTH=(:IO,ALL,MASTER).

AUTO

Flag field that indicates whether this console is to receive messages that were automated (and possibly suppressed) by the Message Processing Facility (MPF). It is only defined for EMCS consoles. To see which messages are automated, see NEWLIST TYPE=MSG.

CMDSYS

The system that will receive commands typed on the console. It can be "*" to indicate the system where the console is defined. This field length is 8 characters.

CNID

This is the 4 byte console id. It is displayed in hexadecimal by default. It is the id used by programs to route commands responses or messages.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. The complex name can come from the ALLOC COMPLEX parameter or default to a system name.

CONSOLE_NO

This field describes the console number. For EMCS consoles, this field is empty, unless they have a migration id defined.

DEVICE_NO, DEVNUM

This field describes the console's device number. It is not present for a subsystem or EMCS console.

DOM

This fields shows whether the console receives Delete Operator Messages (DOM) and from where. It can be ALL (all systems in sysplex), NORMAL (this system), or NONE (no system). This field can be displayed with formats DOM and $DOM.

HC

Flag field that indicates whether this console is to receive hardcopy-only messages. It is only defined for EMCS consoles.

INTIDS

This flag field indicates whether the console should display internal messages (sent to console 0). It is available since z/OS V1R8.

JOBID

This field can contain the JES job id of the job that has the console allocated. It is only defined for EMCS consoles. This field is max 8 characters.

KEY

The KEY assigned by the OPERPARM data to an EMCS console. This key can be set by the creator of an EMCS console or inherited from the OPERPARM specification in the security product. This is just an identifier that a site can use to easily display a set of consoles. It is only defined for EMCS consoles. This field is max 8 characters.

LEVEL

This field describes the message level for the console. It can only be used for output, not for SELECT/EXCLUDE processing. This field contains the console message level in 14 characters. The first 12 characters can be ALL or a combination of the letters R I CE E IN. The last two characters are NB or blank. The length cannot be changed. The field is not present for subsystem consoles. The meaning of the characters is:

Table 335. LEVEL field - character values and descriptions

Character	Meaning
NB	No broadcast messages
ALL	Same as R I CE E IN
R	Messages requiring an operator reply
I	Immediate action messages
CE	Critical Eventual action messages
E	Eventual action messages
IN	Informational messages

LOGON

This field describes whether a logon is required for a console. It can have the values OPTIONAL, REQUIRED, and AUTO.

Note: On pre-z/OS 1.1 systems, this field is the same for all consoles in the system.

LUNAME

For an SMCS console, the VTAM Logical Unit name. For an EMCS console, the terminal name. This field is max 8 characters.

MIGID

Migration id of an EMCS console. This is a small console number that can be used by applications that do not support 4 byte CNIDs yet.

MONITOR

This field shows the events that must be monitored on the consoles, like JOBNAMES, SESSION, and STATUS. It can be displayed with output formats MONITOR and $MONITOR.

NAME

This field describes the console name.

PFKTAB

This field describes the PF-key table used; these tables are defined in SYS1.PARMLIB member PFKTABxx.

RACF_PROFILE

This field shows the profile name for the profile protecting the console. It is blank if there is no such profile or the CONSOLE class is inactive.

ROUTECODE, ROUTCODE

This field describes the routing codes for the console. It can only be used for output, not for SELECT/EXCLUDE processing. The routing code is displayed as a list of routing code ranges, separated by commas.

SUBSYSTEM

This field describes the subsystem to which the console is dedicated, if the TYPE field is set to SUBSYSTEM, and the console is in use by a subsystem. For an EMCS console, this contains the jobname that has the console allocated. In other cases, this field is blank. Maximum length: 8 characters.

As this field mostly contains a jobname the default column header for this field is "Jobname".

SWITCHTO

This field shows the name of a console to which this console has been switched. Normally, it is empty. The field length is 8 characters.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. This field length is 8 characters for compatibility with other NEWLIST types.

TYPE

This field describes the type of the console. It can be:

Table 336. Console TYPE values and descriptions

Character	Meaning
EMCS	An extended (programmatic) console. This value can be a subsystem console (TSO/E, SDSF), syslog, or system console.

Table 336. Console TYPE values and descriptions (continued)

Character	Meaning
Master	The master console (this is an MCS console with master authority).
MCS	A traditional console (MCS means Multiple Console Support).
SMCS	A VTAM console accessed through a VTAM LOGON to a site-specific SMCS application id. SMCS means SNA Multiple Console Support.
SubSystem	A subsystem console. This is a console is allocatable to or allocated by a subsystem like Netview.
Syslog	The SYSLOG EMCS console.
DIDOCS	The DIDOCS EMCS console (DIDOCS means Device Independent Display Of Operator Console Support). This was introduced in z/OS 1.5.

UD

This flag field indicates whether the console displays undirected messages (messages that do not go to a specific console). At least one console in the system should receive these messages.

Note: This field is missing for z/OS 1.5 and higher systems.

UNKNIDS

This flag field indicates whether the console should display messages to unknown console ids. It is available since z/OS V1R8.

USERID

This field provides the `userid` of the user logged on to the console. This field might be blank if no user is logged on to the console–if the LOGON field contains OPTIONAL for example,

CSM: Common Storage

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The NEWLIST TYPE=CSM describes the Common Storage Map. This map shows the memory regions that together form the common (shared) part of virtual storage.

This NEWLIST describes the common storage in detail. Another NEWLIST type, NEWLIST TYPE=VSM, describes the layout of all storage areas, but does not include detailed information on individual common storage areas.

Each entry in this NEWLIST represents a single memory block in common storage, and can be uniquely identified by the fields SYSTEM START.

Field descriptions

The `CSM NEWLIST` provides the following fields for reporting.

AUDITCONCERN

This field indicates the reason for the audit priority. Do not rely on the exact value of this field in your programs. The field content might change. The audit concern currently defined is:

Memory region writable by any user
This audit concern means that an attacker can modify the behavior of an application running in the address space of another user. The amount of damage this situation can cause depends on the application. This situation also highlights that the application has not been designed with proper security in mind. The exposure might be relatively simple to exploit and might compromise the entire system integrity. This problem is obvious if the memory area contains code that is run while in supervisor state or key zero. That latter situation is checked and reported in other `NEWLIST` types like SVC routines, PC routines, subsystem routines, and so on.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 337. CSM NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. This value can be taken from the ALLOC COMPLEX parameter or default to a system name.

END

The end address of a storage area. This value is either an 8 character (4 byte) hexadecimal number or two 8 character hexadecimal numbers separated by an underscore for 8 byte addresses (possibly) situated above the 4 GB threshold.

FPROT

This field is a flag indicating the status of storage fetch-protection for this common storage item. This field returns `Yes` or `No` but its default length is 1 so it returns `Y` or `N` by default. Fetch protection of z/Architecture memory is part of the *key-controlled protection facility* of memory.

Key controlled protection supplies the capability of memory protection (at the 4 K page level). Each running program has a 4 bit key associated with it which is stored in the Program Status Word or PSW. Each page of memory also has 4 bit key associated with it. If these keys match or the PSW key is zero, then the program can both read (fetch) data from the memory and write (store) data back to that memory. If the keys do not match, but the request is for fetch, then a further bit related to the page of memory is examined. This bit is the

Fetch-Protection bit. If the Fetch-Protection bit is set ON, then the access is denied. If the Fetch-protection is off, then the access is granted.

For reference, here are some extra notes to clarify the use of fetch protection:

- 31 bit Common storage is organized into subpools. Some of these subpools are Fetch-protected.
- 64 bit Common memory Objects and Shared Memory Objects can be fetch-protected. Fetch-protection is requested at the time the object is created. While key-protection applies at the page level, z/OS does not supply facilities to have differing keys within a single 64 bit memory object.
- If access to storage is denied during either a fetch or store operation, then a protection exception is raised. z/OS normally presents this condition as a System abend 0C4-04.
- If a program is operating in Key 0, then it is given access (both fetch and store) to all memory by the key-controlled memory protection facility. Because the operating system (z/OS) operates predominantly in Key 0, it is unlikely to suffer fetch-protection issues.
- Programs operating in Keys 0 through 7 are considered privileged by z/OS. Programs operating in these keys can use the MODESET macro to alter their own Key or their program state (Supervisor or Problem Program).
- The following privileged keys are assigned to specific z/OS components or major subsystems:
  - Key 1 is used by the Scheduler (JES2 or JES3).
  - Key 5 is used by data management.
  - Key 6 is used by the Communications Server.
  - Key 7 is used by IMS.
- Key 8 storage is the key that most application programs use. Although it might seem that using the same key for storage creates integrity problems for one program accessing the memory of another program, this problem does not normally occur because z/OS protects one address space from accessing the private memory of other address spaces. However, common storage that is in Key 8 can be altered (stored into) by most unprivileged user programs.
- If storage is set to Key 9, then programs in any key can access the storage for both Fetch and Store operations. This facility is used in some major software subsystem such as CICS. The facility is an option in z/Architecture terms, but in practice z/OS always makes the function available.
- Keys 10 through 15 are used for programs which need to run REAL, which means they run without the overhead of page movement. Programs with this requirement are rare.
- Key-controlled protection is one of four types of memory protection available within z/Architecture. In order for a memory access to be granted, all four methods must allow the access of the type requested (fetch or store).

For additional information on hardware memory protection facilities, refer to the *z/Architecture Principles of Operation* manual available in the z/OS documentation library (http://www-03.ibm.com/systems/z/os/zos/bkserv/).

KEY

Contains the storage protection key of a memory area. A key of 8 to 15 characters is cause for concern because any user might be able to change the area.

LENGTH

The length of a storage area. This value is a decimal number of up to 11 digits.

START

The start address of a storage area. This value is either an eight-character (four-byte) hexadecimal number or two eight-character hexadecimal numbers separated by an underscore for eight-byte addresses (possibly) situated above the 4 GB threshold. The difference between START and START64 is that START shows if the address has a high-order fullword in the operating system or not. In addition, the START field does not support address sorting. If sorting is required, use the START64 field.

START64

The start address of a storage area as a 64-bit number. This value is formatted as two eight-character hexadecimal numbers separated by an underscore for eight-byte addresses (possibly) situated above the 4 GB threshold. Use this field to sort by address.

SUBPOOL

This field contains the subpool number of a memory area. It is missing for storage areas located above the bar.

SYSTEM

The name of the system. For MVS systems, this value is equal to the SMF system id. This field has a length of 8 characters for compatibility with other NEWLIST types.

TYPE

A string indicating the virtual storage area type. Table 338 documents the available TYPE values and their descriptions. Areas starting with an E reside above the 16 MB virtual storage threshold. Areas that start with an X reside above the 4 GB virtual storage threshold.

Table 338. Virtual storage area type values and descriptions

TYPE value	Meaning
CSA	Common Storage Area
ECSA	Extended Common Storage Area
ESQA	Extended System Queue Area
SQA	System Queue Area
XCOM	Extended Common Storage Area above the bar
XSHR	Extended Shared Storage Area above the bar (previously called XCSA)

DASDVOL: DASD volumes

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The DASDVOL NEWLIST (NEWLIST TYPE=DASDVOL) describes the DASD volumes available on the target systems. Both shared and non-shared information is taken into account, but has the same restrictions as DASD volumes in Security zSecure. That is, SIMULATE SHARED commands might be required. A CKFREEZE file is required

for each of the systems to which the DASD volumes are connected. Systems to which the DASD volume is connected, but for which no CKFREEZE file is read, are not included in the report.

Each entry in this NEWLIST represents one physical DASD volume. Each entry in this NEWLIST can be uniquely identified by the field ORG.

Because this report is not complex-centric at all, the NEWLIST parameter ESM= is not meaningful for this NEWLIST type.

Field descriptions

The DASD NEWLIST provides the following fields for reporting.

ATTR

Text field that is repeated for each of the target systems to which the DASD volume is attached. The value describes the volume attributes for the current system. This field can contain one or more of the following values: IPL for an IPL-volume, MCAT if the volume contains the master-catalog volume for the system, and PAGE if the volume contains a page data set. This field is part of the structured repeat group described with the SYSTEM field.

AUDITCONCERN

Indicates the reason for the audit priority. Do not rely on the exact value of this field in your programs. The contents might change. The value can contain one or more of the following audit concerns separated by commas.

- **Mounted on one system but shared**

  The DASD volume is mounted on only one system but marked shared. This setting causes unnecessary overhead.
- Mounted on more systems but not shared

  The DASD volume is mounted on several systems but not marked shared. No serialization is done for updating the volume, and if two systems try to update simultaneously, an undefined state can result which can cause loss of data.
- **Inconsistently SMS-managed**

  The DASD volume is mounted on several systems, and SMS-managed on some but not all of these systems. This situation can cause problems with APF-libraries on the volume. Also, when data sets are moved to another volume by SMS, jobs might fail and catalog inconsistencies might appear on systems where the volume is not SMS-managed.
- **Inconsistent SMSplex names**

  The DASD volume is mounted and SMS-managed on several systems. However, the SMSplex (sysplex) name, as specified in parmlib member COUPLE*xx*, is not the same for all of these systems.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 339. DASDVOL NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.

Table 339. DASDVOL NEWLIST: Audit priority values and descriptions (continued)

Priority	Meaning
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

BOX_SERIAL

Text field that describes the serial number and device ID for the DASD unit as described by the Common Device Architecture (CDA) commands. The output field has the format `Man-Fa-Serial-Id`, consisting of a Manufacture ID, Factory ID, Serial number, and Device ID.

Table 340 lists some common device IDs from several manufacturers.

Table 340. Manufacturer Device ID values

Id	Manufacturer
IBM	IBM
AM1	Amdahl
HDS	Hitachi
STK	StorageTek

BOX_TYPE

This text field describes the type serial number for the DASD unit as described by the Common Device Architecture (CDA) commands. The output field has the format '**Type-Mod**', consisting of a disk model and disk type, `3390-06` for example.

COMPLEX

The security complex that contains the system. This value can be taken from the ALLOC COMPLEX parameter or default to a system name.

DEVICE

Repeated text field that describes the device number for the DASD volume in three or four hexadecimal characters. This field is part of the structured repeat-group described with the SYSTEM field.

Note: This field is a text field. If you specify selection criteria using the relational operators (`< > ,<=`, or `>=`), the selection is based on *text* values, not on numerical values.

MOUNTED

This flag field is repeated for each of the target systems to which the DASD volume is attached. It describes whether the current system has mounted the DASD volume. This field is part of the structured repeat group described with the SYSTEM field.

If a system has not mounted a volume (`MOUNTED=NO`), most of the fields in the structured repeat group are blank.

ONLINE

Describes the number of systems on which the current volume has been mounted. That is, the number of times the MOUNTED field is set in the structured repeat group described with the SYSTEM field.

ORG

A number identifying the current entry. Currently, numbering starts at 1, and increases by 1 for each physical DASD volume processed.

Note: The function, format, or value for the ORG field might change. For example, the hardware serial number can change. Do not create reports that depend on the output of this field.

SHARED

This flag field is repeated for each of the target systems to which the DASD volume is attached. It describes whether the current system handles the DASD volume as shared with other systems. This field is part of the structured repeat group described with the SYSTEM field.

The SHARED field can cause either of the following audit concerns to be set:

- If volume is marked shared but is only used on one system, a concern is set because the sharing causes an avoidable performance loss.
- If a volume is not marked shared on all systems that share it, a concern is issued because this configuration can lead to unsynchronized updates and cause a loss of data on the volume.

This field reflects the shared attribute as set in the UCB, *not* as set by the SIMULATE SHARED command.

SMS_MANAGED

This flag field is repeated for each of the target systems to which the DASD volume is attached. It describes whether the current system handles the DASD volume as SMS-managed. This field is part of the structured repeat group described with the SYSTEM field.

SYSTEM

This text field is repeated for each of the target systems to which the DASD volume is attached. It describes the system name. This field is the unique index in the structured repeat group also containing the ATTR, DEVICE, MOUNTED, SHARED, SMS_MANAGED, UNIT, and USE fields. If the MOUNTED attribute is not set (MOUNTED=NO) for any of these repeat-group entries, only the SYSTEM and MOUNTED fields in the repeat group entry are set; all others are left blank.

UNIT

This text field is repeated for each of the target systems to which the DASD volume is attached. It describes the unit type name for the volume on the current system. This field is part of the structured repeat group described with the SYSTEM field.

USE

This text field is repeated for each of the target systems to which the DASD volume is attached. It describes the Mount and Use attributes for the volume on the current system, which determines the type of data set that can be placed on a volume. This field is part of the structured repeat group described with the SYSTEM field. Table 341 on page 1016 lists the values of the USE field.

Table 341. Values for USE field

USE value	Meaning
PRIVATE	The volume is only used for allocation requests specifically using this volume.
PUBLIC	The volume is used for scratch data sets, and for allocation requests specifically using this volume.
STORAGE	The volume is used primarily for non-temporary data sets. It can also be used for scratch data sets and allocation requests specifically using this volume.

Note: The mount use attribute is ignored if the volume is SMS-managed.

VOLSER, VOLUME

The volume serial of the DASD volume.

DB2_REGION: DB2 subsystems

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•		•	•	•	•	•

This section describes the fields for the DB2_REGION NEWLIST. This NEWLIST type lists one entry per active DB2 subsystem for each system for which data is available in allocated CKFREEZE data sets. An entry is uniquely identified by the fields COMPLEX, SYSTEM, and DB2ID.

Field descriptions

The `DB2_REGION NEWLIST` provides the following fields for reporting.

ASID

This field contains the address space ID associated with the DB2 region. The address space ID is a 2-byte hexadecimal number.

AUDITCONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field as a programming interface. The AUDITCONCERN field can contain one or more concerns separated by commas.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 342. DB2_REGION NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

CHAROPT

This single character field shows the suffix of the resource classes used by the DB2 RACF security module. Its value is ignored for DB2 subsystems that use classification option (CLASSOPT) 2 for multi-subsystems and for DB2 subsystems that use the default value DSN for the class name root (CLASSNMT).

CLASS_BUFFER_POOL

This field shows the resource class used by the DB2 RACF security module for verification of buffer pool privileges.

CLASS_COLLECTION

This field shows the resource class used by the DB2 RACF security module for verification of collection privileges.

CLASS_DATABASE

This field shows the resource class used by the DB2 RACF security module for verification of database privileges.

CLASS_JAR

This field shows the resource class used by the DB2 RACF security module for verification of Java archive privileges.

CLASS_PACKAGE

This field shows the resource class used by the DB2 RACF security module for verification of package privileges.

CLASS_PLAN

This field shows the resource class used by the DB2 RACF security module for verification of plan privileges.

CLASS_SCHEMA

This field shows the resource class used by the DB2 RACF security module for verification of schema privileges.

CLASS_SEQUENCES

This field shows the resource class used by the DB2 RACF security module for verification of sequences.

CLASS_STOREDPROC

This field shows the resource class used by the DB2 RACF security module for verification of stored procedure privileges.

CLASS_STORGRP

This field shows the resource class used by the DB2 RACF security module for verification of storage group privileges.

CLASS_SYSTEM

This field shows the resource class used by the DB2 RACF security module for verification of system privileges.

CLASS_TABLE_INDEX_VIEW

This field shows the resource class used by the DB2 RACF security module for verification of table, index and view privileges.

CLASS_TABLESPACE

This field shows the resource class used by the DB2 RACF security module for verification of tablespace privileges.

CLASS_USER_FUNCTION

This field shows the resource class used by the DB2 RACF security module for verification of user function privileges.

CLASS_USER_TYPE

This field shows the resource class used by the DB2 RACF security module for verification of user type privileges.

CLASSNMT

This four-character field shows the class name root of the resource classes used by the DB2 RACF security module. The class name root is the middle part of the resource class name, between the prefix and suffix. Its value is ignored for DB2 subsystems that use classification option (CLASSOPT) 1 for single subsystems.

CLASSOPT

This single-digit number field shows the classification option used by the DB2 RACF security module. Possible values are 1 for use of the resource classes by a single DB2 subsystem only, or 2 for shared use of the same resource classes by multiple DB2 subsystems.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

DB2ID

This field shows the DB2 subsystem identification. Maximum length: 4 characters.

GROUP_NAME

This field shows the DB2 group attachment name if the DB2 subsystem is part of a data sharing group. If the DB2 subsystem is not part of a data sharing group, the field is missing (not applicable).

JOBID

This field contains the JES job ID of the DB2 subsystem. Maximum length: 8 characters.

JOBNAME

This field contains the JES job name of the DB2 subsystem. Maximum length: 8 characters.

LU_NAME

This field contains the VTAM LU-name by which this DB2 subsystem is known. It is also used as the VTAM APPL name. The maximum length is 8 characters.

PC_LX

This 4-byte hexadecimal field shows the linkage index (LX) and program call (PC) number used to connect to the DB2 subsystem.

REGION_USERID

This field contains the userid associated with the DB2 subsystem. Maximum length: 8 characters.

SITE_NAME

This field contains the name by which other systems in the network can recognize the DB2 subsystem. In DB2, this field is also known as the location name. The maximum length is 16 characters.

STEPNAME

This field contains the step name associated with the DB2 region. Maximum length: 8 characters.

SUBSYS_CHAR

This field specifies the console command character that is used to enter commands from a console. Length: 1 character.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. The field length is 8 characters for compatibility with other NEWLIST types. Maximum length: 8 characters.

DEFTYPE: user-defined data source

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•	•		•	•	•	•

Use the `NEWLIST TYPE=`*`deftype`* to specify user-defined files to provide maximum flexibility in reporting on any database or logfile necessary. You can use this `NEWLIST` for defining extra log types or adding lookup data to reports. You must define the *deftype* through a `DEFTYPE` statement. It has few predefined fields.

Field descriptions

The `DEFTYPE NEWLIST` provides the following fields for reporting.

COMPLEX

The security complex to which the file has been assigned. This value comes from the ALLOC COMPLEX parameter.

DDNAME

The DDNAME of the file containing the record.

RECNO

The record number of the current record within its input file (not overall). The RECNO field applies to the number of complete **logical** records within a single input file, counting the first record as 1.

Note: For SELECT/EXCLUDE processing, only the =. <>, and ¬= relational operators can be used.

RECORD

The RECORD field contains a single full record. This field is designed to be used with the DEFINE command in combination with field-value manipulation functions. See "DEFINE" on page 750 and "Field value manipulation" on page 760.

Note: This field has format ASIS by default, which has been built specifically to keep trailing spaces intact. This format is also inherited by fields defined with RECORD as base. If trailing spaces need to be trimmed, use the overriding format CHAR can be used.

RECORDLENGTH, RECORD_LENGTH

This field describes the length of the DEFTYPE record in bytes, excluding the RDW. The given length is the one of the **logical** record.

DSN: Data Set Names (non-VSAM)

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The DSN NEWLIST (NEWLIST TYPE=DSN) describes the data set names on the system, annotated with protection information. This NEWLIST requires input source files that include one or more CKFREEZE files with data set information. Each record in this NEWLIST represents a data set name, including references without an actual data set name. A record is uniquely identified by the fields SYSTEM, COMPLEX, DSN_TYPE, DSNAME, VOLUME, CATALOG, CATALOG_VOLUME, REAL_DSN and REAL_VOLUME. For information about these fields, see "Field descriptions."

Note: The present version only reports non-VSAM data sets (DSN_TYPE=' nvsam'). It does not report non-VSAM aliases. It does not relate migrated data set names to REAL_DSN and REAL_VOLUME. It does not support GDGs.

Field descriptions

The DSN NEWLIST provides the following fields for reporting.

ALIAS_RELATE

Contains the catalog name related to the CATALOG_ALIAS used for this data set. That is, the catalog the data set is found in using a standard search, if any. For a symbolic relation, this field shows the symbolic name. See ALIAS_RELATE_EFFECTIVE, VIA_SYMBOLIC_RELATE.

ALIAS_RELATE_EFFECTIVE

Contains the catalog name related to the CATALOG_ALIAS used for this data set. That is, the catalog the data set is found in using a standard search, if any. For a symbolic relation, this field shows the resolved name. See ALIAS_RELATE, VIA_SYMBOLIC_RELATE.

BOX_SERIAL

Describes the volume serial number and device ID for the DASD unit where the data set is stored. This field can be used to disambiguate between DASD volumes with the same VOLSER. See also "BOX_SERIAL field for DASDVOL report" on page 1014.

CATALOG

Contains the name of the catalog the data set name is in.

CATALOG_ALIAS

Contains the catalog alias that is used for this data set name in a standard search, if any alias is used. See ALIAS_RELATE, ALIAS_RELATE_EFFECTIVE, VIA_SYMBOLIC_RELATE.

CATALOG_VOLUME

This field contains the volume where the catalog resides that contains an entry for this data set.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

Contains the name of the security complex. This value can be taken from the COMPLEX= keyword on an explicit ALLOC statement or it can default to a system name.

DSN, DSNAME

Contains the data set name. This value might only be a reference, a catalog entry for example. See REAL_DSN.

DSN_TYPE

Contains the data set type. Currently always 'nvsam' for non-VSAM.

IN_CONNECTED_CATALOG

Flag field that indicates if the data set is cataloged in a user catalog connected to the master catalog.

IN_DIRECTED_CATALOG

Flag field that indicates if the data set is cataloged in a catalog that is not used in a standard search.

IN_MASTER_CATALOG, IN_MCAT

Flag field that indicates if the data set is cataloged in the master catalog of this SYSTEM.

IN_VTOC

Flag field that indicates if the data set occurs in the *Volume Table Of Contents* for VOLUME.

IN_VVDS

Flag field that indicates if the data set occurs in the *VSAM Volume Data Set* of VOLUME. A non-VSAM data set occurs in the VVDS if it is SMS-managed.

IS_MIGRATED

Flag field that indicates if the data set name references a migrated data set.

IS_MOUNTED

Flag field that indicates if VOLUME is mounted.

PROFILE

The RACF profile protecting this data set (RACF systems only). See RESOURCE.

QUAL

Contains the first qualifier of the resource name checked for this data set as translated by ICHNCV00 and ICHCNX00. See RESOURCE.

QUAL_IS_DATASET_PROFILE

Flag field that indicates if a profile exists in the RACF database of the form *qual.*** or *qual.*.***, where *qual* is the first qualifier of the resource name checked for this data set.

QUAL_IS_GROUP

Flag field that indicates if the first qualifier of the resource name checked for this data set matches a group in the security database.

QUAL_IS_USER

Flag field that indicates if the first qualifier of the resource name checked for this data set matches a user ID in the security database.

REAL_DSN, REAL_DSNAME

Contains the real data set name. This value is equal to the DSNAME if the data set occurs in the VTOC. Otherwise, the value is missing.

REAL_VOLUME

Contains the real volume for the data set. The value is the same as the VOLUME if the data set occurs in the VTOC. Otherwise, the value is missing.

RESOURCE

Contains the resource name checked for this data set as translated by ICHNCV00 and ICHCNX00.

SENSITIVITY

Contains the data set sensitivity type for sensitive data sets. See the SENSITIVITY field description in "SENSITIVITY" on page 1258 for the sensitive data sets automatically recognized.

SYSTEM

Contains the name of the (viewpoint) system. For MVS systems, this value is the SMF system ID. The default field length is the field is 8 characters for compatibility with other NEWLISTs.

UNITTYPE

This field contains the device type for the data set volume.

VIA_SYMBOLIC_RELATE

Flag field that indicates the CATALOG_ALIAS used for this data set in a standard search (if any) has a symbolic relation. See ALIAS_RELATE, ALIAS_RELATE_EFFECTIVE.

VOLUME, VOLSER, VOL

Contains the data set volume. This value might only be a reference, a catalog entry for example. See REAL_VOLUME.

DSNT: RACF Data Set Name Table

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•		

The DSNT NEWLIST (NEWLIST TYPE=DSNT provides information about the in-storage Data Set Name Table per system. This table is built as the result of the contents of the ICHRDSNT module at IPL, subsequent RVARY commands, and possibly operator replies. Unless otherwise stated, all fields can be used for SELECT or EXCLUDE processing as well as in the following output commands: LIST, SORTLIST, DISPLAY, and SUMMARY. The DSNT NEWLIST generates one entry per in-storage Data Set Name Table entry per system. A unique key for this NEWLIST is the SYSTEM ORDER field.

Field descriptions

The DSNT NEWLIST provides the following fields for reporting.

ACTIVE

Active flag, indicating whether this data set is currently active.

ATTR

A string listing the RACF data set attributes, with a text representation of all flag fields that are set. The following table shows the flags used to make up this string.

Flag	String entry	Meaning
ACTIVE	Act	Active data set
CMS	CMS	Data set in CMS minidisk format
DATABUF	Databuf	Data block buffering active
	DataShare	Data sharing mode active, all other members in IRRXCF00 in data sharing mode or read-only.
	DataShareR/O	Read-only mode active, all other members in IRRXCF00 in data sharing mode or read-only.
	DataShareTrn	Transition mode, will be in data sharing or read-only mode after connect service completes.
MSTR	Mstr	Master data set
PRIM	Prim	Primary data set
RDS	RDS	Restructured data set
SHR	ShrDASD	Master data set is on shared DASD. ICB is read often.
STAT	Stat	Statistics are updated by RACINIT

BUFNO

The number of resident data blocks in (E)CSA. This value is a number in the range of 0 - 255. Higher numbers indicate more storage and potentially better performance. If the installation has not provided an ICHRDSNT module, RACF

uses 10 resident data blocks when sysplex communication has not been enabled. If sysplex communication has been enabled, RACF enforces a minimum value of 50 resident data blocks.

CMS

This flag indicates whether the data set is in CMS minidisk format.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. This value is taken from the `ALLOC COMPLEX` parameter or default to a system name.

DB, SEQNO

Database sequence number. This number is referred to by the Range Table, which can be displayed with the `NEWLIST TYPE=RRNG`.

DSN, DATASET

Data set name for this database sequence number. This value can be empty if no data set has been defined for a specific backup or sequence number, or if a data set has been made inactive.

MSTR, MASTER

Master data set flag. If this flag is set, this data set is the master data set. The master data set is the data set from which the system-wide options are read from the first block in the data set (the Index Control Block or ICB) during IPL.

ORDER, ORG

The original order (entry number) of this data set entry in the Data Set Name Table. The first entry in the table has ORDER=1.

PRIM

Primary data set flag. If this flag is set, this data set is a primary data set (as opposed to a backup data set). More I/O is performed on a primary data set.

The first primary data set is considered to be the master data set, unless it is set to an asterisk (*) in load module ICHRDSNT. In this case, the operator is prompted during initialization to supply the data set name. The PRIM field reflects the actual data set name in use, whether supplied at IPL, or changed by an RVARY command.

RECTRK

The number of physical blocks per DASD track.

SEQNO

An alias of `DB`. See DB, SEQNO.

SHR, SHARED

Shared flag indicating whether this database is shared with other (MVS or VM) systems. This value is obtained by RACF from the characteristics of the DASD device on which the RACF database is located. If RACF is not activated in sysplex data-sharing mode, the `SHR=YES` results in RACF frequently reading the

Inventory Control Block (ICB) to check for updates made by another system. If RACF is activated in sysplex data-sharing mode, the SHR value is irrelevant.

STAT, STATS, INITSTATS

Indicates if statistical updates to RACF profiles are reflected in the RACF backup data base. Statistics in RACF profiles exist as RACINIT statistics–also known as LOGON statistics–as well as discrete PROFILE access statistics. Maintenance of these statistics is controlled by SETROPTS settings in combination with the installation provided ICHRDSNT module. The STAT flag only reflects the ICHRDSNT-related setting. The SETROPTS settings are controlled by the INITSTATS and the STATISTICS(*classname*) settings.

If RACINIT statistics are to be maintained, RACF sometimes ignores the STAT flag to reliably support the revoke of inactive users.

SYSTEM

The name of the system. For MVS systems, this value equals the SMF system ID. The field length is 8 characters for compatibility with VM systems.

VOLUME, VOLSER, VOL

DASD volume serial for this data set.

DYNEXIT: System Exits

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The DYNEXIT NEWLIST (NEWLIST TYPE=DYNEXIT) provides information about the dynamic exit routines. For each system, this NEWLIST generates one entry per defined dynamic exit. In general, an entry is uniquely identified by the fields SYSTEM and EXITNAME.

Field descriptions

The DYNEXIT NEWLIST provides the following fields for reporting.

ABENDCONSEC

The ABENDNUM and ABENDCONSEC fields indicate how the system handles the abnormal ending of an exit routine. The ABENDCONSEC field indicates whether abnormal endings of an exit routine are counted consecutively (ABENDCONSEC=YES) or cumulatively (ABENDCONSEC=NO).

For more details, see the z/OS internet library. Find the z/OS information center for your z/OS version and search for the ABENDCONSEC field.

ABENDNUM

The ABENDNUM and ABENDCONSEC fields indicate how the system handles the abnormal ending of an exit routine. The ABENDNUM field specifies the number of abnormal endings that can occur before the exit routine becomes inactive. An inactive exit routine is associated with an exit but is not called.

For more details, see the z/OS internet library. Find the z/OS information center for your z/OS version and search for the ABENDNUM field.

AUDITCONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field as a programming interface. The AUDITCONCERN field can contain one or more concerns separated by commas.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 343. DYNEXIT NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

ACTIVE#

Contains the number of active exit routines for the exit point.

AMODE

Contains the required addressing mode for exit routines. Possible values are *24*, *31*, or *Def*. The value *Def* indicates that the exit routine takes control in the AMODE that was defined for the load module for the exit routine at the time it was created.

ANYKEY

Flag field that indicates if an exit routine can be called in any key. The field requires that the exit routines are reentrant, and only applies to exit routines that are called in fast path mode.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

Specifies the security complex that contains the system. This value can come from the `ALLOC COMPLEX` parameter or a default determined by the application.

DESC, DESCRIPTION

A string of up to 45 characters that explains the exit function. The description is taken from an internal knowledge base.

EXECKEY

Shows the storage key and execution key that is used when the exit module is called. This field is only present for modules that are defined for a dynamic exit point. These keys are specified by the application when the dynamic exit point is defined. The field only applies to non-reentrant modules and to modules called in fast path mode.

EXITNAME

Describes the full name of the dynamic exit as specified by the `EXITNAME` parameter in the `PROGxx` member in `PARMLIB`.

EXPLICIT
Flag field that indicates if the exit module has been defined. This field is only present for modules that are defined for a dynamic exit point.

YES indicates that the exit module has been defined. This value corresponds to the value E for the defined status as reported by the D PROG operator command.

NO indicates that the exit module has not been defined. This corresponds to the value I for the defined status as reported by the D PROG,EXIT operator command.

FASTPATH
Flag field that indicates if the exit routine can be called in fast path mode. When the exit routine is called in this mode, it provides reduced recovery, and the exit routine runs in the state and key of the caller. Fast path must also be explicitly requested by the exit caller to be used.

INACTIVE#
Contains the number of added, but inactive exit routines for the exit point.

RENT_REQ
Specifies whether exit routines to be added to the exit are required to be reentrant.

SINGLEMODULE
Flag field that indicates that only a single module can be associated with the exit point at a time.

SYSTEM
Returns the name of the system. For MVS systems, this value is equal to the SMF system ID. The field is eight characters long.

EXIT: System Exits

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The EXIT NEWLIST (NEWLIST TYPE=EXIT) provides information about system exits. For each system, this NEWLIST generates one entry per exit or table. However, some exits are taken from a directed load, such as STEPLIB. When more than one data set with the exit is found, the exit is reported multiple times. For implicit dynamic exits, the associated modules might not be included in the EXIT NEWLIST report. The program does not attempt to locate these modules, and they are not listed as exit routines.

In general, a unique key for an entry in the EXIT NEWLIST is SYSTEM PROGRAM JOBNAME ADDRESS. For dynamic exits, the unique key also includes the EXITNAME field.

Field descriptions

The Exit NEWLIST provides the following fields for reporting.

ACTIVE
Flag field that indicates if a module is active. This field is only present for modules that are defined for a dynamic exit point.

YES indicates that the module is active.

NO indicates that the module is defined as INACTIVE or that it has become inactive because of an ABEND.

ACTIVE_EFFECTIVE
Flag field (YES or NO) that can be used to determine if a module is called as a dynamic exit routine. This field is only present for modules that are defined for a dynamic exit point. It is the logical combination of the ACTIVE and EXPLICIT fields.

ADDRESS

This field contains the address of the exit or table. For exits, this is the *entry point* of the exit, for example the address used by MVS to branch to this exit routine. For tables, this is the start address of the table.

AMODE

This field contains the addressing mode of the exit or table. This will be **24**, **31**, or **64**.

ANYKEY
Flag field (YES or NO) that indicates if an exit routine can be called in any key. This field is only present for modules that are defined for a dynamic exit point. This field only applies to exit routines that are reentrant.

APPL

Indicates the application or subsystem owning the exit or table. The following table shows the exit types supported by the current version, and the resulting values of the APPL field:

Table 344. Exit type and associated APPL field value

Application/Subsystem	APPL value
ACF2	ACF2
CA-1	CA1
dynamic exit facility	dynamic
HSM	HSM
I/O appendage	IOAPP
JES2	JES2
MPF	MPF
RACF	RACF
SMF	SMF
TSO	TSO
WTO	WTO

AT

This field contains a short description of the exit program name, module name, and offset, in the format described in the following table. The format is derived from the exit's entry point.

Table 345. AT description format

AT format	Minor/Major EP	Offset zero
Module	Major	Yes
Module+offset	Major	No

Table 345. AT description format (continued)

AT format	Minor/Major EP	Offset zero
Program in Module	Minor	Yes
Program+offset in Module	Minor	No

AUDITCONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field. Audit concerns are described in the following list. The AUDITCONCERN field can contain one or more concerns separated by commas.

- Exit in writable common storage

  The exit code resides in writable common storage; any user can alter the exit.
- String scan hit

  The SCAN_STRING field registered a hit: a user-defined string was found in the exit code.
- SVC scan hit

  The SCAN_SVC field registered a hit: a user-defined SVC call was found in the exit code.
- Instruction scan hit

  The SCAN_INSTR field registered a hit: one or more specific instructions scanned for were found in the exit code.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 346. EXIT NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

The security complex that contains the system. The complex name can come from the ALLOC COMPLEX parameter or default to a system name.

CONTENT, CONTENTS

This field contains up to the first 256 bytes of the contents of the exit or table, which usually include the eye catcher. The default output length of this string is 59 characters (containing the first 59 bytes of the exit). In the default output

format, the readable text from the contents is shown; the non-printable parts of the contents have been replaced by one or two dots.

DESC, DESCRIPTION

A string of up to 45 characters explaining the function of the exit or table. The description is taken from an internal knowledge base.

EXECKEY

This field shows the storage and execution key that is used when an exit module is called. This field is only present for modules that are defined for a dynamic exit point. The key values are specified by the application when the dynamic exit point is defined. The field only applies to non-reentrant modules and to modules called in fast path mode.

EXITNAME

If the current exit is dynamic, this field describes the full name of the dynamic exit, as specified by the EXITNAME parameter on the PROGxx member of SYS1.PARMLIB. If the exit is not a dynamic exit, this field is blank.

EXPLICIT

Flag field that indicates if the module has been added to a defined exit point. This field is only present for modules that are defined for a dynamic exit point.

YES indicates that the module has been added to a defined exit point. This value corresponds to the value E for the defined status as reported by the D PROG operator command.

NO indicates that the module has been added, but the exit point has not been defined. This corresponds to the value I for the defined status as reported by the D PROG,EXIT operator command.

FILTER_JOBNAME

Shows the `JOB` filter pattern used to control if this module is started. This field is only present for modules that are defined for a dynamic exit point. This field is empty if the `FILTER_TYPE` is not *Jobname*.

FILTER_STOKEN

Shows the Address Space `STOKEN` filter used to control if this module is started. This field is only present for modules that are defined for a dynamic exit point. The field is empty if the `FILTER_TYPE` is not *SToken*.

FILTER_TYPE

Shows the type of filter defined for the exit module. This field is only present for modules that are defined for a dynamic exit point. Filtering can be done by `jobname` or by active primary address space (`stoken`). Jobname filtering can be specified either using the API interface or the `SETPROG` operator command. `STOKEN` filtering can only be specified using the API interface. This field can return the following values for the FILTER_TYPE: *Jobname*, *SToken*, or blank if filtering is not active.

JOBNAME

If the exit resides in PVT or EPVT, this field contains the jobname of the address space in which the exit is located. If the exit lies in common storage (and is available to all address spaces), this field is left blank.

KEY

This field contains the storage protection key of the exit or table, if the exit or table is in CSA, ECSA, SQA, or ESQA.

A key of 8 is a serious cause for concern; any user might be able to change the exit. A key of 9 to 15 is a minor cause for concern; only users running in that key will be able to change the exit, while keys 9 to 15 can normally only be used by controlled applications, when running programs from APF libraries. An exception goes for ADDRSPC=REAL, see 1451.

LENGTH

This field contains the length of the program/module the exit or table is part of, if the residency is in the LPA (EFLPA, EMLPA, EPLPA, FLPA, MLPA, PLPA). If CKFREEZE contains sufficient information, it might also be filled in if the residency is a server address space private area (PVT, EPVT). The length is approximated as the length up to the end of the module, or the length up to the next entry point.

MODULE

This field contains the major entry point name of the module in which the table or exit is located, if the residency is in the LPA (EFLPA, EMLPA, EPLPA, FLPA, MLPA, PLPA). If CKFREEZE contains sufficient information, it might also be filled in if the residency is a server address space private area (PVT, EPVT)

OFFSET

This field contains the offset between the program's entry point and the exit or table address, if the residency is in the LPA (EFLPA, EMLPA, EPLPA, FLPA, MLPA, PLPA). If CKFREEZE contains sufficient information, it might also be filled in if the residency is a server address space private area (PVT, EPVT). The offset is calculated from the previous entry point, and is zero if the address is located at a minor or major entry point.

PARAM

Shows an optional input parameter that is passed to the exit routine. This field is only present for modules that are defined for a dynamic exit point. The value returned corresponds to the value shown when using the `DIAG` option of the `D PROG,EXIT` operator command. By default, the `PARAM` field is shown as 16 hex digits, while the `D PROG,EXIT` operator command tries to show the field as printable characters. The PARAM field is only present when using a `CKFREEZE` file created by CKFCOLL V 1.12 or later, running on a z/OS system, V 1.12 or later.

POSITION

Shows the sequence number in which the module is called for the exit point. This field is only present for modules that are defined for a dynamic exit point. The POSITION field is only valid when using a `CKFREEZE` file created by CKFCOLL V 1.12 or later. For `CKFREEZE` files created using a earlier release level of CKFCOLL, the value zero is suppressed.

PROGRAM

Depending on the exit type, this field contains one of the following types of data:

1. The documented name of the exit. This does not need to correspond to the actual module name (because this reflects an exit address in a control block). This happens for ACF2, JES3, and RACF exits. For in-storage tables that represent the combination of two or more modules, a name is constructed with a lowercase character in the name, for example, ICHRRCDx is the name that is constructed for load modules ICHRRCDE and ICHRRCDX.
2. A documented exit name that is also the actual load module name. This happens e.g. for some DFSMS, MVS, and VTAM exits.

3. The name according to some descriptor control block (for example, for JES2 , CA-1, TSO, and dynamic exits), where the name does not need to correspond to the actual module name, but often does if the exit has not been front-ended.

For the actual load module name associated with the exit address used by z/OS, see the field AT.

RESULT

This field is always blank for tables; for exits, it contains a string containing the result of a disassembly of the exit. Set to 'RC=**n**' if the exit has a fixed return code of 0, 4 or 8; empty otherwise. For the password encryption exit ICHDEX01 or ICHDEX11, the string is set to 'RC=**x: comment**', where 'comment' describes the effect of the return code. Possible values of RESULT for ICHDEX01 are documented in the following table.

Table 347. RESULT values for password encryption exit ICHDEX01

Return code	RESULT value
0	RC=0: Installation-defined encryption
4	RC=4: Force masking, no DES encryption
8	RC=8: Force DES encryption, no masking

SCAN_INSTR

This field describes the result of an *instruction scan* performed on the full exit code. It is only available if the CKFREEZE file used was produced with the SCAN=YES parameter. The instruction scan is performed on the full length of the exit (not just on the eye catcher), and checks for suspicious instructions in the code.

Note: You should use the contents of this field as a warning, not as a certainty. The instruction scan might cause false alarms, and can also be fooled to miss certain instructions. You should always review the source code of suspicious modules.

When used for SELECT/EXCLUDE processing, you can use SELECT SCAN_INSTR or SELECT SCAN_INSTR=ANY to select routines in which *any* specified instruction was found; use SELECT SCAN_INSTR=NONE to select routines in which no specified instructions were found. In addition, you can select routines containing any of the specific instructions listed in the following table, for example, SELECT SCAN_INSTR=(FAKEAPF,FAKESPEC).

Because many suspicious instructions can be found within a single module, the default output of this field is in a condensed format; full output split into several lines can be requested using the EXPLODE output modifier and an overriding length of 9, for example SCAN_INSTR(EXPLODE,9). The following table lists the SCAN_INSTR values that can be used for SELECT/EXCLUDE processing; the condensed output; the exploded output; and the meaning.

Table 348. SCAN_INSTR values available for SELECT/EXCLUDE processing

Select/Exclude	Condensed	Exploded	Meaning
BYPASS BYPASSSAF	.B.....	BypassSAF	Request DFP (DFSMS) to bypass SAF calls
FAKEAPF	A.....	FakeAPF	Fake APF/AC(1)-authorization
FAKEOPER	.....O.	FakeOper	Set operations authority

Table 348. SCAN_INSTR values available for SELECT/EXCLUDE processing (continued)

Select/Exclude	Condensed	Exploded	Meaning
FAKEPRIV	......P	FakePriv	Set privileged/trusted authority
FAKESPEC	....S..	FakeSpec	Set special authority
KEYZERORB	...0...	KeyzeroRB	For an SVC: modify caller's RB to key-zero
MODESUPRB	..M....	ModeSupRB	For an SVC: modify caller's RB to supervisor mode

Note: The values printed by the SCAN_INSTR field are subject to change. Do not write applications that are dependent on the output of this field.

SCAN_STRING

This field describes the result of a *string scan* performed on the full exit code. It is only available if the CKFREEZE file used was produced with the SCAN=YES parameter and SCANSTR arguments set. The string scan is performed on the full length of the exit (not just on the eye catcher), and checks for user-specified strings in the code.

The value of this field is set to **Yes** if a matching string was encountered in the code; **No** if no string was found; the field is left blank if no string scan was performed.

SCAN_SVC

This repeated field describes the result of an SVC *scan* performed on the full exit code. It is only available if the CKFREEZE file used was produced with the SCAN=YES parameter and SCANSVC list of SVC numbers set. The SVC scan is performed on the full length of the exit (not just on the eye catcher), and checks for user-specified SVC calls in the code.

Note:

You should use the contents of this field as a warning, not as a certainty. The SVC scan might cause false alarms, and can also be fooled to miss certain SVC calls. You should always review the source code of suspicious modules.

The value of this field has the format *num*: *description* if the SVC scanned for was one of the first seven specified in zSecure Collect. If any of the other SVCs scanned for was encountered, this field has the value *Other*.

SUBPOOL

This field contains the storage area subpool of the exit or table, if the residency is in CSA, ECSA, SQA, or ESQA.

SUBSYS, SUBSYSTEM

This field contains the name of the subsystem owning the exit or table. In the current version of Security zSecure, this field will only be set for JES2 exits (APPL=JES2), and be left blank otherwise. The SUBSYS field describes the actual JES2 name. For more information on the subsystem, use the NEWLIST TYPE=SUBSYS described in section 'SUBSYS MVS Subsystems'.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. This field length is 8 characters to cater to VM systems.

WHERE

A string indicating the virtual storage area where the exit or table resides. Possible WHERE values and their meaning are documented in the following table; areas starting with an E reside above the 16 MB line in virtual storage.

Table 349. WHERE values and descriptions

WHERE value	Meaning
CSA	Common Storage Area
ECSA	Extended Common Storage Area
EFLPA	Extended Fixed Link Pack Area
EMLPA	Extended Modified Link Pack Area
ENUC RO	Read-only Extended Nucleus Area
ENUC RW	Writable Extended Nucleus Area
EPLPA	Extended Pageable Link Pack Area
EPVT	Extended Private Area
ESQA	Extended System Queue Area
FLPA	Fixed Link Pack Area
MLPA	Modified Link Pack Area
NUC RO	Read-only Nucleus Area
NUC RW	Writable Nucleus Area
PLPA	Pageable Link Pack Area
PSA	Prefix Storage Area
PVT	Private Area
SQA	System Queue Area

FIELD: Field Properties per NEWLIST type

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

The `FIELD NEWLIST` (`NEWLIST TYPE=FIELD`) lists fields for all Security zSecure report or `NEWLIST` types with most of their properties like default output length, format, headers, and so on. For some NEWLIST types, additional fields are available but not present in `TYPE=FIELD`. In that case, a separate `NEWLIST` type is available to list the additional fields defined in a security database. For RACF profiles (`NEWLISTYPE=RACF`) use `TYPE=TEMPLATE` to see the fields defined through RACF database templates. The fields listed in the FIELD NEWLIST are similar to these other `NEWLIST`s, but `TYPE=FIELD` lists pseudo-fields that are not available directly in the security database. In the ISPF user interface, the result can be displayed through the FIELD primary command, which imbeds the CARLa script `C2RDFLD`. This script also provides sample CARLa statements for using the `FIELD NEWLIST`.

Field descriptions

You can use the following fields to select and create audit reports for System settings.

ADVERTIZE

Flag indicating whether the field should be advertised. This is set to NO for fields where a better alternative is available, and for fields that are not available for either direct selection or direct output. It is up to the CARLa writer to decide whether to include those or not. The FIELD primary command only shows fields that should be advertised.

BASE

This indicates whether the field value is derived from another field value (but not exactly the same, like it would be for an alias name - alias names are not available in TYPE=FIELD). Maximum length is 24 characters, default length is 8 characters, If present, the field inherits some properties from the base field. For example, which segment should be read to be able to do a lookup, and which resource name should be used for FIELD scoping checks.

CASESENSITIVE

Flag indicating whether user input on a modifiable field is case-sensitive. It is off if the field is not modifiable.

COMPARE_USAGE

This flag field determines whether the specified field can be used in a comparison process as specified in a COMPAREOPT COMPARE statement.

COMPARE_USAGE_BY

This flag field indicates whether the specified field is included in the default BY specification which specifies the key of the record to be used in a comparison process. For more information, see the COMPAREOPT statement.

COMPARE_USAGE_COMPARE

This flag field indicates whether the specified field is part of the default COMPARE specification. For more informations, see the COMPAREOPT statement.

COMPLIANCE_IMPROVEMENT

Indicates whether a change in the value of a field resulted in increased or decreased security compliance. Table 350 lists the possible field values. This field is included in the COMPARE_CHANGES field that reports the changes detected during a comparison process. Use input and output formats to determine whether the compliance value information is included in the comparison data reported by COMPARE_CHANGES. For more information, see “COMPARE processing output formats: Formatting COMPARE_CHANGES results” on page 829.

Table 350. Compliance Improvement - possible field values

Compliance value	Meaning
Increasing	The change detected for the specified field increased the security compliance. In reports and displays, changes that result in increased compliance have a + indicator.
Decreasing	The change detected for the specified field decreased security compliance. In reports and displays, changes that result in decreased compliance have a - indicator.
Missing	The current NEWLIST is not the result of a comparison operation.

DESCRIPTION

Field prefix header. Maximum length is 29 characters. You get this by using the PREFIX modifier on a field on a LIST, SORTLIST, DISPLAY, SUMMARY, DSUMMARY, or DEFINE AS statement, or HEADER=PREFIX on a NEWLIST, BUNDLE, PRINT, or OPTION statement.

DESCRIPTION_ORIG

This field shows the original (English) default field prefix header (field label). The maximum length is 29 characters.

FIELD

Field (variable) name. Maximum length is 24 characters. This is the built-in field name you can specify on a LIST, SORTLIST, DISPLAY, SUMMARY, DSUMMARY, SELECT, EXCLUDE, or DEFINE AS statement behind a NEWLIST statement with the appropriate type (see field NEWLIST_TYPE).

FIELD_TAG

IBM Security zSecure internal number identifying built-in fields within the NEWLIST type.

FORMAT

Output format name. Maximum length is 16 characters.

HEADER

Default column header when the field is used on SORTLIST, DISPLAY, SUMMARY or DSUMMARY.

HEADER_ORIG

This field shows the original (English) default field column header. The maximum length is 48 characters.

HELP_PANEL

Field-level help panel name. Maximum length is 8 characters. This is the help panel that will be displayed when pressing HELP while the cursor is on the field value or its column header or prefix header in an ISPF display (caused by a DISPLAY or DSUMMARY statement listing the field in FIELD).

HORIZONTAL

Repeating values must be displayed horizontally. See also “HORIZONTAL” on page 805.

LENGTH

Default output length.

LENGTH_ORIG

This is a decimal number that shows the original (English) default field output width. The field length is 6.

LOOKUPONLY

Flag indicating that the field can only be used as a lookup target field (for example, the right side of a lookup operator). This flag is only present for a number of TYPE=RACF fields.

MAXIMUM_LENGTH

Field indicating maximum length on input. If omitted this is taken to be the same as the output length on a display and subject to a general limit on SELECT.

MODIFIABLE

Flag indicating whether field might be modified on the display if an appropriate product is installed and not disabled. In addition, actual modifiability might be restricted by insufficient OS or security system software and database levels.

NEWLIST_ABBREV

A 2-character key for NEWLIST type as used in CKR.ACTION resource names. See also *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

NEWLIST_TAG

IBM Security zSecure internal number identifying the NEWLIST type.

NEWLIST_TYPE

A NEWLIST type. The maximum length is 24 characters. For the list of NEWLIST types see "Overview of NEWLIST types" on page 850. NEWLIST types starting with R_ are an abbreviated form of REPORT_.

REPEATED

Flag indicating whether this field can return more than one value in a single record.

RESTRICT

Field that contains output and scope restrictions. It is a character field with one or more strings. All of those restrictions except 'Sensitive' are only returned if running in restricted mode. It is currently only filled in for NEWLIST_TYPE RACF.

Auditor
In restricted mode, limit display to system-wide auditors and group auditors.

Field
In restricted mode, limit display to people with FIELD authority.

CKGownr
In restricted mode, the field is visible for objects in the CKGRACF scope with READ access. See "Scope profiles" on page 1563 to see how this scope is defined.

Owner
In restricted mode, the field is visible when the object is in the RACF or CKGLIST scope of the user. The RACF scope includes system-special, system-auditor, system-operations, group-special, group-auditor, group-operations, and ownership scope as appropriate for the RACF class.

Read
In restricted mode, the field is visible when the user has READ access or higher on the object.

Repeat
In restricted mode, the individual repeat group entries are subject to individual scope checks.

Sensitive
The field contains sensitive data like passwords or encryption keys that should not be stored outside the security database or printed.

SUBSELECT

This (repeated) field can contain the name of one or more subselect groups (ACL, CONNECTS, or USR). This means the field can only be used in a DEFINE SUBSELECT statement, unless it is also present in TYPE=TEMPLATES.

TRANSLATED

This boolean flag indicates whether the LANGUAGE statement contains a FIELD clause for this field. The field length is 3.

WRAP

Field must be wrapped to the next display line(s) if the output area is not wide enough. See "WRAP" on page 802.

FIELD_OVERRIDE

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

FIELD_OVERRIDE NEWLIST enumerates the output fields encountered in this run that have field-level overrides. The FIELD_OVERRIDE records list original and translation properties for each visible field or output string occurrence on LIST, SORTLIST, DISPLAY, SUMMARY, or DSUMMARY specifications where a length, header, or prefix header property was specified in the CARLa TYPE=FIELD_OVERRIDE.

The default toptitle for this NEWLIST is: NEWLIST FIELD OVERRIDES. The key for a FIELD_OVERRIDE record is NEWLIST_TYPE NEWLIST_NAME SRCEDDN SRCEMEM SRCELINE ORDER FIELD OCCURRENCE.

Field descriptions

The FIELD_OVERRIDE NEWLIST provides the following fields for reporting.

DESCRIPTION

This field shows the original (English) default field prefix header (field label). The maximum length is 29 characters.

DESCRIPTION_ORIG

This field shows the original (English) default field prefix header (field label). The maximum length is 29 characters.

FIELD

This is the field name as it occurs on the LIST family statement, except that for TYPE=RACF alias field names might have been converted to canonical field names. The maximum length is 24 characters.

HEADER

This field shows the final (optionally translated) column header as it is used. It is empty if a prefix header was used. The maximum length is 48 characters.

HEADER_ORIG

This shows the column header as implied by the LIST family command. It is empty if a prefix header was used. The maximum length is 29 characters.

LANGUAGE

A three character abbreviation that identifies the target language for the translated version of the output from this NEWLIST.

LENGTH

This is a decimal number that shows the original (English) default field output width. The field length is 6.

LENGTH_ORIG

This is a decimal number that shows the original (English) output width (the CARLa length override if present). The field length is 6.

NEWLIST_NAME

The NEWLIST_NAME field shows the NAME passed on the NEWLIST statement, optionally suffixed with `.DISPLAY` if the NEWLIST contains a DISPLAY or DSUMMARY statement, as opposed to only a subset LIST, SORTLIST, and SUMMARY. This field has a maximum length of 16.

NEWLIST_TYPE

The NEWLIST type in character format. This field has a maximum length of 24.

OCCURRENCE

This field displays a number 1 for the first occurrence of a field in the CARLa input, and one higher for each subsequent occurrence. The field length is 2.

ORDER

This field displays a number reflecting the order of the fields as encountered in the CARLa input. The field length is 5.

SRCEDDN

Contains the ddname where the field was encountered. The field length is 8.

SRCELINE

Contains the ddname where the field was encountered. The field length is 8.

SRCEMEM

Provides the member name where the field was encountered, if the ddname is not unique). The field length is 8.

VAL

Shows the final string value after translation. The maximum length is 29 characters.

VAL_ORIG

This shows the original string value as it occurred on the CARLa LIST family command. The maximum length is 29 characters.

IMS_PSB: IMS program specification blocks

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
				•	•	•

This section documents the fields for the NEWLIST TYPE=IMS_PSB. This NEWLIST type lists one entry per active IMS program specification block (PSB) for an IMS subsystem in each system. An entry is uniquely identified by the following fields: SYSTEM, COMPLEX, ASID, JOBNAME. and PSBNAME.

Field descriptions

The IMS_PSB NEWLIST provides the following fields for reporting.

ASID

This field contains the address space ID associated with the IMS subsystem. The address space ID is a 2-byte hexadecimal number; the JOBNAME field shows the related job.

AUDITCONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field as a programming interface. The AUDITCONCERN field can contain one or more concerns separated by commas.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 351. IMS_PSB NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

CLASS

This field specifies the resource class used to secure the IMS PSB (for example, IIMS). Maximum length: 8 characters.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

IMSID

This field specifies the IMS subsystem identification of the IMS subsystem where the IMS transaction is run. Maximum length: 8 characters.

JOBID

This field contains the JES job ID of the IMS subsystem. Maximum length: 8 characters.

JOBNAME

This field contains the JES job name of the IMS subsystem. Maximum length: 8 characters.

PSBNAME

This field specifies the program specification block (PSB) name. Maximum length: 8 characters.

QUALIFIED_RESOURCE

This field specifies the qualified resource name. It is the concatenation of the RESOURCE_LOCATION and the RESOURCE separated by a colon, for example: IPO1.IMS.IMS10CR1.PSB:DFSSAM04. Maximum length: 44 characters.

RACF_ACL

This repeated field displays the access and conditional access lists of a profile. This field can be used for output on the SORTLIST, DISPLAY, and (D)SUMMARY commands only. The display contains userid, access, ACL id, conditional class, and conditional profile name. The default output length is 45 characters, but the profile name can be up to 255 characters so the maximum output length of RACF_ACL is 290 characters.

Use the EXPLODE output modifier for a complete access list including access per user through each connect group. Use the RESOLVE output modifier for a resolved access list showing the highest access of each user or group. Use the EFFECTIVE modifier to extend the resolved access list into the effective one, which also includes access due to operations or group operations. Be aware that connect information is needed for RESOLVE, EFFECTIVE and EXPLODE. You can use the UNIVERSAL modifier to force collection of all relevant data. The SCOPE modifier extends administrative access control to the modifiers EXPLODE, RESOLVE, and EFFECTIVE. To print the ids, the access levels, or both, the ACLACCESS, ACLID and ACLIDACCESS formats can be used. See "Format names for input and output" on page 810.

RACF_CLASS

This field contains the resource class of the profile that protects the resource. The resource class can be a member class or a grouping class. The RACF_PROFILE and RACF_CLASS fields are part of the repeat group of RACF information. Maximum length: 8 characters.

RACF_PROFILE

This field contains the name of the profile that protects the resource. The profile can be a member class profile or a grouping class profile. The RACF_PROFILE and RACF_CLASS fields are part of the repeat group of RACF information. Maximum length: 13 characters.

RACF_UACC

This field contains the effective universal access authority (UACC) to the program. The UACC is determined from all grouping and non-grouping resource profiles that describe the program. Field values: NONE, READ, EXECUTE, UPDATE, CONTROL, or ALTER.

RESOURCE

This field specifies the resource name used to secure the IMS program specification block (PSB). Maximum length: 246 characters. Default length: 17 characters.

RESOURCE_LOCATION

This field indicates the environment where the resource is relevant. This field is the concatenation of several fixed strings, fields, and lookups, such as *system*.IMS.*jobname*.PSB. An example is IPO1.IMS.IMS10CR1.PSB. Maximum length: 21 characters.

STEPNAME

This field contains the step name associated with the IMS subsystem. Maximum length: 8 characters.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. This field length is 8 characters for compatibility with other NEWLIST types. Maximum length: 8 characters.

TRANSACTION

This is a repeat field that shows the transactions that reference the IMS program specification block (PSB). Maximum length: 8 characters.

VTAM_APPLID

This field specifies the VTAM application identifier (APPLID) for this IMS subsystem. Maximum length: 8 characters.

IMS_REGION: IMS subsystems

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•		•	•	•	•	•

This section documents the fields for the NEWLIST TYPE=IMS_REGION. This NEWLIST type lists one entry per active IMS subsystem for each system. An entry is uniquely identified by the following fields: SYSTEM, COMPLEX, ASID, and JOBNAME.

Field descriptions

The IMS_REGION NEWLIST provides the following fields for reporting.

ASID

This field contains the address space ID associated with the IMS subsystem. The address space ID is a 2-byte hexadecimal number; the JOBNAME field shows the related job.

AUDITCONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field as a programming interface. The AUDITCONCERN field can contain one or more concerns separated by commas.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 352. IMS_REGION NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

CLASS_APSB

This field shows the SAF resource class used for APSB security if APSB security is active. For details, see the SEC_ODBA field. This is the same resource class that was previously used for AGN security. APSB security is used for CPI-C and Open Data Base Access (ODBA) applications. The default class used by IMS for APSB security is AIMS. Maximum length: 8 characters.

CLASS_CMD

This field shows the SAF resource class used for IMS commands if security is activated for IMS commands. For details, see SEC_CMD* fields. The default class used by IMS for command security is CIMS. Maximum length: 8 characters.

CLASS_DB

This field shows the SAF resource class used for controlling access to databases. The default class used by IMS for database security is PIMS. Maximum length: 8 characters.

CLASS_FIELD

This field shows the SAF resource class used for controlling access to database field names. The default class used by IMS for database field security is FIMS. Maximum length: 8 characters.

CLASS_LTERM

This field shows the SAF resource class used for logical terminals (LTERM). The default class used by IMS for logical terminal security is LIMS. Maximum length: 8 characters.

CLASS_OTH

This field shows the SAF resource class used for controlling access to other resources. The default class used by IMS for other resource security is OIMS. Maximum length: 8 characters.

CLASS_OTMA

This field shows the SAF resource class used for controlling access through Online Transaction Manager Access. The default class used by IMS for OTMA security is RIMS. Maximum length: 8 characters.

CLASS_PSB

This field shows the SAF resource class used for IMS program specification blocks. The default class used by IMS for PSB security is IIMS. Maximum length: 8 characters.

CLASS_SEG

This field shows the SAF resource class used for IMS database segments. The default class used by IMS for database segment security is SIMS. Maximum length: 8 characters.

CLASS_TRAN

This field shows the SAF resource class used for IMS transactions if security is activated for IMS transactions. For details, see the SEC_TRANS_ACTIVE field). The default class used by IMS for transaction security is TIMS. Maximum length: 8 characters.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

IMS_LEVEL

This field identifies the IMS system release level of the active IMS region.

IMSID

This field identifies the IMS subsystem identification. Maximum length: 8 characters.

JOBID

This field contains the JES job ID of the IMS subsystem. Maximum length: 8 characters.

JOBNAME

This field contains the JES job name of the IMS subsystem. Maximum length: 8 characters.

RCLASS

This field specifies the resource class suffix. Maximum length: 7 characters.

REGION_TYPE

This field specifies the region type of the IMS subsystem. Field values: Online, DBRC, DL/I, and Batch.

REGION_USERID

This field contains the userid associated with the IMS subsystem. Maximum length: 8 characters.

SEC_AO_CMD

This field specifies how security is handled for automated operator CMD calls. The possible values are:

Allow – Automated operator commands are allowed. No security checking is performed.

Exit – An exit is used to determine if automated operator CMD calls are allowed.

RACF – RACF is used to determine if automated operator CMD calls are allowed.

R/E – RACF and an exit are used to determine if automated operator CMD calls are allowed.

SMU – SMU is used to determine if automated operator CMD calls are allowed.

SEC_AO_ICMD

This field specifies how security is handled for automated operator ICMD calls. The possible values are:

Allow – Automated operator commands are allowed. No security checking is performed.

Deny – No automated operators ICMD calls are allowed.

Exit – An exit is used to determine if automated operator ICMD calls are allowed.

RACF – RACF is used to determine if automated operator ICMD calls are allowed.

R/E – RACF and an exit are used to determine if automated operator ICMD calls are allowed.

SEC_CMD_ALL

This field specifies whether access to commands from static and ETO terminals is checked. Field value: Yes or No.

SEC_CMD_ETO

This field specifies whether access to commands from the ETO terminals is checked. Field value: Yes or No.

SEC_CONSOLE_CMD

This field specifies how console commands are handled. The possible values are:

Allow – Console commands are allowed. No security checking is performed.

Deny – No console commands are allowed.

Exit – An exit is used to determine if console commands are allowed.

RACF – RACF is used to determine if console commands are allowed.

R/E – RACF and an exit are used to determine if console commands are allowed.

SEC_MULTI

This field specifies whether a static user can sign on to multiple static sessions. Field value: Yes or No.

SEC_ODBA

This flag field specifies whether PSBs specified on an APSB call for an ODBA application are protected in the AIMS or A*xxxxxxx* general resource class. Field value: Yes or No.

SEC_PR_CMD_ALL

This field refers to the security settings on the EXEC PARM statement. This field specifies whether access checking is required for commands entered from static and ETO-defined terminals. Field value: Yes or No.

SEC_PR_CMD_ETO

This field refers to the security settings on the EXEC PARM statement. This field specifies whether access checking is required for commands entered from ETO-defined terminals. Field value: Yes or No.

SEC_PR_FUSER

This field refers to the security settings on the EXEC PARM statement and specifies whether user verification is forced. Field value: Yes or No.

SEC_PR_MULTI

This field refers to the security settings on the EXEC PARM statement and specifies whether a static user can sign on to multiple static sessions. Field value: Yes or No.

SEC_PR_PASSWORD_UPPER

This field refers to the security settings on the EXEC PARM statement and specifies whether a password is changed to uppercase when entered. Field value: Yes or No.

SEC_PR_USER

This field refers to the security settings on the EXEC PARM statement and specifies whether user verification is to be performed. Field value: Yes or No.

SEC_RACF_AVAIL

This field specifies that RACF is available for transaction authorization. Field value: Yes or No.

SEC_RASEXIT

This field specifies that resource checking is performed using a resource access security (RAS) exit. Field value: Yes or No.

SEC_RASRACF

This field specifies that resource checking is performed using a RACROUTE call. Field value: Yes or No.

SEC_RE_CMD_ALL

This field refers to the security setting, as entered on the /NRESTART or /ERESTART MTO command or to the console WTOR during IMS system startup, and specifies whether command access is verified for static and ETO-defined terminals. This field is empty if a command security setting is not specified. Field value: Yes or No.

SEC_RE_CMD_ETO

This field refers to the security setting, as entered on the /NRESTART or /ERESTART MTO command or to the console WTOR during IMS system startup, and specifies whether command access is verified for ETO-defined terminals. This field is empty if a command security setting is not specified. Field value: Yes or No.

SEC_RE_MULTI

This field refers to the security setting, as entered on the /NRESTART or /ERESTART MTO command or to the console WTOR during IMS system

startup, and specifies whether a static user can sign on to multiple static sessions. This field is empty if a multiple session setting is not specified. Field value: Yes or No.

SEC_RE_TRANS

This field refers to the security setting, as entered on the /NRESTART or /ERESTART MTO command or to the console WTOR during IMS system startup, and specifies whether transaction authorization is checked. This field is empty if a transaction security setting is not specified. Field value: Yes or No.

SEC_RE_USER

This field refers to the security setting, as entered on the /NRESTART or /ERESTART MTO command or to the console WTOR during IMS system startup, and specifies whether the user verification is to be performed. This field is empty if a user verification setting is not specified. Field value: Yes or No.

SEC_SD_CMD_ALL

This field refers to the security setting as specified during system definition and specifies whether command access is verified for static and ETO-defined terminals. Field value: Yes or No.

SEC_SD_CMD_ETO

This field refers to the security setting as specified during system definition and specifies whether command access is verified for ETO-defined terminals. Field value: Yes or No.

SEC_SD_ENH

This field refers to the security setting as specified during system definition and specifies whether enhanced security has been requested. Field value: Yes or No.

SEC_SD_FTRANS

This field refers to the security setting as specified during system definition and specifies whether transaction authorization is forced. Forcing authorization prevents transaction authorization processing from being overridden and inactivated. Field value: Yes or No.

SEC_SD_FUSER

This field refers to the security setting as specified during system definition and specifies whether user verification is forced. Forcing authorization prevents transaction authorization processing from being overridden and inactivated. Field value: Yes or No.

SEC_SD_MULTI

This field refers to the security setting as specified during system definition and specifies whether a static user can sign on to multiple static sessions. Field value: Yes or No.

SEC_SD_RACFTERM

This field refers to the security setting as specified flag during system definition and specifies whether RACF transaction authorization and sign on processing is required. Field value: Yes or No.

SEC_SD_TRANS

This field refers to the security setting as specified during system definition and specifies whether transaction authorization is performed. Field value: Yes or No.

SEC_SD_USER

This field refers to the security setting as specified during system definition and specifies whether user verification is performed. Field value: Yes or No.

SEC_TCO_RACF

This field specifies whether RACF is used for authorization in time-controlled operation (TCO) requests. Field value: Yes or No.

SEC_TRANS

This field specifies whether transaction authorization checks are performed. Field value: Yes or No.

SEC_TRANS_ACTIVE

This field specifies whether transaction authorization checking is active within the IMS subsystem. Field value: Yes or No.

SEC_USER

This field specifies whether userid verification is performed within the IMS subsystem. Field value: Yes or No.

SEC_USER_ACTIVE

This field specifies whether the userid verification is active within the IMS subsystem. Field value: Yes or No.

SEC_VIOL_LIMIT

This field specifies the maximum number of terminal and password security violations allowed prior to master terminal notification for:

- physical terminals
- transaction commands

STEPNAME

This field contains the step name associated with the IMS subsystem. Maximum length: 8 characters.

SUBSYS_CRC

This field specifies the console command character that is used to enter commands from a console. Length: 1 character.

SVCNO

This field specifies the Type 2 SVC number that is used by the IMS subsystem.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. This field has a maximum length of 8 characters for compatibility with other NEWLIST types.

VTAM_APPLID

This field specifies the specific VTAM application identifier (APPLID) for the IMS subsystem. Maximum length: 8 characters.

IMS_TRANSACTION: IMS transactions

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
				•	•	•

This section documents the fields for the NEWLIST TYPE=IMS_TRANSACTION. This NEWLIST type lists one entry per active IMS transaction for an IMS subsystem in each system. An entry is uniquely identified by the following fields: SYSTEM, COMPLEX, ASID, JOBNAME. and TRANSACTION.

Field descriptions

The IMS_TRANSACTION NEWLIST provides the following fields for reporting.

ASID

This field contains the address space ID associated with the IMS subsystem. The address space ID is a 2-byte hexadecimal number; the JOBNAME field shows the related job.

AUDITCONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field. The AUDITCONCERN field can contain one or more concerns separated by commas.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 353. IMS_TRANSACTION NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

CLASS

This field specifies the resource class used to secure the IMS transaction (for example TIMS). Maximum length: 8 characters.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

IMSID

This field specifies the IMS subsystem identification of the IMS subsystem where the IMS transaction is run. Maximum length: 8 characters.

JOBID

This field contains the JES job ID of the IMS subsystem. Maximum length: 8 characters.

JOBNAME

This field contains the JES job name of the IMS subsystem. Maximum length: 8 characters.

PSBNAME

This field specifies the program specification block (PSB) that is associated with the IMS transaction. Maximum length: 8 characters.

QUALIFIED_RESOURCE

This field specifies the qualified resource name. It is the concatenation of the RESOURCE_LOCATION and the RESOURCE separated by a colon, for example: IPO1.IMS.IMS10CR1.TRN:ADDINVNT Maximum length: 30 characters.

RACF_ACL

This repeated field can be used to display the access and conditional access lists of a profile. It can only be used for output on the SORTLIST, DISPLAY, and (D)SUMMARY commands. The display contains userid, access, ACL id, conditional class, and conditional profile name. The default output length is 45 characters, but the profile name can be up to 255 characters so the maximum output length of RACF_ACL is 290 characters.

Use the EXPLODE output modifier for a complete access list including access per user through each connect group. Use the RESOLVE output modifier for a resolved access list showing the highest access of each user or group. Use EFFECTIVE to extend the resolved access list into the effective one, which also includes access due to operations or group operations. Be aware that connect information is needed for RESOLVE, EFFECTIVE and EXPLODE. You can use the UNIVERSAL modifier to force collection of all relevant data. The SCOPE modifier can be used to extend the modifiers EXPLODE, RESOLVE, and EFFECTIVE with administrative access. To print the ids, the access levels, or both, the ACLACCESS, ACLID and ACLIDACCESS formats can be used. See "Format names for input and output" on page 810.

RACF_CLASS

This field contains the resource class of the profile that protects the resource. The resource class can be a member class or a grouping class. The RACF_PROFILE and RACF_CLASS fields are part of the repeat group of RACF information. Maximum length: 8 characters.

RACF_PROFILE

This field contains the name of the profile that protects the resource. The profile can be a member class profile or a grouping class profile. The RACF_PROFILE and RACF_CLASS fields are part of the repeat group of RACF information. Maximum length: 13 characters.

RACF_UACC

This field contains the effective universal access authority (UACC) to the program. The UACC is determined from all grouping and non-grouping

resource profiles that describe the program. Field values: NONE, READ, EXECUTE, UPDATE, CONTROL, or ALTER.

RESOURCE

This field specifies the resource name used to secure the IMS transaction. Maximum length: 246 characters. Default length: 13 characters.

RESOURCE_LOCATION

This field indicates the environment where the resource is relevant. This field is the concatenation of several fixed strings, fields, and lookups, such as *system*.IMS.*jobname*.PSB. An example is IPO1.IMS.IMS10CR1.PSB. Maximum length: 21 characters.

STEPNAME

This field contains the step name associated with the IMS subsystem. Maximum length: 8 characters.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. The field length is 8 characters for compatibility with other NEWLIST types. Maximum length: 8 characters.

TRAN_CLASS

This field specifies the name of the transaction class for the IMS transaction.

TRANSACTION

This field specifies the name of the IMS transaction. Maximum length: 8 characters.

VTAM_APPLID

This field specifies the VTAM application identifier (APPLID) for this IMS subsystem. Maximum length: 8 characters.

IOAPP: I/O Appendages

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The I/O Appendages (IOAPP) NEWLIST (NEWLIST TYPE=IOAPP) describes authorized I/O appendages. Each entry in this NEWLIST can be uniquely identified by the fields SYSTEM ID or SYSTEM NAME.

Field descriptions

The IOAPP NEWLIST provides the following fields for reporting.

ADDRESS

This field contains the address of the default I/O appendage module, if one resides in-storage. This is the appendage used, unless the user has an appendage in an authorized STEPLIB or in the link list. See also the CONTENT field. The EXIT NEWLIST describes the I/O appendage routine in detail.. See "EXIT: System Exits" on page 1027.

Note: All possible I/O appendages (including those that can only be used with a STEPLIB) are reported by the REPORT AC1.

AUDITCONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field. The following table lists the audit concerns currently defined:

- Non-default Appendage

  An appendage other than IGG019E4. You should review this appendage.
- Altered Default Appendage

  Appendage IGG019E4 with non-default TYPE values. You should review the reason the TYPE values are set to non-default values.
- Added automatically by MVS

  Appendage IGG019E4 with default TYPE values. This appendage is not added automatically.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 354. IOAPP NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. The complex name can come from the ALLOC COMPLEX parameter or default to a system name.

CONTENT, CONTENTS

A string containing up to the first 256 bytes of the appendage, which usually include the eye catcher. The default output length of this string is 128 characters (containing the first 128 bytes of the appendage). In the default output format, the readable text from the contents is shown; the non-printable parts of the contents have been replaced by one or two dots. This is the appendage used, unless the user has an appendage in an authorized STEPLIB. See also the ADDRESS field.

Note: All possible I/O appendages (including those that can only be used with a STEPLIB) are reported by the REPORT AC1.

DEFAULT

This flag field indicates whether the I/O appendage conforms to the (IBM-defined) default. An appendage conforms to the default if both the authorization and the types match. See also the TYPE and DEFAULTTYPE fields.

DEFAULTTYPE

This repeated field indicates the (IBM-defined) default types for which the I/O appendage is authorized. Each appendage belongs to at least one, and at most five, default types. See the TYPE field for a table of values. See also the DEFAULT field.

DESCRIPTION, DESC

This text field contains a description of (the function of) the I/O appendage.

ID

The ID of the authorized I/O appendage. This is a two-character string that completes the required prefix IGG019, for example, ID EA indicates the I/O appendage IGG019EA. See also the NAME field.

NAME

The name of the authorized I/O appendage. This is an eight-character string that contains the full name of the I/O appendage. All names start with the required prefix IGG019. See also the ID field.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. The field length is 8 characters for compatibility with other NEWLIST types.

TYPE

This repeated field indicates the types for which the I/O appendage is authorized. Each appendage belongs to at least one, and at most five, types. The TYPE values are listed in the following table.

Table 355. TYPE values

I/O appendage types
ABE Abnormal End
CHE Channel End
EOE End of Extent
PCI Program Controlled Interrupt
SIO Start I/O

See also the DEFAULT and DEFAULTTYPE fields.

WHERE

A string indicating the virtual storage area where the appendage resides. This is the appendage used, unless the user has an appendage in an authorized STEPLIB. See also the ADDRESS field.

Note: All possible I/O appendages (including those that can only be used with a STEPLIB) are reported by the REPORT AC1 NEWLIST.

Table 356 on page 1054 lists the possible WHERE values and their meaning. Areas starting with an E reside above 16 MB in virtual storage.

Table 356. IOAPP - WHERE values and descriptions

WHERE value	Meaning
CSA	Common Storage Area
ECSA	Extended Common Storage Area
EFLPA	Extended Fixed Link Pack Area

IP: Profile information for TCP/IP configuration

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

You can use the IP configuration `NEWLIST` statements to select and report on information in the TCP/IP stack configuration. These `NEWLIST`s are supported in zSecure Audit and zSecure Alert.

Each record in the `IP_RESOLVER NEWLIST` is associated with a particular CS Resolver configuration, uniquely identified by the `COMPLEX`, `SYSNAME`, `SYSPLEX`, and `SYSTEM` fields. Each record in the other IP configuration newlists is associated with a particular TCP/IP stack, uniquely identified by the common fields: `COMPLEX`, `STACK`, `SYSNAME`, `SYSPLEX`, and `SYSTEM`. See “Common fields” on page 1055.

In addition to the common fields, each `NEWLIST` has its own fields. The following sections describe IP `NEWLIST` types.

"IP_VIPA: TCP/IP VIPA configuration" on page 1087

In addition to creating these reports using the CARLa NEWLIST command, you can also generate them using the Resources function available on the zSecure Audit menu. See Chapter 4, "Resource reports," on page 383.

You can also process TCP/IP stack configuration information by analyzing SMF data from the TCP/IP profile event record (SMF record type 119, subtype 4) using the SMF reporting functions or the SMF NEWLIST. For details, see Chapter 7, "SMF and HTTP Reporting (Events menu)," on page 545 and the IP* fields documented in "SMF: SMF records" on page 1276.

The TCP/IP stack configuration information is collected by the zSecure Collect program. Collection is enabled and disabled using the TCPIP configuration parameter. For details, see Chapter 16, "zSecure Collect for z/OS," on page 1591.

Common fields

Each record in the IP configuration newlists is associated with a particular TCP/IP stack, uniquely identified by the following fields: COMPLEX, STACK, SYSNAME, SYSPLEX, and SYSTEM fields. These fields are common to all TCP/IP configuration newlists.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The COMPLEX field identifies the security complex that contains the system. The security complex value can come from the ALLOC COMPLEX parameter or can default to the security node or sysplex name.

STACK

The STACK field provides the stack name which is the name of the started task procedure running the stack.

SYSNAME

The SYSNAME field identifies the name of the system. This value is used as part of the SAF resource name in some NEWLIST types.

SYSPLEX

The SYSPLEX field provides the name of the sysplex that the SYSTEM is a part of, if applicable.

SYSTEM

The SYSTEM field is the name of the MVS system, which is equal to the SMF system ID.

For more information about TCP/IP configuration, see the *z/OS Communications Server: IP Configuration Guide (SC31-8776)* at http://publib.boulder.ibm.com/infocenter/zos/v1r11/topic/com.ibm.zos.r11.halz001/toc.htm.

IP_AUTOLOG: TCP/IP autolog configuration

The IP_AUTOLOG NEWLIST selects and reports on autolog configuration data for TCP/IP stacks. The information includes lists of MVS started procedures to be initiated by the Autolog task when TCP/IP stacks are started. You can use the

following fields to select, exclude, and list data as required. In addition to these fields, each record is uniquely identified by the following fields that are common to all TCP/IP configuration records: COMPLEX, SYSTEM, STACK, SYSNAME, SYSPLEX, and SYSTEM. For information about these fields, see "Common fields" on page 1055.

You can change the values for these fields using AUTOLOG statements. For more information, see the *z/OS Communications Server: IP Configuration Guide (SC31-8776)* at http://publib.boulder.ibm.com/infocenter/zos/v1r11/topic/com.ibm.zos.r11.halz001/toc.htm.

Field descriptions

The IP_AUTOLOG NEWLIST provides the following fields for reporting.

JOBNAME

Contains the name of the job for the PORT reservation statement. This value can be identical to the value in the PROCNAME field. However, for z/OS UNIX jobs that create listener threads, the value is not the same. If the JOBNAME value is missing, the job name is taken from the PROCNAME field.

OPTIONS

Repeated flag field provides information about the current status of the IP autolog stack configuration options. This field can have the following values:

DELAYSTART DVIPA
The AUTOLOG procedure starts after the TCP/IP stack has joined the sysplex group and has processed its dynamic VIPA configuration.

DELAYSTART TTLS
The AUTOLOG procedure starts after the Policy Agent has successfully installed the AT-TLS policy in the TCP/IP stack and AT-TLS services are available.

PARMSTRING

The parameter string to be added following the START *procedure_name*, where *procedure_name* is the value is found in the PROCNAME field.

PROCNAME

Contains the name of a procedure that the TCP/IP address space must start.

WAIT

If a procedure is still active when TCP/IP is trying to AUTOLOG the procedure during the TCP/IP startup process, this value specifies the number of minutes that TCP/IP waits for the procedure to shut down before attempting to start it again. This situation can occur when a procedure was not shutdown the last time that TCP/IP was shutdown. TCP/IP checks if the procedure has shutdown every ten seconds until the specified time interval expires and restarts the procedure as soon as the procedure has been shutdown. If the shutdown is detected before the time interval expires, the procedure is restarted. If the procedure is still active when the time interval specified by wait expires, then TCP/IP cancels and restarts the procedure.

If WAIT= *0*, TCP/IP does not cancel or restart any active procedures during the initialization process.

IP_INTERFACE: TCP/IP interface configuration

The IP_INTERFACE NEWLIST selects and reports on interface configuration data for TCP/IP stacks. You can use the following fields to select, exclude, and list data as

required. In addition to these fields, each record is uniquely identified by the following fields that are common to all TCP/IP configuration records: COMPLEX, SYSTEM, STACK, SYSNAME, SYSPLEX, and SYSTEM. For information about these fields, see "Common fields" on page 1055.

Field descriptions

The IP_INTERFACE NEWLIST provides the following fields for reporting.

ASSOC_NAME

Provides the associated name for the interface, which can be the name for a Device, OSA-Express port, or a TRLE definition depending on the interface type.

CHPID

Provides the IQD Channel Path Identifier (CHPID) for the HiperSockets interface.

INDEX

Provides the positive number assigned to the interface by the TCP/IP stack when the stack processed the configuration statement for the interface. The index value is used heavily by SNMP as the identifier of an interface for a stack because it is easier to use a number than a name.

INTERFACE

The INTERFACE field contains the name of an IPv4 or IPv6 interface.

INTFID

The INTFID field contains the configured interface ID. This ID is used to form the link-local address for the interface. The value is also appended to any manually configured prefixes for the interface to form complete IPv6 addresses on the interface.

IP

The IP repeat group field provides the IPv4 and IPv6 addresses associated with the interface.

IPMASK

Repeat group field provides the IPv4 subnet masks of the IPv4 addresses associated with the interface. For IPv6 addresses, the IPMASK field is empty, but not missing.

OPTIONS

A repeated flag field that provides information about the settings for the IP stack interface configuration options. Table 357 lists the available configuration options.

Table 357. TCP/IP stack: Interface Configuration - configuration options available

Option	Header
INTERFACE	The INTERFACE statement was employed (as opposed to DEVICE, LINK, or HOME statements).
AUTORESTART	In the event of a device failure, the TCP/IP address space attempts to reactivate the device.
NOAUTORESTART	For most device failures, the TCP/IP address space does not attempt to reactivate this device.
IPBCAST	The link both sends and receives IP broadcast packets.

Table 357. TCP/IP stack: Interface Configuration - configuration options available (continued)

Option	Header
MONSYSPLEX	Sysplex autonomics monitor the status of the link.
NOMONSYSPLEX	Sysplex autonomics do not monitor the status of the link.
DYNVLANREG	If a VLAN ID is configured for this link, it is dynamically registered with the physical switches on the corresponding LAN.
NODYNVLANREG	If a VLAN ID is configured for this link, it must be manually registered with the physical switches on the corresponding LAN.
VMAC ROUTEALL	All IP traffic destined to the virtual MAC is forwarded by the OSA-Express device to the TCP/IP stack. If VMAC_ADDRESS is missing, the OSA-Express feature generates a virtual MAC address.
VMAC ROUTELCL	Only traffic destined to the virtual MAC and whose destination IP address is registered with the OSA-Express device by this TCP/IP stack is forwarded by the OSA-Express. If VMAC_ADDRESS is missing, the OSA-Express feature generates a virtual MAC address.
CHECKSUM	Inbound checksum calculation is performed for all packets received on this interface.
NOCHECKSUM	Inbound checksum calculation is not performed for any packets received on this interface.
ISOLATE	OSA-Express is being prevented from routing packets directly to another TCP/IP stack that share the OSA. In this mode, OSA-Express discards any packets when the next hop address was registered by another stack that share the OSA. Packets can flow between two stacks that share the OSA only by first going through a router on the LAN.
NOISOLATE	Packets are routed directly between TCP/IP stacks sharing the OSA. In this mode, if the next hop address was registered by another stack that share the OSA adapter, then OSA-Express routes the packet directly to the sharing stack without putting the packet on the external LAN.

PFXLEN

A repeat group field that shows the prefix lengths for the subnet address of the IPv4 and IPv6 addresses associated with the interface.

SECCLASS

Provides the security class used for IP filtering with this interface. Valid security classes are integers in the range 1 - 255. The default value is 255.

SOURCEVIPA_INTERFACE

The name of the previously defined static VIPA interface which is used for `SOURCEVIPA`.

TYPE

The TYPE field identifies the Interface type. Table 358 on page 1059 lists the available types.

Table 358. Possible values for the Interface type

Interface type	Description
LOOPBACK6	Loop back interface. One of the IPv6 addresses associated with the interface is ::1. Additional loopback addresses can be defined.
IPAQENET	OSA-Express QDIO Ethernet, OSA-Express2, or OSA-Express3 interface for IPv4
IPAQENET6	OSA-Express QDIO Ethernet or Fast Ethernet interface for IPv6.
IPAQIDIO6	IPv6 HiperSockets interface.
MPCPTP6	MPC Point-To-Point Data Link Control interface. The interface can be used to carry IPv6 traffic over ESCON channels, over XCF links in a sysplex, or between z/OS Communications Server images using the simulated device provided by the IUTSAMEH function in VTAM.
VIRTUAL6 S	Static virtual interface for IPv6. The interface is not associated with real hardware and is used for fault tolerance support.
IPAQIDIO	MPCIPA for HiperSockets - Another TCP/IP within the same CPC.
MPCPTP	MPC Point-To-Point Data Link Control interface. The interface can be used to carry IPv4 traffic over ESCON channels or between z/OS Communications Server images using the simulated device provided by the IUTSAMEH function in VTAM.
VIRTUAL	Static virtual interface for IPv4. The interface is not associated with real hardware and is used for fault tolerance support.
LOOPBACK	Loop back interface. One of the IPv4 addresses associated with the interface is 127.0.0.1. Additional loopback addresses can be defined.

VLAN_ID

Contains the Virtual LAN identifier value. Valid VLAN IDs are in the range 1 - 4094.

VMAC_ADDRESS

The virtual MAC address. The OSA-Express device uses this address rather than the physical MAC address of the device for all IPv4 packets sent to and received from this TCP/IP stack. If VMAC_ADDRESS is missing, the OSA-Express device generates a virtual MAC address.

IP_NETACCESS: TCP/IP network access control configuration

The IP_NETACCESS NEWLIST select and report on the network access control configuration data for TCP/IP stacks. You can use the following fields to select, exclude, and list data as required. In addition to these fields, each record is uniquely identified by the following fields that are common to all TCP/IP configuration records: COMPLEX, SYSTEM, STACK, SYSNAME, SYSPLEX, and SYSTEM. For information about these fields, see "Common fields" on page 1055.

The field values reported in the IP_NETACCESS NEWLIST can be changed through the use of NETACCESS statements. For more information, see the *z/OS Communications Server: IP Configuration Guide (SC31-8776)* at http://publib.boulder.ibm.com/infocenter/zos/v1r11/topic/com.ibm.zos.r11.halz001/toc.htm.

Field descriptions

The IP_NETACCESS NEWLIST provides the following fields for reporting.

INBOUND

The INBOUND flag field indicates whether network access control checking is enabled for inbound socket commands.

IP

Specifies an IP address or value that identifies the network or networks that require security product access control for user requests. This field can have the following values:

IP address
Security product access control of user requests is required for the network with the specified IP address.

DEFAULT
Security product access control of user requests is required for any networks not specifically defined by other NETACCESS statement entries.

DEFAULTHOME
Security product access control of user requests is required for all IP addresses that are local to this stack and not specifically defined by other NETACCESS statement entries.

IPMASK

Contains the IPv4 subnet mask. If the destination address is in IPV6 format, this field is missing.

OUTBOUND

Flag field that indicates whether network access control checking is enabled for outbound socket commands.

PFXLEN

The PFXLEN field contains the prefix length of the Subnet address.

RACF_ACL

This repeated field can be used to display the access and conditional access lists of a profile. It can only be used for output on the SORTLIST, DISPLAY, and (D)SUMMARY commands. The display contains userid, access, ACL id, conditional class, and the conditional profile name. The default output length is 45 characters, but the profile name can be 255 characters so the maximum output length is 290 characters.

Use the EXPLODE output modifier for a complete access list that includes access per user through each connect group. Use the RESOLVE output modifier for a resolved access list showing the highest access of each user or group. Use the EFFECTIVE output modifier to extend the resolved access list into the effective one, which also includes access due to operations or group operations. Be aware that connect information is needed for RESOLVE, EFFECTIVE and EXPLODE, so it works best if specified in the scope of a NEWLIST, while there are no outer selections or with the UNIVERSAL modifier specified to force collection of all relevant data. The SCOPE modifier can be used to extend the modifiers EXPLODE, RESOLVE, and EFFECTIVE with administrative access. To print the ids, the access levels, or both, the ACLACCESS, ACLID and ACLIDACCESS formats can be used. See “Format names for input and output” on page 810.

RACF_PROFILE

Identifies the profile which protects the resource identified in the IP_RESOURCE field. The profile is simulated with the current RACF database.

RESNAME

Contains the last qualifier of the resource name found in the RESOURCE field. Effective user IDs permitted to this resource are allowed to access the network.

RESOURCE

Identifies an SAF SERVAUTH resource. Effective user IDs with permissions for this resource can access the network. The resource name has the following format: EZB..*sysname.tcpname.resname* where the variable identifiers have the following meanings:

sysname is the value of the MVS &SYSNAME. system symbol. The value comes from the SYSNAME field.

tcpname is the name of the procedure used to start the TCP/IP stack. The value comes from the STACK field.

resname is the 8-character value following the network specification in a statement. The value comes from the RESNAME field.

IP_PORT: TCP/IP port configuration

The IP_PORT NEWLIST selects and reports on port configuration data for TCP/IP stacks. You can use the following fields to select, exclude, and list data as required. In addition to these fields, each record is uniquely identified by the following fields that are common to all TCP/IP configuration records: COMPLEX, SYSTEM, STACK, SYSNAME, SYSPLEX, and SYSTEM. For information about these fields, see "Common fields" on page 1055.

The field values for the IP_PORT NEWLIST fields can be changed with PORT and PORTRANGE statements. For more information, see the *z/OS Communications Server: IP Configuration Guide (SC31-8776)* at http://publib.boulder.ibm.com/infocenter/zos/v1r11/topic/com.ibm.zos.r11.halz001/toc.htm.

Field descriptions

The IP_PORT NEWLIST provides the following fields for reporting.

AUDITCONCERN

Indicates the reason for the audit priority. Do not rely on the exact value of this field in your programs. The contents is subject to change.

This field can contain one or more concerns separated by commas. The following audit concerns have been defined:

Because there is no SAF parameter, any user or program can bind to a privileged [TCP|UDP] port [*begin_port-end_port*|*port***] under jobname** *jobname* **(filter) by default, thus masquerading as a legitimate service and receive passwords**

The TCP/IP stack configuration contains a PORT or PORTRANGE statement pertaining to TCP or UDP ports *begin_port* to *end_port*, or to port *port*. The statement has a parameter jobname which specifies the MVS job names that can use the specified ports. Because the statement has no SAF parameter, no RACF resource is checked to verify that a user or program is permitted to bind to the ports. Unless a PORT statement with a more specific jobname filter has been specified to prohibit access, any user or program can bind to the ports using a job name that matches the name specified in the PORT or PORTRANGE statement. Thus, the user or program can masquerade as a legitimate service. The compromised service can then be used to steal passwords because the port, or at least one of the ports in range, is associated with the transmission of a clear text password.

Because there is no SAF parameter, any user or program can bind to a privileged [TCP|UDP] port [*begin_port-end_port*|*port*] under jobname *jobname* (filter) by default, thus masquerading as a legitimate service

The TCP/IP stack configuration contains a PORT or PORTRANGE statement pertaining to TCP or UDP ports *begin_port* to *end_port*, or to port *port*. The statement has a *jobname* parameter which specifies the MVS job name that can use the specified ports. no RACF resource is checked to verify that a user or program is permitted to bind to the ports. Unless a PORT statement with a more specific jobname filter has been specified to prohibit access, any user or program can bind to the ports using a job name that matches the name specified in the PORT or PORTRANGE statement. Thus, the user or program can masquerade as a legitimate service.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 359. IP_PORT NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

BEGIN_PORT

Contains the first port in a range of reserved ports. If ports have not been reserved (UNRSV=true), this field is missing. You can change this field value with PORT and PORTRANGE statements.

BIND

Contains the IP address *ipaddr* which is associated with the job name present in the JOBNAME field. When a job with the designated name binds to the IPv4 INADDR_ANY address, or to the IPv6 address in6addr_any, the bind is intercepted and converted to a bind to the IP address specified by *ipaddr*. Subsequent bind processing occurs as though the server instance had originally issued the bind to the IP address *ipaddr*. You can change this field value with PORT statements.

COUNT

Contains the number of ports in a range of reserved ports. If the ports are not reserved (UNRSV= true), this field is missing. The field value can change through the use of PORT and PORTRANGE statements.

END_PORT

Contains the last port in a range of reserved ports. If the ports are not reserved (UNRSV= true), this field is missing. You can change this field value with PORT and PORTRANGE statements.

JOBNAME

Specifies an MVS job name filter. If the value of the USE field is *JOBNAME*, then the JOBNAME field indicates which job names can use the ports in the BEGIN_PORT to END_PORT range, or any unreserved port in case the value of UNRSV is true. For

multiple TCP reservations for the same port or for multiple PORT UNRSV statements for the same protocol, the TCP/IP stack searches the PORT statements for the closest match (if any) to the application job name. The field value can change through the use of PORT and PORTRANGE statements.

OPTIONS

The OPTIONS repeated flag field provides information about the current status of IP interface settings. Table 360 lists the settings that are reported.

Table 360. TCP/IP Configuration IP_PORT - Interface settings reported

OPTION	Description
NOAUTOLOG	The TCP/IP address space is not to restart the server if it was stopped previously.
DELAYACKS	Transmission of acknowledgments is delayed when a packet is received with the PUSH bit on in the TCP header. By default, this setting only affects connections that use a port in the specified port range. The behavior can be overridden by specifying the NODELAYACKS parameter on the TCP/IP stack TCPCONFIG profile statement, or on any of the following statements used to configure the route used by the TCP connection: • The TCP/IP stack BEGINROUTES or GATEWAY profile statements • The Policy Agent RouteTable statement • The OMPROUTE configuration statements
NODELAYACKS	An acknowledgment is returned immediately when a packet is received with the PUSH bit on in the TCP header. Only connections that use this port are affected. Specifying the NODELAYACKS parameter on the PORTRANGE statement overrides the specification of the parameter on the TCP/IP stack TCPCONFIG profile statement, or on any of the following statements used to configure the route used by the TCP connection: • The TCP/IP stack BEGINROUTES or GATEWAY profile statements • The Policy Agent RouteTable statement • The OMPROUTE configuration statements
SHAREPORT	TCP/IP allows multiple listeners to listen on the same combination of port and interface. Incoming connection requests for a port are distributed among the listeners using a weighted round-robin distribution method based on the accept Efficiency Fractions (SEFs) of the listeners sharing the port.
SHAREPORTWLM	TCP/IP allows multiple listeners to listen on the same combination of port and interface. The listener selection is based on WLM server-specific recommendations, modified by the SEF values for each listener.
DENY	Access to unreserved ports is denied. The JOBNAME is an asterisk (*) in this case.
WHENLISTEN	Port access control is targeted to TCP applications acting as servers[10] that issue an explicit bind to a user-specified unreserved port. Permission to use the unreserved port is determined when a TCP listen command is issued. If a listen command is not issued, no access control check is made.

Table 360. TCP/IP Configuration IP_PORT - Interface settings reported (continued)

OPTION	Description
WHENBIND	Permission to use an unreserved port is determined when an explicit bind to a specific local port is issued. For the UDP protocol, it can affect UDP applications that bind to a specific local port. For the TCP protocol, it can affect TCP client applications that bind to a specific local port for outbound connections.

PORTRANGE

Indicates whether a PORTRANGE statement was used instead of a PORT statement. The field value can change through the use of PORT and PORTRANGE statements.

PROTOCOL

The PROTOCOL field specifies the protocol associated with a range of ports. The value can be TCP or UDP. You can use the PORT and PORTRANGE statements to change the value of this field.

RACF_ACL

This repeated field can be used to display the access and conditional access lists of a profile. It can only be used for output on the SORTLIST, DISPLAY, and (D)SUMMARY commands. The display contains userid, access, ACL id, conditional class, and the conditional profile name. The default output length is 45 characters, but the profile name can be 255 characters so the maximum output length is 290 characters.

Use the EXPLODE output modifier for a complete access list that includes access per user through each connect group. Use the RESOLVE output modifier for a resolved access list showing the highest access of each user or group. Use the EFFECTIVE output modifier to extend the resolved access list into the effective one, which also includes access due to operations or group operations. Be aware that connect information is needed for RESOLVE, EFFECTIVE and EXPLODE, so it works best if specified in the scope of a NEWLIST, while there are no outer selections or with the UNIVERSAL modifier specified to force collection of all relevant data. The SCOPE modifier can be used to extend the modifiers EXPLODE, RESOLVE, and EFFECTIVE with administrative access. To print the ids, the access levels, or both, the ACLACCESS, ACLID and ACLIDACCESS formats can be used. See "Format names for input and output" on page 810.

RACF_PROFILE

Identifies the profile which protects the RESOURCE *resource*. The profile is simulated with the current RACF database. You can use the PORT and PORTRANGE statements to change the value of this field.

RESNAME

Contains the last qualifier of the SAF SERVAUTH resource name present in the RESOURCE field. All ports in the BEGIN_PORT to END_PORT port range (or all unreserved ports in case UNRSV is true) are reserved for users that are permitted to this resource. You can use the PORT and PORTRANGE statements to change the value of this field.

RESOURCE

10. Applications acting as servers are able to accept incoming client TCP connections.

The name of a SAF SERVAUTH resource. All ports in the BEGIN_PORT to END_PORT port range (or all unreserved ports in case UNRSV is true) are reserved for users that are permitted to this resource.

You can use the PORT and PORTRANGE statements to change the value of this field.

The following code shows a sample resource.

```
EZB.PORTACCESS.sysname.tcpname.resname
```

where the variable identifiers have the following meanings:

- *sysname* is the value of the MVS &SYSNAME. system symbol, which is present in the SYSNAME field.
- *tcpname* is the name of the procedure used to start the TCP/IP stack. This value is also found in the STACK field
- *resname* is the 8-character value following the SAF keyword in a PORT or PORTRANGE statement. This value is also found in the RESNAME field.

UNRSV

The UNRSV flag field indicates whether a PORT UNRSV statement was used. Such statements indicate which applications or users are permitted to access application-specified unreserved ports. The following processing rules apply to PORT UNRSV statements:

- PORT UNRSV statements control access to all unreserved ports in the range 1 - 65535 unless RESTRICTLOWPORTS is configured. However, when RESTRICTLOWPORTS is configured, PORT UNRSV statements control access to unreserved ports above port 1023 only.
- For UDP, access control is applied when an application issues a bind to a particular port number to establish a local port. For TCP, access control is applied depending on the value of the WHENBIND or WHENLISTEN parameter.
- If neither DENY nor the SAF keyword is specified, an application that matches the protocol and specified job name on a PORT UNRSV statement can access unreserved ports. The job name can be an asterisk (*). If *DENY* is specified, all applications are denied access to unreserved ports for the specified protocol.
- If the SAF keyword is specified, applications that match the PORT UNRSV statement must also have user access to the SAF SERVAUTH resource to be permitted to access an unreserved port.

You can use PORT statements to change the value of this field.

USE

The USE field indicates how the port is used. Table 361 lists the possible use types. You can change this field value by using PORT and PORTRANGE statements.

Table 361. TCP/IP Configuration IP_PORT: Port use types

Port use type	Meaning
RESERVED	Specifies that the ports in the BEGIN_PORT to END_PORT range are not available for use by any user. If UNRSV=*true*, none of the unreserved ports are available.
AUTHPORT	Specifies that the ports in the BEGIN_PORT to END_PORT range are not available for use by any user except FTP. FTP can only use the ports if it has been configured to support the PASSIVEDATAPORTS option.
JOBNAME	The JOBNAME field contains a filter indicating which job names can use the ports in the BEGIN_PORT to END_PORT range (or unreserved ports in case UNRSV is true).

IP_RESOLVER: CS Resolver configuration

The IP_RESOLVER NEWLIST describes Communications Server (CS) Resolver configuration settings. The CS Resolver acts on behalf of programs as a client to:

- access name servers for providing name-to-address or address-to-name resolution
- allocate and read the TCPIP.DATA file
- establish TCP/IP stack affinity for certain socket APIs
- provide protocol and services information

Each record in an IP_RESOLVER NEWLIST is associated with a particular CS Resolver configuration, which is uniquely identified by the IP_RESOLVER NEWLIST key comprised of the common fields: COMPLEX, SYSNAME, SYSPLEX, and SYSTEM. See "Common fields" on page 1055.

Field descriptions

The IP_RESOLVER NEWLIST provides the following fields for reporting.

ALWAYSWTO

A flag field that indicates whether some TCP/IP servers, such as SMTP, SNMPQE, LPD, and miscellaneous server, issue all of their messages to the operator console as Write To Operator (WTO) messages in addition to sending messages to the server's MVS job log output. Because of the large volume of operator console messages that can result if ALWAYSWTO is set to YES, ALWAYSWTO is set to NO by default. With the default setting of NO, TCP/IP server messages are not issued as WTO messages.

For this field to be nonempty in report output, the ALWAYSWTO statement must be specified in the global TCPIP.DATA file.

AUDITCONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field. The audit concerns include the following:

- Any user can redirect all DNS queries from the user's address space

  Any user can control which resolver statements are used for name resolution because there is no resolver setup file with a GLOBALTCPIPDATA statement

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 362. IP_RESOLVER NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

AUTOQUIESCE
A flag field indicating whether the resolver will stop sending DNS queries to unresponsive name servers. In the resolver setup file, specify this field as a parameter of the UNRESPONSIVETHRESHOLD statement.

CACHE

A flag field that indicates whether caching is enabled for resolved DNS queries. System-wide caching is enabled by default. To explicitly enable system-wide caching, use the CACHE statement in the resolver setup file. To disable system-wide caching, use the NOCACHE statement in the resolver setup file; caching can also be disabled by specifying the NOCACHE statement in a TCPIP.DATA file.

CACHESIZE

A field that indicates the amount of storage that the resolver can allocate to manage cached records. The storage amount is specified by using the CACHESIZE statement in the resolver setup file. If the NOCACHE statement is specified, the CACHESIZE storage amount is ignored. The default cache size is 200 MB, where 1 MB represents 1048576 bytes.

COMMONSEARCH

A flag field indicating that the resolver uses a common search order for local host files for IPv4 and IPv6 name queries. By default, a different search order is used for IPv4 and IPv6 name queries. In the resolver setup file, use the COMMONSEARCH statement to specify a common search order, and use NOCOMMONSEARCH to specify a different search order.

DATASETPREFIX

A field that identifies the high-level qualifiers for dynamically allocated TCP/IP data sets. The default high-level qualifier is TCPIP. To specify different high-level qualifiers, use the DATASETPREFIX statement in a TCPIP.DATA file.

DBCS_TABLE_NAME

This field is an alias of the LOADDBCSTABLES field.

DEFAULTIPNODES

This field contains the fully-qualified z/OS UNIX file name or MVS data set name of the default IPNODES local host file. Local host files map host names to hard-coded IP addresses. The value of the DEFAULTIPNODES field signifies the final location where the local host file is searched.

In the resolver setup file, the DEFAULTIPNODES statement specifies the fully-qualified name of the default IPNODES local host file.

DEFAULTTCPIPDATA

This field identifies a fully-qualified z/OS UNIX file name or MVS data set name that is the last file searched by the resolver for TCPIP.DATA statements. This value is specified by the DEFAULTTCPIPDATA statement in the resolver setup file. If a DEFAULTTCPIPDATA statement is not specified in the resolver setup file, the default TCPIP.TCPIP.DATA file is searched.

DOMAIN

This field is an alias of the DOMAINORIGIN field.

DOMAINORIGIN, DOMAIN, SEARCH

A repeated field. Each entry is a domain origin that is appended to a host name to form the fully-qualified domain name of the host. A domain origin is appended, in the order listed, until an IP address is found or the list is exhausted. The domain origins are appended for name server queries and for local host table searches. A single domain origin can be specified by the DOMAINORIGIN and DOMAIN statements in a TCPIP.DATA file. Multiple domain origins can be specified by one or more SEARCH statements in a TCPIP.DATA file.

For this field to be nonempty in report output, the DOMAINORIGIN, DOMAIN, or SEARCH statement must be specified in the global TCPIP.DATA file.

GLOBALIPNODES

This field contains the fully-qualified z/OS UNIX file name or MVS data set name of the global IPNODES local host file. Local host files map host names to hard-coded IP addresses. The value of the GLOBALIPNODES field signifies the first location where the local host file is searched.

In the resolver setup file, the GLOBALIPNODES statement specifies the fully-qualified name of the global IPNODES local host file.

GLOBALTCPIPDATA

This field identifies the fully-qualified z/OS UNIX file name or MVS data set name that contains global TCPIP.DATA statements for the entire MVS image and for all TCP/IP data stacks. This value is specified by the GLOBALTCPIPDATA statement in the resolver setup file. It is the first file that the resolver searches for TCPIP.DATA statements.

GLOBALTCPIPDATA_SPEC

A flag field that indicates whether the resolver setup file contains the GLOBALTCPIPDATA statement. If the resolver setup file does not contain a GLOBALTCPIPDATA statement, or if the CS Resolver is not using a resolver setup file, the value of the GLOBALTCPIPDATA_SPEC field is No.

HOSTNAME

This field identifies the TCP host name of the z/OS CS server. The HOSTNAME statement in a TCPIP.DATA file specifies the TCP host name.

For this field to be nonempty in report output, the HOSTNAME statement must be included in the global TCPIP.DATA file.

LOADDBCSTABLES, DBCS_TABLE_NAME

A repeated field. Each field entry is the name of a DBCS translation table to be loaded by the FTP server and client. The LOADDBCSTABLES statement in a TCPIP.DATA file is used to specify DBCS translation tables.

For this field to be nonempty in report output, the LOADDBCSTABLES statement must be included in the global TCPIP.DATA file.

LOOKUP

This field specifies the order in which the DNS and local host file are to be used for name resolution. The LOOKUP field can have one of the following values: DNS, DNS LOCAL, LOCAL, LOCAL DNS.

For this field to be nonempty in report output, the LOOKUP statement must be included in the global TCPIP.DATA file.

DNS

For this value, only the domain name servers specified by the NSINTERADDR and NAMESERVER statements are used for name resolution. When system-wide

caching is enabled, the resolver first queries the resolver cache for entries provided by these name servers on previous name resolution attempts; if that query fails, the resolver then queries the domain name servers to resolve the resource name.

This value is specified in a TCPIP.DATA file by using the LOOKUP statement: LOOKUP DNS.

DNS LOCAL
For this value, the resolver first uses the resolver cache, if caching is enabled, for name resolution. If the resource name is not resolved, the resolver queries name servers directly. If the resource name is still not resolved, the resolver finally queries local host tables to resolve the resource name. DNS LOCAL signifies the default order in which the DNS and local host file are to be used for name resolution.

This value can be explicitly specified in a TCPIP.DATA file by using the LOOKUP statement: LOOKUP DNS LOCAL.

LOCAL
For this value, the resolver only uses the local host tables (for example, /etc/hosts, HOSTS.SITEINFO, or HOSTS.ADDRINFO) for name resolution.

This value is specified in a TCPIP.DATA file by using the LOOKUP statement: LOOKUP LOCAL.

LOCAL DNS
For this value, the resolver first uses local host tables for name resolution. If the resource name is not resolved, the resolver then queries the resolver cache, if caching is enabled. If there is still no resolution, then this is followed by direct queries to the name servers to resolve the resource name.

This value is specified in a TCPIP.DATA file by using the LOOKUP statement: LOOKUP LOCAL DNS.

MAXTTL

This field value specifies the maximum amount of time, in seconds, that the resolver is permitted to use the cached resource information obtained from a Domain Name System (DNS) server. The time-to-live value default is 2147483647 seconds.

In the resolver setup file, a MAXTTL statement can be employed to specify the time-to-live value.

NAMESERVER

This field is an alias of the NSINTERADDR field.

NSPORTADDR

This field identifies the name server port number. The port number pertains to all IP addresses in the NSINTERADDR field. The default port number is 53.

For this field to be nonempty in report output, the NSPORTADDR statement must be included in the global TCPIP.DATA file.

NSINTERADDR, NAMESERVER

A repeated field. Each entry is the IP address of a name server. The port number of the NSPORTADDR field pertains to all of these IP addresses.

For this field to be nonempty in report output, a NSINTERADDR or NAMESERVER statement must be specified in the global TCPIP.DATA file.

OPTIONS_NDOTS

A field of value *n* indicates that for domain names containing *n* periods or more, the resolver should look up the name *as is* before applying the DOMAINORIGIN or SEARCH statement settings. The default value is 1 period.

For this field to be nonempty in report output, the OPTIONS NDOTS statement must be specified in the global TCPIP.DATA file.

PREFERRED_ADDRESS

A repeat group field. PREFERRED_ADDRESS field values combined with up to 4 PREFERRED MASK field values (1 to 24) make up an ordered list of network numbers (subnets or networks) for the resolver to prefer if multiple addresses are returned as the result of a name query.

The ordered list sorts:

- addresses returned by gethostbyname calls
- IPv4 addresses returned for getaddrinfo calls

For this field to be nonempty in report output, the SORTLIST statement must be specified in the global TCPIP.DATA file.

PREFERRED_MASK

A repeat group field. Up to 4 PREFERRED_MASK field values (1 to 24) are combined with PREFERRED_ADDRESS field values to make up an ordered list of network numbers (subnets or networks) for the resolver to prefer if multiple addresses are returned as the result of a name query.

The ordered list sorts:

- addresses returned by gethostbyname calls
- IPv4 addresses returned for getaddrinfo calls

For this field to be nonempty in report output, the SORTLIST statement must be specified in the global TCPIP.DATA file.

RACF_ACL

This repeated field can be used to display the access and conditional access lists of a profile. It can only be used for output on the SORTLIST, DISPLAY, and (D)SUMMARY commands. The display contains userid, access, ACL id, conditional class, and the conditional profile name. The default output length is 45 characters, but the profile name can be 255 characters so the maximum output length is 290 characters.

Use the EXPLODE output modifier for a complete access list that includes access per user through each connect group. Use the RESOLVE output modifier for a resolved access list showing the highest access of each user or group. Use the EFFECTIVE output modifier to extend the resolved access list into the effective one, which also includes access due to operations or group operations. Be aware that connect information is needed for RESOLVE, EFFECTIVE and EXPLODE, so it works best if specified in the scope of a NEWLIST, while there are no outer selections or with the UNIVERSAL modifier specified to force collection of all relevant data. The SCOPE modifier can be used to extend the modifiers EXPLODE, RESOLVE, and EFFECTIVE with administrative access. To print the ids, the access levels, or both, the ACLACCESS, ACLID and ACLIDACCESS formats can be used. See "Format names for input and output" on page 810.

RESOLVERTIMEOUT

A field that specifies number of milliseconds that the resolver waits for a response from a name server when using the UDP communication protocol. The default timeout is 5000 milliseconds (5 seconds).

For this field to be nonempty in report output, the RESOLVERTIMEOUT statement must be specified the global TCPIP.DATA file.

RESOLVERUDPRETRIES

A field that specifies how many times (including retries) the resolver attempts to connect to the name server when using UDP datagrams. The default number of connection attempts is 1.

For this field to be nonempty in report output, the RESOLVERUDPRETRIES statement must be specified in the global TCPIP.DATA file.

RESOLVEVIA_TCP

A flag field that indicates whether the resolver uses the TCP protocol to communicate with the name server. The default communication protocol is UDP.

To specify usage of the TCP protocol, in a TCPIP.DATA file, use the statement RESOLVEVIA_TCP.

To explicitly specify usage of the UDP protocol, in a TCPIP.DATA file, use the statement RESOLVEVIA_UDP.

For this field to be nonempty in report output, the RESOLVEVIA statement must be specified in the global TCPIP.DATA file.

SEARCH

This field is an alias of the DOMAINORIGIN field.

SETUP_FILE

A field that lists the name of the resolver setup file, either an MVS data set name or a z/OS UNIX file name. This file contains resolver configuration statements.

If the CS Resolver does not use a resolver setup file, this field is empty in the report output.

SETUP_FILE_EMPLOYED

A flag field indicating whether the CS Resolver employs a resolver setup file.

SOCKTESTSTOR

A flag field that indicates whether TCP/IP C socket calls are being checked for storage access errors on the parameters to the call; by default, C socket calls are not checked for storage access errors.

To enable checking, specify the SOCKTESTSTOR statement in a TCPIP.DATA file.

To explicitly disable checking, specify SOCKNOTESTSTOR statement in a TCPIP.DATA file.

For this field to be nonempty in report output, a SOCKTESTSTOR or SOCKNOTESTSTOR statement must be specified in the global TCPIP.DATA file.

TCPIPJOBNAME, TCPIPUSERID

This field lists the member name of the procedure used to start the TCP/IP address space. The member name can be specified by the TCPIPJOBNAME or TCPIPUSERID statements in a TCPIP.DATA file. The TCPIPJOBNAME field should show as blanks for systems with multiple TCP/IP stacks.

For this field to be nonempty in report output, the TCPIPJOBNAME statement must be included in the global TCPIP.DATA file.

TCPIPUSERID

This field is an alias of the TCPIPJOBNAME field.

UNRESPONSIVETHRESHOLD

This field lists the threshold value that determines when the resolver declares a DNS name server to be unresponsive. The value is a percentage of the resolver queries occurring within a 5-minute sliding interval. If percentage of query failures to a name server is greater than or equal to the threshold percentage value, the resolver considers the name server to be unresponsive.

In the response setup file, the threshold value is specified by the UNRESPONSIVETHRESHOLD statement. If the AUTOQUIESCE parameter of the UNRESPONSIVETHRESHOLD statement is not specified, the default threshold is 25 percent. See "AUTOQUIESCE" on page 1067.

IP_ROUTE: TCP/IP route configuration

The IP_ROUTE NEWLIST selects and reports on route configuration data for TCP/IP stacks. You can use the following fields to select, exclude, and list data as required. In addition to these fields, each record is uniquely identified by the following fields that are common to all TCP/IP configuration records: COMPLEX, SYSTEM, STACK, SYSNAME, SYSPLEX, and SYSTEM. For information about these fields, see "Common fields" on page 1055.

The field values for the IP_ROUTE NEWLIST fields can be changed with BEGINROUTES statements. For more information, see the *z/OS Communications Server: IP Configuration Guide (SC31-8776)* at http://publib.boulder.ibm.com/infocenter/zos/v1r11/topic/com.ibm.zos.r11.halz001/toc.htm.

Field descriptions

The IP_ROUTE NEWLIST provides the following fields for reporting.

DSTIP

Specifies the destination IPv4 or IPv6 address. A DEFAULT keyword in this field specifies a default IPv4 route. A DEFAULT6 keyword in this field specifies a default IPv6 route. The field value can be changed through the use of BEGINROUTES statements.

INTERFACE

The name of the interface through which packets are sent to the destination. When the interface configuration statement is processed, this name value is indexed by the INTERFACE_INDEX field so the interface can be identified by a numeric value instead of a name.

INTERFACE_INDEX

A positive number assigned to the interface by the TCP/IP stack when the interface configuration statement was processed. In the SNMP protocol, this value is generally used to identify the interface for a stack because it is easier to use a number than a name.

IPMASK

Provides a BSD style address mask of an IPv4 destination address. For IPv6 addresses, the IPMASK field is empty, but not missing.

NEXTHOP_IP

Specifies the host IPv4 or IPv6 address of a gateway or router that you can reach directly, and that forwards packets for the destination network or host.

PFXLEN

The number of mask bits of an IPv4 destination address or the prefix length of an IPv6 destination address.

REPLACEABLE

Flag field that indicates that the static route can be replaced by OMPROUTE and router advertisements when a dynamic route to the same destination is discovered.

REPLACED

Flag field that indicates that the route is a replaceable static route that has been replaced by a dynamic route. The route is not currently being used by the TCP/IP stack.

IP_RULE: TCP/IP Rule Configuration

The IP_RULE NEWLIST selects and reports on the IP filter rule configuration data for TCP/IP stacks. You can use the following fields to select, exclude, and list data as required. In addition to these fields, each record is uniquely identified by the following fields that are common to all TCP/IP configuration records: COMPLEX, SYSTEM, STACK, SYSNAME, SYSPLEX, and SYSTEM. For information about these fields, see "Common fields" on page 1055.

The field values within an IP_RULE NEWLIST can be changed through the use of IPSEC statements. For more information, see the *z/OS Communications Server: IP Configuration Guide (SC31-8776)* at http://publib.boulder.ibm.com/infocenter/zos/v1r11/topic/com.ibm.zos.r11.halz001/toc.htm.

Field descriptions

The IP_RULE NEWLIST provides the following fields for reporting.

CODE

Specifies the Internet Control Message Protocol (ICMP) code for IP traffic. This field is only applicable when the PROTOCOL is ICMP and the TYPE field has a value other than asterisk (*). For IP traffic to be permitted by this rule, the ICMP code of the traffic must match the value in the CODE field. If the value of CODE is asterisk (*), any ICMP code matches. Also see the TYPE field.

DSTIP

Provides the destination IP address for the outbound rule. For outbound IP traffic to be permitted by this rule, the destination IP address of the traffic must match this parameter. For inbound IP traffic to be permitted by the generated inbound rule, the source IP address of the traffic must match this parameter.

DSTIPMASK

The DSTIPMASK field provides the destination IPv4 subnet mask. If the destination address is IPv6, this field is missing.

DSTPFXLEN

The DSTPFXLEN field provides the destination subnet address prefix length.

DSTPORT

For TCP or UDP traffic, the DSTPORT field specifies the destination port for the outbound rule and the source port for the generated inbound rule. Outbound

traffic is permitted if the destination port matches the DSTPORT value. Inbound traffic is permitted if the source port matches the DSTPORT value.

LOG

Flag field that indicates whether packet filter logging is enabled for the default filter rule.

PROTOCOL

Indicates the type of traffic that the rule applies to. For example, rules that permit or prevent IP traffic have the value `PROTOCOL=TCP`. The value can be any of the following protocol types: *ICMP*, *TCP*, *UDP*, *ICMPV6*, *OSPF*, and *nn* for traffic identified by protocol number `nn`.

ROUTING

The ROUTING field indicates the type of packet routing that this rule applies to.

Table 363. IP_RULE ROUTING field - possible values

Routing value	Meaning
LOCAL	Indicates that this rule applies to packets destined for this stack.
ROUTED	Indicates that this rule applies to packets being forwarded by this stack.
EITHER	Indicates that this rule applies to forwarded and non-forwarded packets.

SECCLASS

The SECCLASS field shows the Security class. The value can be an integer in the range 0 – 255 and has a default value of 0. A value of 0 matches any security class value coded on the corresponding profile statement which defines the interface.

SRCIP

The SRCIP field provides the source IP address for the outbound rule. For outbound IP traffic to be permitted by this rule, the source IP address of the traffic must match this parameter. For inbound IP traffic to be permitted by the generated inbound rule, the destination IP address of the traffic must match this parameter.

SRCIPMASK

The SRCIPMASK field provides the destination IPv4 subnet mask. If the source address is IPv6, this field is missing.

SRCPFXLEN

The SCRCPFXLEN field provides the prefix length for the source subnet address.

SRCPORT

For TCP or UDP traffic, the SRCPORT field specifies the source port for the outbound rule. For outbound IP traffic to be permitted by this rule, the source port of the traffic must match this parameter. For inbound IP traffic to be permitted by the generated inbound rule, the destination port of the traffic must match this parameter.

TYPE

The TYPE field specifies a value for the Internet Control Message Protocol (ICMP) type. Valid values are an asterisk (*) or in the range 0-255, The default is asterisk (*). This value is only applicable when the PROTOCOL is ICMP. For IP traffic to be permitted by this rule, the ICMP type of the traffic must match this parameter value. If TYPE=*, any ICMP type matches. Also see the CODE field.

IP_STACK: TCP/IP stack configuration

The IP_STACK NEWLIST selects and reports on TCP/IP stack configuration. You can use the following fields to select, exclude, and list data as required. In addition to these fields, each record is uniquely identified by the following fields that are common to all TCP/IP configuration records: COMPLEX, STACK, SYSNAME, SYSPLEX, and SYSTEM. For information about these fields, see "Common fields" on page 1055.

Most of the IP_STACK NEWLIST fields provide information that can be changed with the following commands: IPCONFIG, IPCONFIG6, GLOBALCONFIG, IPSEC, SMFCONFIG, SACONFIG, NETMONITOR, UDPCONFIG, and TCPCONFIG statements.

Field descriptions

The IP_STACK NEWLIST provides the following fields for reporting.

AUDITCONCERN
Indicates the reason for the audit priority. Do not rely on the exact value of this field in your programs. The contents is subject to change.

The following audit concerns can be returned.

Ports below 1024 are not reserved - any user or program can bind to low [TCP|UDP] ports to masquerade as a legitimate service
TCP or UDP ports 1-1023 are no longer reserved for users by the PORT and PORTRANGE statements. As a result, any user or program can bind to low TCP or UDP ports, thus masquerading as a legitimate service.

IPv[4|6] IP filtering support and IPSec tunnel support not active
IPv4 or IPv6 IP filtering support and IPSec tunnel support are not active.

No audit trail of attacks stopped by filter rules
Logging is not enabled for packet filtering.

No audit trail of attacks stopped by default filter rules
Logging is not enabled for packets that are denied by the implicit default rules.

SMF119 *NN* **is not written - audit trail incomplete**
SMF 119 records are not written when any of the following events occur.

- A user initiates the FTP client command (FTPCLIENT).
- Statistics related to LINK utilization become available (IFSTAT).
- A tunnel is added, removed, activated, or deactivated (IPSECURITY).
- Statistics related to reserved PORT utilization become available (PORTSTAT).
- A TCP connection is established (TCPINIT).
- ATCP/IP stack is activated or terminated (TCPIPSTACK).
- TCP/IP statistics become available (TCPIPSTAT).
- A TCP connection is terminated (TCPTERM).
- The TSO Telnet Client code starts or ends a connection (TN3270CLIENT).
- A UDP socket is closed (UDPTERM).

No access control to/from foreign and local networks
Network access control has not been configured.

No access control required to/from foreign networks
Security product access control of user requests is not required for any network not specifically defined by other (non-DEFAULT) NETACCESS statement entries in the TCP/IP stack configuration.

No access control in local network
Security product access control of user requests is not required for any IP address that is local to this stack and that is not specifically defined by other (non-DEFAULTHOME) NETACCESS statement entries in the TCP/IP stack configuration.

By default, anyone can modify TCP/IP security parameters
By default, all users are permitted to issue VARY TCPIP,,OBEYFILE operator commands. This concern can be caused by any of the following conditions:

- The OPERCMDS class is inactive.
- The OPERCMDS resource MVS.VARY.TCPIP.OBEYFILE is not covered by a profile.
- The resource is covered by a profile with UACC or ID(*) (default) access of CONTROL or higher.

Denial-of-service possible without authentication

By default, all users are permitted to issue VARY TCPIP,,DROP, VARY TCPIP,,STRTSTOP, or VARY TCPIP,,SYSPLEX operator commands. This concern can be issued due to any of the following conditions:

- The OPERCMDS class is inactive.
- Any of the following OPERCMDS resources is not covered by a profile: MVS.VARY.TCPIP.DROP, MVS.VARY.TCPIP.STRTSTOP, or MVS.VARY.TCPIP.SYSPLEX.
- Any of the following resources is covered by a profile with UACC or ID(*) (default) access of CONTROL or higher: : MVS.VARY.TCPIP.DROP, MVS.VARY.TCPIP.STRTSTOP, or MVS.VARY.TCPIP.SYSPLEX.

By default, anyone can read netstat [*netstatoption*] output that might help attackers

By default, all users are permitted to read the output of netstat netstatoption commands. They can use this output to obtain network information that can be exploited to mount an attack. The netstatoption value can be any of the following option values: *ALL*, *ALLCONN*, *ARP*, *BYTEINFO*, *CACHINFO*, *CLIENTS*, *CONFIG*, *CONN*, *DEFADDRT*, *DEVLINKS*, *GATE*, *HOME*, *IDS*, *ND*, *PORTLIST*, *RESCACHE*, *ROUTE*, *SLAP*, *SOCKETS*, *SRCIP*, *STATS*, *TELNET*, *TTLS*, *UP*, *VCRT*, *VDPT*, *VIPADCFG*, or *VIPADYN*. If by default, all users are permitted to read the output of all netstat commands, the netstatoption value in the audit concern message is omitted.This concern can be issued due to any of the following conditions:

- The SERVAUTH class is inactive.
- SERVAUTH resource EZB.NETSTAT.systemname.tcpipstackname.netstatoption is not covered by a profile.
- The resource is covered by a profile with UACC or default ID(*) (default) access of *READ* or higher.

The audit concerns are listed in the following table. The audit priorities can be found in 6.2.2.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 364. IP_STACK NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

DATETIME_STARTED

The DATETIME_STARTED field provides the date and time that the TCP/IP stack was started. The format of this field is DATETIME.

DSNMEM

A repeated field that contains a profile information entry for each data set name followed by a member name between brackets [membername] member between brackets). The data set name entries can originate from the following sources: an `OBEYFILE` command, the default library found in the standard search sequence, or an `INCLUDE` statement.

DYNAMICXCF_INTFID

Specifies the interface ID which is used to form the link-local address for the interface. If this field is missing, TCP/IP generates a random value to be used to form the link-local address. The field value can be changed through the use of `IPCONFIG6` statements.

DYNAMICXCF_IP

Contains the IP address to be used as the home address for all dynamically generated XCF, Same Host, and HiperSockets links. The field value can be changed through the use of `IPCONFIG` statements.

DYNAMICXCF_IPMASK

Specifies the interface-level subnet mask for the `DYNAMICXCF` link. If using `OMPROUTE`, this value is overridden with a corresponding `OMPROUTE` interface parameter value that can be coded or set to the default value. The field value can be changed through the use of `IPCONFIG` statements. If the destination address is IPv6, the `DYNAMICXCF_IPMASK` field is missing.

DYNAMICXCF_IP6

Specifies the fully qualified IPv6 address that is used for all dynamically generated XCF, Same Host, and HiperSockets interfaces. The field value can be changed through the use of `IPCONFIG6` statements.

DYNAMICXCF_PFXLEN

Specifies the number of leftmost significant bits for the address mask. The field value can be changed through the use of `IPCONFIG` statements.

DYNAMICXCF_PFXLEN6

Specifies the length of the routing prefix. If this field is not missing and if `DYNAMICXCF` generates a HiperSockets interface definition, TCP/IP creates a

prefix route over the HiperSockets interface using the number of bits specified in DYNAMICXCF_PFXLEN6 field of the DYNAMICXCF_ADDRESS6 field. Therefore, you can configure other stacks outside the sysplex for the same IQD CHPID using IP addresses with the same prefix. This configuration automatically provides this stack with a route to the other stacks over the HiperSockets interface generated by DYNAMICXCF. If DYNAMICXCF_PFXLEN6 is missing, then TCP/IP does not create a prefix route over the HiperSockets interface. For interfaces other than HiperSockets which are generated from DYNAMICXCF, the DYNAMICXCF_PFXLEN6 value has no meaning. The field value can be changed through the use of IPCONFIG6 statements.

DYNAMICXCF_SECCLASS

Specifies the security class for IP filtering associated with each dynamic XCF interface. In order for traffic over the interface to match a filter rule, the filter rule must have the same security class value as the interface or a value of *0*. The value is used only when IPSECURITY is one of the values of the IPCONFIG field. Valid security classes are integers in the range 1 - 255. The default value is 255. The field value can be changed through the use of IPCONFIG statements.

DYNAMICXCF_SECCLASS6

Specifies the security class for IP filtering with each IPv6 dynamic XCF interface. In order for traffic over the interface to match a filter rule, the filter rule must have the same security class value as the interface or a value of 0. This value is used only when IPSECURITY is one of the values of the IPCONFIG6 field. Valid security classes are integers in the range 1 - 255. The default value is 255. The field value can be changed through the use of IPCONFIG6 statements.

DYNAMICXCF_SOURCEVIPAINT

Specifies the name of the static VIPA interface used as the source IP address when SOURCEVIPA is one of the IPCONFIG6 values and outbound packets are sent over the dynamically generated XCF or Same Host interfaces.

GLOBALCONF_IQDVLAN

Returns the VLAN ID which is used when HiperSockets (iQDIO) connectivity is used for dynamic XCF support. Valid VLAN IDs are integers in the range 1 - 4094. They are used to partition communication across HiperSockets. Stacks on the same CPC using the same HiperSockets CHPID that use the same VLAN ID can establish communications. Stacks on the same CPC using the same HiperSockets CHPID that use different VLAN IDs cannot. The field value can be changed through the use of GLOBALCONFIG statements.

GLOBALCONF_MLSCHECKTERM

Flag field that indicates whether the stack should be terminated after writing an informational message when inconsistent configuration information is discovered in a multilevel-secure environment. The field value can be changed through the use of GLOBALCONFIG statements.

GLOBALCONF_XCFGRPID

Provides a group ID value *tt* which is needed only if you want to use subplexing. If the field is not empty, *tt* is a two-digit suffix that is used in generating the XCF group name that the TCP/IP stack joins. The group name is EZBT*vvtt*, where the *vv* value is the VTAM XCF group ID suffix specified with the XCFGRPID VTAM start option.

If no VTAM XCF group ID suffix was specified, the group name is EZBTCP*tt*.

If no VTAM XCF group ID suffix is specified and GLOBALCONF_XCFGRPID is missing, the group name is EZBTCPCS.

These characters are also used as a suffix for the EZBDVIPA and EZBEPORT structure names, in the form EZBDVIPA*vvtt* and EZBEPORT*vvtt*. If no VTAM XCF group ID suffix was specified, the structure names are EZBDVIPA01*tt* and EZBEPORT01*tt*. If the GLOBALCONF_XCFGRPID field is missing, the XCF group name is EZBT*vv*CS and the structure names are EZBDVIPA*vv* and EZBEPORT*vv*. If no VTAM XCF group ID suffix was specified, the group name is EZBTCPCS and the structure names are EZBDVIPA and EZBEPORT. The field value can be changed through the use of GLOBALCONFIG statements.

IPCONFIG

The IPCONFIG field is a repeated flag field that provides information about IPCONFIG parameters. The field value can be changed through the use of IPCONFIG statements. The field can have the following values:

CLAWUSEDOUBLENOP
Channel programs for CLAW devices are forced to have two NOP CCWs to end the channel programs. It is required for some vendor devices, and applies to only first-level MVS systems.

DATAGRAMFWD NOFWDMULTIPATH
The transfer of data between networks is enabled. When transferring data between networks, if there are multiple equal-cost paths to a destination, TCP/IP uses the first active route found for forwarding each IP packet.

DATAGRAMFWD FWDMULTIPATH PERPACKET
The transfer of data between networks is enabled. In transferring data between networks, if there are multiple equal-cost routes to a destination network or host, TCP/IP, upon forwarding an IP packet to a given host in that destination network, selects a route on an approximate round-robin basis from a multipath routing list to that destination host. The selected route is used for routing that IP packet. Connection or connectionless oriented IP packets using the same destination address do not always use the same route, but they do use all possible active routes to that destination host. All IP packets for a given association with a destination host are spread across the multiple equal-cost routes.

NODATAGRAMFWD
The transfer of data between networks has been stopped by disabling IP datagram routing between different network interfaces. Forwarding is disabled.

DYNAMICXCF
Dynamic XCF support is enabled.

NODYNAMICXCF XCF
Dynamic support is not enabled.

FORMAT LONG
For stacks which are not enabled for IPv6, the command output is displayed as if it could contain IPv6 addresses. If the stack is enabled for IPv6, then the presence or absence of this value does not make any difference to the command format. FORMAT SHORT For stacks which are not enabled for IPv6, command output is displayed as if it could contain only IPv4 addresses and not the longer IPv6 addresses. If the stack is enabled for IPv6, this value is not present. This does not make any difference to the command format.

IGNOREREDIRECT
The IGNOREREDIRECT parameter was used in an IPCONFIG statement, or you are using OMPROUTE, or you are using Intrusion Detection Services (IDS) policy to detect and discard ICMP Redirects. As a result, TCP/IP ignores ICMP Redirect packets. IPSECURITY IPv4 IP filtering and IPv4 IPSec tunnel support are activated.

IQDIOROUTING
Inbound packets that are to be forwarded by the TCP/IP stack are eligible to be routed directly between a HiperSockets device and an OSA-Express device in QDIO mode without needing to be sent to this TCP/IP stack for forwarding. This type of routing over a HiperSockets device (iQDIO) is called HiperSockets Accelerator. If specified, HiperSockets Accelerator routes are created dynamically as this TCP/IP stack learns of destination IP addresses that can be routed to or from HiperSockets links without needing to be forwarded to this TCP/IP stack.

NOIQDIOROUTING
Inbound packets that are to be forwarded by this TCP/IP stack are not routed directly between a HiperSockets device and an OSA-Express device in QDIO mode. These packets are processed and routed by this TCP/IP stack.

MULTIPATH PERCONNECTION
The multipath routing selection algorithm for outbound IP traffic is enabled. In general, multipath routing provides the routing distribution necessary to balance the network utilization of outbound packets by load splitting. Multipath routing requires multiple equal-cost routes that are either defined statically or added dynamically by routing protocols (except for RIP, which does not provide multipath routing). The MULTIPATH parameter has no effect if there are no multipath routes in the TCP/IP configuration.

MULTIPATH PERPACKET
Connection or connectionless oriented IP packets using the same source and destination address pair do not always use the same route, but do use all possible active routes to that destination host.

NOMULTIPATH
The multipath routing selection algorithm for outbound IP traffic is disabled. If there are multiple equal-cost routes to a destination, TCP/IP uses the first active route found to send each IP packet.

PATHMTUDISCOVERY
TCP/IP is to dynamically discover the PMTU, which is the smallest MTU of all the hops in the path. This is used to prevent fragmentation of datagrams.

NOPATHMTUDISCOVERY
TCP/IP is not to provide path MTU (PMTU) discovery support.

SOURCEVIPA
TCP/IP is to use the address present in the TCPSTACKSOURCEVIPA field (if that field is not missing) or the corresponding virtual IP address in the HOME list as the source IP address for outbound datagrams that do not have an explicit source address. If the outgoing interface was defined with the INTERFACE statement, TCP/IP uses the VIPA specified on the SOURCEVIPAINTERFACE parameter of the INTERFACE statement instead of the HOME list.

NOSOURCEVIPA
TCP/IP is not to use the corresponding virtual IP address in the HOME list as the source IP address for outbound datagrams.

STOPONCLAWERROR
Channel programs (HALTIO and HALTSIO) are stopped when a device error is detected.

SYSPLEXROUTING
The TCP/IP host is part of an MVS sysplex domain.

NOSYSPLEXROUTING
The TCP/IP host is not part of an MVS sysplex domain.

QDIOACCELERATOR
Inbound packets that are to be forwarded by this TCP/IP stack are eligible to be routed directly between any of the following combinations of interface types:

- A HiperSockets interface and an OSA-Express QDIO interface
- Two OSA-Express QDIO interfaces
- Two HiperSockets interfaces

These packets do not need to be sent to this TCP/IP stack for forwarding. This processing behavior also applies to packets that are forwarded by the Sysplex Distributor. This type of routing is called QDIO Accelerator.

NOQDIOACCELERATOR
Inbound packets that are to be forwarded by this TCP/IP stack are not routed directly between any of the following combinations of interface types:

- A HiperSockets interface and an OSA-Express QDIO interface.
- Two OSA-Express QDIO interfaces.
- Two HiperSockets interfaces

These packets are processed and routed by this TCP/IP stack.

IPCONFIG6

A repeated flag field that provides information on the current settings for `IPCONFIG6` configuration options. Field value for these configuration setting can be changed through the use of `IPCONFIG6` statements. Information on the following configuration settings can be included in this field.

DATAGRAMFWD NOFWDMULTIPATH
The transfer of data between networks is enabled. When transferring data between networks, if there are multiple equal-cost paths to a destination, TCP/IP uses the first active route found for forwarding each IP packet.

DATAGRAMFWD FWDMULTIPATH PERPACKET
The transfer of data between networks is enabled. In transferring data between networks, if there are multiple equal-cost routes to a destination network or host, TCP/IP, upon forwarding an IP packet to a given host in that destination network, selects a route on an approximate round-robin basis from a multipath routing list to that destination host. The selected route is used for routing that IP packet. Connection or connectionless oriented IP packets using the same destination address do not always use the same route, but they do use all possible active routes to that destination host. All IP packets for a given association with a destination host are spread across the multiple equal-cost routes.

NODATAGRAMFWD
The transfer of data between networks has been stopped by disabling IP datagram routing between different network interfaces. If the TCP/IP stack is also configured to be a sysplex distributor, datagrams destined to a sysplex-distributed dynamic VIPA are forwarded to stacks, whether or not forwarding is enabled.

DYNAMICXCF
Dynamic XCF support is enabled for IPv6.

NODYNAMICXCF
Dynamic XCF support is not enabled for IPv6 on this TCP/IP.

IGNOREREDIRECT
The `IGNOREREDIRECT` parameter was used in an `IPCONFIG6` statement, or you are using `OMPROUTE`. TCP/IP ignores ICMPv6 Redirect packets.

IGNOREREDIRECT
The `IGNOREREDIRECT` parameter was used in an `IPCONFIG6` statement, or you are using `OMPROUTE`. TCP/IP ignores ICMPv6 Redirect packets.

IGNOREROUTERHOPLIMIT
TCP/IP ignores any hop limit value received in a router advertisement from a router. The global hop limit value (configured with the `IPCONFIG6 HOPLIMIT` statement) is not overridden by the router advertisement value for all routes using the interface on which the router advertisement was received.

NOIGNOREROUTERHOPLIMIT
TCP/IP does not ignore a hop limit value received in a router advertisement from a router. This results in the configured global hop limit value being overridden by the router advertisement value for all routes using the interface on which the router advertisement was received.

IPSECURITY
IPv6 IP filtering and IPv6 IPSec tunnel support are activated.

MULTIPATH PERCONNECTION
The multipath routing selection algorithm for outbound IP traffic is enabled. In general, multipath routing provides the routing distribution necessary to balance the network utilization of outbound packets by load splitting. Multipath routing requires multiple equal-cost routes that are either defined statically or added dynamically by routing protocols (except for RIP, which does not provide multipath routing). The `MULTIPATH` parameter has no effect if there are no multipath routes in the TCP/IP configuration.

MULTIPATH PERCONNECTION
The multipath routing selection algorithm for outbound IP traffic is enabled. In general, multipath routing provides the routing distribution necessary to balance the network utilization of outbound packets by load splitting. Multipath routing requires multiple equal-cost routes that are either defined statically or added dynamically by routing protocols (except for RIP, which does not provide multipath routing). The `MULTIPATH` parameter has no effect if there are no multipath routes in the TCP/IP configuration.

MULTIPATH PERCONNECTION
The multipath routing selection algorithm for outbound IP traffic is enabled. In general, multipath routing provides the routing distribution necessary to balance the network utilization of outbound packets by load splitting. Multipath routing requires multiple equal-cost routes that are either defined statically or added dynamically by routing protocols (except for RIP, which

does not provide multipath routing). The MULTIPATH parameter has no effect if there are no multipath routes in the TCP/IP configuration.

MULTIPATH PERPACKET
Connection or connectionless oriented IP packets using the same source and destination address pair do not always use the same route, but do use all possible active routes to that destination host. This field indicates that the selected route is used for routing that IP packet. Connection or connectionless oriented IP packets using the same source and destination address pair do not always use the same route, but do use all possible active routes to that destination host. All IP packets for a given association with a destination host are spread across the multiple equal-cost routes.

NOMULTIPATH
The multipath routing selection algorithm for outbound IP traffic is disabled. If there are multiple equal-cost routes to a destination, TCP/IP uses the first active route found to send each IP packet.

SOURCEVIPA
TCP/IP is to use a virtual IP address assigned to the IP_TCPSTACKSOURCEVIPA interface (if IP_TCPSTACKSOURCEVIPA is specified) or to the SOURCEVIPAINTERFACE interface as the source address for outbound datagrams that do not have an explicit source address. If multiple addresses are assigned to the IP_TCPSTACKSOURCEVIPA interface or the SOURCEVIPAINTERFACE interface, the source address is selected from among these addresses according to the default source address selection algorithm.

SOURCEVIPA
TCP/IP is to use a virtual IP address assigned to the IP_TCPSTACKSOURCEVIPA interface (if IP_TCPSTACKSOURCEVIPA is specified) or to the SOURCEVIPAINTERFACE interface as the source address for outbound datagrams that do not have an explicit source address. If multiple addresses are assigned to the IP_TCPSTACKSOURCEVIPA interface or the SOURCEVIPAINTERFACE interface, the source address is selected from among these addresses according to the default source address selection algorithm.

NOSOURCEVIPA
TCP/IP is not to use a VIPA address as the source IP address for outbound datagrams.

TEMPADDRS
TCP/IP is to generate IPv6 temporary addresses for PAQENET6 OSA-Express QDIO interfaces for which stateless address autoconfiguration is enabled.

NOTEMPADDRS
TCP/IP should not generate IPv6 temporary addresses.

IPCONFIG_IPSECURITY

Flag field that indicates whether IPv4 IP filtering and IPv4 IPSec tunnel support have been activated. The field value can be changed through the use of IPCONFIG statements.

IPCONFIG6_IPSECURITY

Flag field that indicates whether IPv6 IP filtering and IPv6 IPSec tunnel support have been activated. The field value can be changed through the use of IPCONFIG6 statements.

IPSEC_DVIPSEC

Flag field that indicates whether IPsec tunnels associated with IPv4 dynamic VIPA addresses are eligible to be distributed if the dynamic VIPA address is being distributed. The IPsec tunnels are also eligible to be moved during dynamic VIPA takeover or giveback. The field value can be changed through the use of IPSEC statements.

IPSEC_LOGENABLE

Flag field that indicates whether logging is enabled for packet filtering. If IPSEC_LOGENABLE is true, then the following log messages might also be written to the syslog by the Traffic Regulation Manager Daemon (TRMD): EZD0814I, EZD0815I, EZD0821I, EZD0832I, EZD0833I, EZD0836I, and EZD0822I. The log setting on the individual default filter rules and the implicit default rules is honored. The field value can be changed through the use of IPSEC statements.

IPSEC_LOGIMPLICIT

Flag field that indicates whether packet filter logging is enabled for packets that are denied by the implicit default rules. IP traffic not explicitly permitted by the default IP filter rules parameters is handled by implicit default rules generated by the stack as long as the default IP filter policy is in effect. A setting of LOGIMPLICIT is honored only when filter logging is enabled on the IPSEC statement with LOGENABLE. The field value can be changed through the use of IPSEC statements.

LAST_CHANGE_DATETIME

Provides the date and time that the TCP/IP stack was last changed. The format of this field is DATETIME.

NETMON_PKTTRCSERVICE

Flag field that indicates whether the real-time TCP/IP packet trace service (SYSTCPDA) is enabled to run on the TCP/IP stack. This service enables network management applications to access trace data collected for any active packet traces or data traces. The field value can be changed through the use of NETMONITOR statements.

NETMON_SMF_IPSECURITY

Flag field that indicates whether real-time IPSec SMF record support is enabled. The field value can be changed through the use of NETMONITOR statements.

NETMON_SMF_PROFILE

Flag field that indicates whether real-time TCP/IP profile SMF event record support is enabled. The field value can be changed through the use of NETMONITOR statements.

NETMON_SMFSERVICE

Flag field that indicates whether the real-time SMF record information service (SYSCPSM) is enabled to run on the TCP/IP stack. The SMF record information service provides an interface for network management applications to obtain stack information in the form of SMF 119 records. Enabling or disabling this service has no effect on the SMF recording function that is available through separate configuration options on the SMFCONFIG profile statement or the FTP.DATA SMF configuration statements. The field value can be changed through the use of NETMONITOR statements.

NETMON_TCPCONN_MINLIFE

Specifies the minimum connection lifetime, specified in seconds, for connections reported by the TCP connection information server. The server waits for this

period before recording information about new connections. If the connection has closed in the meantime, then the connection is not reported by the TCP connection information server. If the field contains *0*, then all connections are reported. The field value can be changed through the use of NETMONITOR statements.

NETMON_TCPCONNSERVICE

Flag field that indicates whether the real-time TCP connection information service (SYSTCPCN) is enabled to run on the TCP/IP stack. The TCP connection information service provides an interface for network management applications to obtain information about TCP connections on this stack. The field value can be changed through the use of NETMONITOR statements.

SACONFIG_OSASF_PORT

A value between 1 to 65535 which indicates a port number and marks the corresponding TCP/IP instance as a candidate to communicate with OSA/SF to retrieve SNMP management data. The data comes from ATM devices and links. A value of 0 in this field indicates that the corresponding TCP/IP instance is no longer a candidate to communicate with OSA/SF, in the event that the OSA/SF-to-TCP/IP connection is restarted. The field value can be changed through the use of SACONFIGstatements.

SACONFIG_SNMP_PORT

Field specifies the port number which is used in establishing communication with the SNMP agent. For the TCP/IP SNMP subagent to communicate with the z/OS Communications Server SNMP agent, the port number specified must match the port number specified on the -p parameter when the SNMP agent is started.

SACONFIG_SNMP_PWDEFAULT

Flag field indicates whether the community name (or password) used to establish contact with an SNMP agent is public, which is the default. For the TCP/IP SNMP subagent to communicate with the z/OS Communications Server SNMP agent, the community name must match one that is defined in the PW.SRC or SNMPD.CONF data set used by the SNMP agent or specified on the -c parameter when the SNMP agent is started. The field value can be changed through the use of SACONFIG statements.

SMF119_FTPCLIENT

Flag field whether SMF type 119 records of subtype 3 are created when a user invokes the FTP client command. The field value can be changed through the use of SMFCONFIG statements.

SMF119_IFSTAT

Flag field that indicates whether SMF type 119 records of subtype 6 containing statistics related to LINK utilization are created. The field value can be changed through the use of SMFCONFIG statements.

SMF119_IPSECURITY

Flag field indicates whether SMF type 119 records of subtypes 77 and 78 are created when a dynamic tunnel is added and removed. Also, SMF type 119 records of subtypes 79 and 80 are created when a manual tunnel is activated or deactivated. The field value can be changed through the use of SMFCONFIG statements.

SMF119_PORTSTAT

Flag field that indicates whether SMF type 119 records of subtype 7 containing statistics related to reserved PORT utilization are created. The field value can be changed through the use of SMFCONFIG statements.

SMF119_TCPINIT

Flag field indicates whether SMF type 119 records of subtype 1 are created when TCP connections are established. The field value can be changed through the use of SMFCONFIG statements.

SMF119_TCPIPSTACK

Flag field that indicates whether SMF type 119 records of subtype 8 are created when a TCP/IP stack is activated and when it is terminated. The field value can be changed through the use of SMFCONFIG statements.

SMF119_TCPIPSTAT

Flag field indicates whether SMF type 119 records of subtype 5 containing TCP/IP statistics are created. The field value can be changed through the use of SMFCONFIG statements.

SMF119_TCPTERM

Flag field that indicates whether SMF type 119 records of subtype 2 are created when TCP connections are terminated. The field value can be changed through the use of SMFCONFIG statements.

SMF119_TN3270CLIENT

Flag field indicates whether SMF type 119 records of subtype 22 and 23 are created when the TSO Telnet Client code starts or ends a connection. The field value can be changed through the use of SMFCONFIG statements.

SMF119_UDPTERM

Flag field that indicates whether SMF type 119 records of subtype 10 are created when a UDP Socket is closed. The field value can be changed through the use of SMFCONFIG statements.

SYSPLEX_GROUP

Field provides the group name for the sysplex.

TCP_RESTRICTLOWPORTS

Flag field that indicates whether TCP ports 1 to 1023 are reserved for users by the PORT and PORTRANGE statements. In this case, applications that have a dependency on being able to obtain an available TCP port in the 1 - 1023 range without having that port explicitly reserved for its use should be run as APF authorized or superuser. The use of RESTRICTLOWPORTS increases system security. The field value can be changed through the use of TCPCONFIG statements

TCPSTACKSOURCEVIPA

Specifies the IPv4 address used as the source IP address for outbound TCP connections. if SOURCEVIPA is one of the values of the IPCONFIG field. The address must be a static VIPA or an active dynamic VIPA (DVIPA). The field value can be changed through the use of IPCONFIG statements.

TCPSTACKSOURCEVIPA6

Specifies the name of a static VIPA or a dynamic VIPA interface. If SOURCEVIPA is one of the values of the IPCONFIG6 field and if the interface has multiple IP addresses, then the *sourcevipa* address for outbound packets is selected from

among these addresses according to the default source address selection algorithm. The field value can be changed through the use of IPCONFIG6 statements.

UDP_RESTRICTLOWPORTS

Flag field that indicates whether UDP ports 1 to 1023 are reserved for users by the PORT and PORTRANGE statements. In this case, applications that have a dependency on being able to obtain an available UDP port in the 1 - 1023 range without having that port explicitly reserved for its use should be run as APF authorized or superuser. The use of RESTRICTLOWPORTS increases system security. The field value can be changed through the use of UDPCONFIG statements.

IP_VIPA: TCP/IP VIPA configuration

The IP_VIPA NEWLIST selects and reports on the VIPA (Virutal IP Address) configuration data for TCP/IP stacks. You can use the following fields to select, exclude, and list data as required. In addition to these fields, each record is uniquely identified by the following fields that are common to all TCP/IP configuration records: COMPLEX, SYSTEM, STACK, SYSNAME, SYSPLEX, and SYSTEM. For information about these fields, see "Common fields" on page 1055.

You can change the field values in the IP_VIPA NEWLIST using VIPADYNAMIC statements. For more information, see the *z/OS Communications Server: IP Configuration Guide (SC31-8776)* at http://publib.boulder.ibm.com/infocenter/zos/v1r11/topic/com.ibm.zos.r11.halz001/toc.htm.

Field descriptions

The IP_VIPA NEWLIST provides the following fields for reporting.

ACTIVE

Indicates whether the Dynamic Virtual IP address is currently active.

INTERFACE

Contains the name of the IPv6 interface.

IP

The IP field contains the Dynamic Virtual IP address (DVIPA).

IPMASK

The IPMASK field contains the IPv4 subnet mask. If the destination address is in IPV6 format, this field is missing.

OPTIONS

The OPTIONS field provides information on the following configuration settings for the VIPA.

MOVEABLE IMMEDIATE
Indicates if the dynamic VIPA whose address is present in the IP field can be activated on this TCP/IP stack if the DVIPA is not already active elsewhere in the sysplex. If the DVIPA has been activated and the TCP/IP stack where the DVIPA is defined by a VIPADEFINE statement is subsequently activated, the DVIPA is activated immediately on that TCP/IP stack. The TCP connections to this TCP/IP stack are preserved. The MOVEABLE IMMEDIATE parameter is used only for activating the DVIPA when it is not already active in the sysplex. If the DVIPA is active, this parameter is ignored.

MOVEABLE NONDISRUPTIVE
Indicates an immediate, nondisruptive movement of a dynamic VIPA from

one stack to another stack. A dynamic VIPA in the VIPARANGE statement can be moved to another stack when that stack requests ownership of the DVIPA as the stack creates it. This ownership request occurs under the following conditions:

- An application binds to the DVIPA,
- The MODDVIPA utility is used to create the DVIPA through the SIOCSVIPA or SIOCSVIPA6 ioctl.
- The application directly issues the SIOCSVIPA or SIOCSVIPA6 ioctl.

The new owning stack forwards packets for any existing connections to the original stack in order that the existing connections are not disturbed. All new connection requests are directed to the new owning stack.

CPCSCOPE
Indicates that the dynamic VIPA whose address is present in the IP field is specific to the central processor complex (CPC) on which it is defined. The VIPA is not moved to or taken over by another TCP/IP stack that is in a different CPC. A DVIPA defined with this characteristic can be used as the default route for incoming requests from Tier 1 targets on this CPC. The Tier 1 target addresses must be on the same subnet as that determined by the address mask value present in theIPMASK field.

TIER1
Indicates that the dynamic VIPA whose address is present in the IP field distributes incoming requests to non-z/OS targets like DataPower appliances or Linux hosts running on system Z.

TIER2
The TIER2 field indicates that the dynamic VIPA whose address is present in the IP field distributes incoming requests from Tier 1 targets to the group of server applications that is named.

SERVICEMGR
Indicates that sysplex distributor performs Multinode Load Balancing (MNLB) by functioning as a Service Manager in place of the Cisco LocalDirector. For these distributed dynamic VIPAs, the SERVICEMGR has no effect if a VIPADISTRIBUTE DEFINE statement does not exist for the dynamic VIPA or VIPAs. SERVICEMGR is optional and can be specified on a VIPABACKUP statement only when MOVEABLE is also specified. This parameter is only for activating the DVIPA when it is not already active in the sysplex. If the DVIPA is active when the VIPABACKUP statement is processed, this parameter is ignored.

PFXLEN

The PFXLEN field contains the prefix length of the subnet address.

RACF_ACL

This repeated field can be used to display the access and conditional access lists of a profile. It can only be used for output on the SORTLIST, DISPLAY, and (D)SUMMARY commands. The display contains userid, access, ACL id, conditional class, and the conditional profile name. The default output length is 45 characters, but the profile name can be 255 characters so the maximum output length is 290 characters.

Use the EXPLODE output modifier for a complete access list that includes access per user through each connect group. Use the RESOLVE output modifier for a resolved access list showing the highest access of each user or group. Use the EFFECTIVE output modifier to extend the resolved access list into the

effective one, which also includes access due to operations or group operations. Be aware that connect information is needed for RESOLVE, EFFECTIVE and EXPLODE, so it works best if specified in the scope of a NEWLIST, while there are no outer selections or with the UNIVERSAL modifier specified to force collection of all relevant data. The SCOPE modifier can be used to extend the modifiers EXPLODE, RESOLVE, and EFFECTIVE with administrative access. To print the ids, the access levels, or both, the ACLACCESS, ACLID and ACLIDACCESS formats can be used. See "Format names for input and output" on page 810.

RACF_PROFILE

Identifies the profile that protects the resource name identified in the RESOURCE field. The profile is programmatically derived using the current RACF database and RESOURCE as inputs.

RANK

Specifies the intended order of the Virtual IP addresses in the VIPABACKUP statement. The VIPAs are listed in their respective backup chains, relative to other stacks in those backup chains. Larger numerical rank values move the respective stacks closer to the beginning of the backup chain. Lower values indicate a position nearer to the end of the backup chain, while higher values indicate a position nearer to the beginning of the chain.

RESNAME

Contains the last qualifier of the SAF SERVAUTH resource name found in the RESOURCE field.

RESOURCE

Identifies the name of an SAF SERVAUTH resource. The resource name has the following format: EZB.MODDVIPA.*sysname.tcpname.resname*. The variable identifiers have the following meanings:

sysname is the value of the MVS &SYSNAME. system symbol. The value comes from the SYSNAME field.

tcpname is the name of the procedure used to start the TCP/IP stack. The value comes from the STACK field.

resname is the 8-character value following the SAF keyword in a SAFNAME statement. The value comes from the RESNAME field.

TYPE

Identifies the Dynamic Virtual IP address (DVIPA) entry type. This field can have the following type values:

VIPABACKUP
Designates one or more dynamic VIPAs for which this stack provides automatic backup.

VIPADEFINE
Designates one or more dynamic VIPAs that this stack should initially own and support. Other stacks can provide backup for these VIPAs if this stack fails.

VIPARANGE
Specifies whether a subnet for which dynamic VIPA activation requests are honored through a BIND, SIOCSVIPA IOCTL, or SIOCSVIPA6 IOCT operation is to be defined or deleted. The value can be *DEFINE* or *DELETE*.

JOBCLASS: JES2 Job Classes

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The JOBCLASS NEWLIST (NEWLIST TYPE=JOBCLASS) describes the job classes per MVS JES2 subsystem. each entry in this NEWLIST can be uniquely identified by the fields SYSTEM SUBSYSTEM CLASS.

Field descriptions

The JOBCLASS NEWLIST provides the following fields for reporting.

ACCT

Flag field that describes whether an account number is required on a JCL JOB statement for the current jobclass. If set (ACCT=YES), the account number is required.

AUDITCONCERN, CONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field. The audit concerns currently defined are listed in the following table. The AUDITCONCERN field can contain one or more concerns separated by commas.

The following audit concerns have been defined regarding Bypass Label Processing:

- BLP left to non-RACF security product

  BLP is allowed for the job class, and a security product other than RACF is active. Security zSecure does not check the BLP protection.
- BLP allowed; TAPEVOL not active, will not test ICHBLP

  BLP is allowed for the job class, but the RACF TAPEVOL class is not active. BLP is not RACF-protected. Whether the FACILITY ICHBLP resource is protected or not is irrelevant, it is not checked.
- BLP allowed; FACILITY not active

  BLP is allowed for the job class, and the RACF TAPEVOL class is active, but the RACF FACILITY class is not active. BLP is not RACF-protected.
- BLP allowed; no ICHBLP profile

  BLP is active, and the RACF TAPEVOL and FACILITY classes are active. However, no ICHBLP profile or any generic profile matching the ICHBLP resource name was defined. BLP is not RACF-protected.
- BLP allowed; UACC of ICHBLP >= UPDATE

  BLP is RACF-protected, but the UACC of the profile used is UPDATE or higher; the RACF-protection is inadequate, since most users are able to use BLP to update tapes.
- BLP allowed for input; UACC of ICHBLP >= READ

  BLP is RACF-protected, but the UACC of the profile used is READ or higher; the RACF-protection is inadequate, since most users are able to use BLP to read tapes.
- BLP RACF-protected

  BLP is RACF-protected. Security zSecure has not detected any audit concerns; the access list of the ICHBLP profile must still be checked.

The following audit concerns have been defined regarding embedded MVS commands:

– MVS Display commands allowed

  Informational MVS commands are allowed in the job class.

– MVS Modify commands allowed

  MVS console, system, or I/O commands are allowed in the job class.

These messages might be followed by one of the following:

– RACF-protected

  RACF is configured to protect the MVS commands by using profiles in the OPERCMDS class. Although there are no catchall profiles (a profile with key=*.**, key=* or key=**) defined, the default RC for this class denies access.

– RACF-protected with UACC=*access*

  RACF is configured to protect the MVS commands by using profiles in the OPERCMDS class. A catchall profile (a profile with key=*.**, key=* or key=**) exists with a UACC that provides the indicated access. The higher the access level, the higher the severity of this concern.

– RACF-protected but low OPERCMDS default RC

  RACF is configured to protect the MVS commands by using profiles in the OPERCMDS class. However, no catchall profile (a profile with key=*.**, key=* or key=**) for this class is defined, and the default RC is too low, possibly allowing access.

– not RACF-protected

  The MVS commands are not protected by RACF. The OPERCMDS class is not active or not defined in de class descriptor table.

Furthermore, these messages are followed by a verify statement:

– verified by operator

  The MVS commands are verified by the operator before being executed.

– not verified by operator

  The MVS commands are not verified by the operator before being executed. (The commands might be displayed on the console.)

Three low-priority audit concerns have been defined:

– No SMF 6

  No SMF type 6 records are written for the job class.

– No SMF 26

  No SMF type 26 records are written for the job class.

– No account numbers required

  The job class does not require account numbers.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 365. JOBCLASS NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.

Table 365. JOBCLASS NEWLIST: Audit priority values and descriptions (continued)

Priority	Meaning
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

AUTH

This field describes the AUTH parameter of the job class, which specifies the MVS command groups to be executed. The AUTH field is a text field, not a symbolic field. This value can be one or more of these text strings: SYS, IO, CONS, and INFO. If all values are set, the text string has the value ALL.

When searching for a particular value other than ALL, for example, IO, include the ALL value in your query. For example, to search for all job classes with an AUTH value including IO, specify:

```
SELECT AUTH=(:IO,ALL)
```

This example selects all AUTH values that match the string ALL or that include the string IO.

Note: When JES2 3.1.3 or later with RACF 1.9 or later is active, the AUTH parameter is ignored.

Table 366. AUTH values and descriptions

AUTH value	Meaning
ALL	All command types
CONS	Console commands
INFO	Information commands
IO	Input/output commands
MASTER	Master console
SYS	System commands

BLP

This flag field describes the Bypass Label Processing parameter of the current jobclass. If set (BLP=YES), bypass label processing is performed subject to SAF (System Authorization Facility) controls; if not set (BLP=NO), the bypass label parameter in the label field of a DD parameter will be ignored, independently of SAF controls.

CLASS

This field describes the class name (a single character).

When combined with the SUBSYSTEM and SYSTEM fields, the CLASS field uniquely identifies an entry in this NEWLIST type.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMMAND

This field describes the jobclass' command disposition parameter, which determines the action taken for MVS commands received imbedded in JCL. This field can have the following values:

Table 367. COMMAND field values and descriptions

Command value	Meaning
DISPLAY	Display the command on the console and execute it without verification.
EXECUTE	Execute the command without display or verification.
IGNORE	Silently ignore the command.
VERIFY	Have the command verified by the operator.

COMPLEX

The security complex that contains the system. The complex name can come from the ALLOC COMPLEX parameter or default to a system name.

HOLD

This flag field describes whether jobs in this jobclass are to be held until the operator issues a RELEASE. If set (HOLD=YES), the job is held until released.

IEFUJP

This flag field describes whether the IEFUJP exit is taken when a job is purged. If set (IEFUJP=YES), the exit is taken.

IEFUSO

This flag field describes whether the IEFUSO exit is taken when a job reaches its SYSOUT output limit. If set (IEFUSO=YES), the exit is taken.

PROCLIB

This field contains the numeric suffix used in defining the PROCLIB DD-name used for this jobclass: PROC*xx*.

REGION

This field describes the default for the region size in this job class. This field has the format **nnnn**K or **nnnn**M, specifying the region size in kilobytes or megabytes.

SUBSYSTEM, SUBSYS

This field describes the subsystem name. For more information on the subsystem, see the NEWLIST TYPE=SUBSYS.

When combined with the SYSTEM and CLASS fields, the SUBSYSTEM field uniquely identifies an entry in this NEWLIST type.

SWA

This field describes whether the SWA (Scheduler Work Area) control blocks for this jobclass are placed above or below the 16 MB line of virtual storage. The value of this field can be ABOVE or BELOW.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. This field length is 8 characters for compatibility with other NEWLIST types.

When combined with the SUBSYSTEM and CLASS fields, the SYSTEM field uniquely identifies an entry in this NEWLIST type.

TIME

This field describes the default for the maximum time that each job step runs. This field has the format *mmmm,ss* or *mmmmmm,ss*, with *mmmm* describing the time in minutes and *ss* describing the time in seconds.

TYPE6

This flag field describes whether SMF record type 6 records (JES2 Output Writer records) are to be written for the current jobclass. If set TYPE6=YES), the records are to be written.

Note: The SMF options and SMF exits determine whether the SMF record is really written. Review the SMF options and Exit reports to see whether this is the case.

TYPE26

This flag field describes whether SMF record type 26 records (JES2 Job Summary records) are to be written for the current jobclass. If set (TYPE26=YES), the records are to be written.

Note: The SMF options and SMF exits determine whether the SMF record is really written. Review the SMF options and Exit reports to see whether this is the case.

MEMBER: Library Change Detection

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The MEMBER NEWLIST (NEWLIST TYPE=MEMBER) describes physical data set members and the changes made to the members over time. There is no simple set of fields that uniquely identifies an entry in this NEWLIST type, because data sets are tracked across multiple systems and volume serials, and multiple versions. In most cases, DATASET VOLSER MEMBER NUMBER is sufficient.

For the sake of convenience, the MEMBER NEWLIST also describes the select few non-partitioned data sets for which checksum information is present in the CKFREEZE file, that is for data sets explicitly specified at CKFREEZE creation. For these data sets, only a limited number of fields in the MEMBER NEWLIST produce meaningful information. In most cases, this should be obvious from the field description. See "Field descriptions."

Field descriptions

The MEMBER NEWLIST provides the following fields for reporting.

AC1

This flag field indicates whether the Authorization Code flag is set to AC=1 or not. It is only available for load modules (LOADMOD=YES). See also the APF field.

ADDITION

This flag field indicates whether the member version is an *addition*, for example a member version was not available in the previous snapshot in which the physical data set was found. It is set for members added to a data set, but also

for a member that reappeared this snapshot after disappearing the previous snapshot, for example rename ONE to TWO and back to ONE). Because the value of this field is based on directory information, it applies only to partitioned data sets.

ALIAS

This flag field indicates whether the member is an alias of another member. Since the value of this field is based on directory information, it applies only to partitioned data sets.

ALIAS_OF

This text field indicates the name of the base member if the current member is an alias. For example, if PROGALIS is an alias of BASE, the ALIAS_OF field in PROGALIS is set to BASE, and the ALIAS_OF field in BASE is blank. It is only available if the ALIAS field is set.

AMODE

This field contains the addressing mode of the load module. It will be **24**, **31**, **64**, or **ANY**. It is only available for load modules (LOADMOD=YES).

APF

This flag field indicates whether the data set is APF-authorized in the most-recent snapshot for each of the systems the data set is found on. A data set is APF-authorized when it appears on the APF list, on the LPA list or on the linklist if it is authorized. If the data set is APF-authorized on at least one system, the APF flag is set.

APPL

This field contains the application owning the load module. It is based on a guess, using a prefix of the member name, and might be wrong in some cases. It is empty if no guess could be made.

BYTES

This field indicates the member size on disk, in kilobytes. It is only available if the CKFREEZE file used was produced with the CHECK=Y orCHECKDSN=*datasetname* parameter specified. For sequential data sets, this field indicates the amount of data contained in the data set, again in kilobytes.

CHECKSUM

This field contains the TEXT checksum on the current member version. It is a 4-byte hexadecimal number (8 characters). The TEXT checksum is a simple checksum based on member contents. It is the same for the same member on any system, independent of the site and CHECKPWD, member name, PDS directory information, ISPF statistics, IDR and ZAP data, etc. It is not very safe against malicious attacks; see the CRC field for a safe checksum. It is only available if the CKFREEZE file used was produced with the CHECK=Y or CHECKDSN=*datasetname* parameter specified.

The main use of the TEXT field is to identify duplicate copies of the member, possibly with another member name or in another data set. The safe CRC checksum, which is dependent on the member name, checksum, etc., cannot be used for this purpose. For sequential data sets, this field can be used to determine whether two entire data sets have identical contents.

COMPLEX

This repeated field describes the security complex that contains the system. This might come from an ALLOC COMPLEX parameter or default to a system name.

CRC

This field contains the CRC checksum on the current member version. It is a 4-byte hexadecimal number (8 characters). The CRC checksum is a digital signature that is safer than the TEXT checksum in that it is very hard for changes to go undetected. In addition, it is different for each site and each CHECKPWD, making it hard for a virus to circumvent the CRC. It is only available if the CKFREEZE file used was produced with the CHECK=Y or CHECKDSN=*datasetname* parameter specified. This field applies to sequential data sets too.

DATASET, DSN

This field describes the data set name.

DELETION

This flag field indicates whether the member version is a *deletion*, for example if a member version is not available in the next snapshot in which the physical data set is found. Because Security zSecure does not report on a member that is not there, the deletion flag is set in the last member version in which the member does appear. It is set for members renamed or deleted from a data set. Since the value of this field is based on directory information, it applies only to partitioned data sets.

DSORG

This field provides an indication of the type of data set. Possible values are PDS, PDSE, PS (indicating normal physical sequential), TAPE, LDS, and ESDS (the last two being VSAM subtypes). Using an overriding output length of less than 4 will result in less distinction, with possible values of PO, PS, and VS only. This field cannot be used on SELECT/EXCLUDE statements.

ENDDATE

This field describes the last snapshot (CKFREEZE) date during which the version was unchanged. For detailed instructions on how to use this field in SELECT/EXCLUDE specifications, see “Date fields” on page 903.

EPA

This field contains the Entry Point offset of the load module. It is only available for load modules (LOADMOD=YES).

IDENTIFY

This repeated field contains the identify data for the member version, in the format '**Date Description**'. It is only available if the CKFREEZE file used was produced with the IDR=YES parameter specified or implied. See also the IDENTIFY_ID and NEW_IDENTIFY fields.

IDENTIFY_ID

This repeated field contains the identify ids for the member version, in the format '**Description**'. It is only available if the CKFREEZE file used was produced with the IDR=YES parameter specified or implied. See also the IDENTIFY and NEW_IDENTIFY fields.

LAST_CHANGE

This field indicates the date and time when the member was last changed or when it was created, whichever is more recent. If the current member version belongs to a PDSE data set and has extended member statistics, this field provides the extended member statistics. Otherwise, this field provides PDF statistics information for the member which includes the PDF_CHGDATE and PDF_CHGTIME, or the PDF_CREADATE, respectively. For information on using this field in SELECT and EXCLUDE operations, "Combined date and time fields" on page 904.

LAST_CHANGE_USERID

This field indicates the user ID that was last used to modify the member. If the current member version belongs to a PDSE data set and has extended member statistics, this field provides the user ID taken from the extended member statistics. Otherwise, this field provides the user ID taken from the PDF statistics for the member. (See "PDF_USERID" on page 1098.)

LKEDDATE

This field describes the date the member was link-edited. It is only available if the CKFREEZE file used was produced with the IDR=YES parameter specified or implied. For detailed instructions on how to use this field in SELECT/EXCLUDE specifications, see "Date fields" on page 903.

LOADMOD

This flag field indicates whether the member is a load module. If set (LOADMOD=YES), the load-module related fields APPL, STORSIZE, EPA, AC1, RENT, REUS, OL, NX, SSI, and AMODE are also available. If not set (LOADMOD=NO), the load-module related fields are left blank.

MEMBER

This field describes the member name.

NEW_IDENTIFY

This repeated field contains the identity data for the member version, in the format '**Date Description**'; unlike the IDENTIFY field, it includes only the IDENTIFY data that was not available in the previous member version. If the current version is 1 (NUMBER=1), this will be empty. It is only available if the CKFREEZE file used was produced with the IDR=YES parameter specified or implied. See also the IDENTIFY and IDENTIFY_ID fields.

NEW_ZAP

This repeated field contains the AMASPZAP IDRDATA for the member version, in the format '**Date Description**'; unlike the ZAP field, it includes only the ZAP data that was not available in the previous member version. If the current version is 1 (NUMBER=1), this will be empty. It is only available if the CKFREEZE file used was produced with the IDR=YES parameter specified or implied. See also the ZAP and ZAP_ID fields.

NUMBER

This field describes the current version number. This number is 1 for the first version found, and is equal to the VERSIONS field for the last version found. The value of this field depends on the CHECK/CHECKDSN parameters that were in effect when the CKFREEZE was created: without CHECK=YES (or at least CHECKDSN for the data sets you want to report about), certain changes might go undetected.

NX

This flag field indicates whether the module is Not Executable. It is only available for load modules (LOADMOD=YES).

OL

This flag field indicates whether the module is Only Loadable. It is only available for load modules (LOADMOD=YES).

PDF

This flag field indicates whether PDF statistics are available for the member. If set (PDF=YES), the related PDF_xx fields are also available. If not set (PDF=NO), the related PDF_xx fields are left blank.

PDF_CHGDATE

If the current member version has PDF statistics, this field describes the date the member was last changed. If no PDF statistics are available, this field is left blank. For detailed instructions on how to use this field in SELECT/EXCLUDE specifications, see "Date fields" on page 903.

PDF_CHGTIME

If the current member version has PDF statistics, this field describes the time the member was last changed, in the format 'HH:MM'. If no PDF statistics are available, this field is left blank.

PDF_CREADATE

If the current member version has PDF statistics, this field describes the date the member was created. If no PDF statistics are available, this field is left blank. For detailed instructions on how to use this field in SELECT/EXCLUDE specifications, see "Date fields" on page 903.

PDF_USERID

If the current member version has PDF statistics, this field describes the user who last modified the member. If no PDF statistics are available, this field is left blank.

PDF_VERSION, PDF_VVMM

If the current member version has PDF statistics, this field describes the version and modification level in the format 'VV.MM'. If no PDF statistics are available, this field is left blank.

PREVDATE

This field describes the previous version's enddate, for example the last snapshot (CKFREEZE) date during which the previous member version was unchanged. It is not available if the NUMBER field is 1. The change occurred in the period PREVDATE to STARTDATE. For detailed instructions on how to use this field in SELECT/EXCLUDE specifications, see "Date fields" on page 903.

PSIGNED

This flag field indicates whether the signed attribute bit is set or not in the library directory entry for the module. This attribute is available only for load modules in a PDSE.

PSIGPROB

This flag field indicates whether or not program signature verification failed for the module. This attribute is available only for load modules in a PDSE.

RENT

This flag field indicates whether the module is re-entrant. It is only available for load modules (LOADMOD=YES).

REUS

This flag field indicates whether the module is serially reusable. It is only available for load modules (LOADMOD=YES).

RMODE

This field contains the residency mode of the load module. It is **24** or **ANY**. It is only available for load modules (LOADMOD=YES).

SCAN_INSTR

This field describes the result of an *instruction scan* performed on the member. It is only available if the CKFREEZE file used was produced with the SCAN=YES parameter and CHECK=Y or CHECKDSN=*datasetname* parameter specified. The instruction scan is performed on the full length of the member, and checks for suspicious instructions in the code.

Note: You should use the contents of this field as a warning, not as a certainty. The instruction scan can cause false alarms and might also be fooled to miss certain instructions. You should always review the source code of suspicious modules.

When used for select/exclude processing, you can use SELECT SCAN_INSTR or SELECT SCAN_INSTR=ANY to select routines in which *any* specified instruction was found; use SELECT SCAN_INSTR=NONE to select routines in which no specified instructions were found. In addition, you can select routines containing any of the specific instructions listed in the following table, for example, SELECT SCAN_INSTR=(FAKEAPF,FAKESPEC).

Because many suspicious instructions can be found within a single module, the default output of this field is in a condensed format; full output split into several lines can be requested using the EXPLODE output modifier and an overriding length of 9, for example SCAN_INSTR(EXPLODE,9). The following table lists the SCAN_INSTR values that can be used for SELECT/EXCLUDE processing; the condensed output; the exploded output; and the meaning.

Table 368. SCAN_INSTR values available for SELECT/EXCLUDE processing

Select/Exclude	Condensed	Exploded	Meaning
BYPASS BYPASSSAF	.B.....	BypassSAF	Request DFP (DFSMS) to bypass SAF calls
FAKEAPF	A.....	FakeAPF	Fake APF/AC(1)-authorization
FAKEOPER	.....O.	FakeOper	Set operations authority
FAKEPRIV	......P	FakePriv	Set privileged/trusted authority
FAKESPEC	....S..	FakeSpec	Set special authority
KEYZERORB	...0...	KeyzeroRB	For an SVC: modify caller's RB to key-zero
MODESUPRB	..M....	ModeSupRB	For an SVC: modify caller's RB to supervisor mode

Note: The values printed by the SCAN_INSTR field are subject to change. Do not write applications that are dependent on the output of this field.

SCAN_STRING

This field describes the result of a *string scan* performed on the member. It is only available if the CKFREEZE file used was produced with the SCAN=YES parameter, SCANSTR arguments, and CHECK=Y or CHECKDSN=*datasetname* parameter specified. The string scan is performed on the full length of the member, and checks for user-specified strings in the code.

By default, zSecure Collect scans load modules for an instruction sequence that is indicative of a published leak. If you have not added another scan string to the Collect run, if the module resides in an APF library and has AC1, and this field returns Yes, then you probably have a big leak in the system.

The value of this field is set to **Yes** if a matching string was encountered in the code; **No** if no string was found; the field is left blank if no string scan was performed.

SCAN_SVC

This repeated field describes the result of an SVC*scan* performed on the member. It is only available if the CKFREEZE file used was produced with the SCAN=YES parameter, SCANSVC list of SVC numbers, and CHECK=Y or CHECKDSN=*datasetname* parameter specified. The SVC scan is performed on the full length of the member, and checks for user-specified SVC calls in the code.

Note: You should use the contents of this field as a warning, not as a certainty. The SVC scan might cause false alarms, and can also be fooled to miss certain SVC calls. You should always review the source code of suspicious modules.

The value of this field has the format '**num: description**' if the SVC scanned for was one of the first seven specified in zSecure Collect; if any of the other SVCs scanned for was encountered, this field has the value '**Other**'.

SEQUENTIAL

This flag field indicates that the data set is not a partitioned data set, but one of the following types of data sets: physical sequential (either tape or DASD), VSAM LDS, or VSAM ESDS.

SMSPLEX, SYSPLEX

This field describes the sysplex name, as specified in SYS1.PARMLIB member COUPLExx.

SSI

This hexadecimal field describes the SSI data. It is only available for load modules (LOADMOD=YES).

STARTDATE

This field describes the first snapshot (CKFREEZE) date during which the version was unchanged. For detailed instructions on how to use this field in SELECT/EXCLUDE specifications, see “Date fields” on page 903.

STORSIZE

This field contains the in-storage size of the load module, in kilobytes. It is only available for load modules (LOADMOD=YES).

SYSTEM

This repeated field describes the systems on which the physical data set was found for this member version.

TTR

This field describes the member TTR, as a 3-byte hexadecimal number (6 characters). For a PDS, this is the track (TT, two bytes) and record number (R, 1 byte) in the data set where the member starts.

VERSIONS

This field describes the number of versions found for the current member. This number will be 1 if the member was unchanged in all observations. To select on members that changed, use SELECT VERSIONS>1. The value of this field depends on the CHECK/CHECKDSN parameters that were in effect when the CKFREEZE was created: without CHECK=YES (or at least CHECKDSN for the data sets you want to report about), certain changes might go undetected. If you read "data set" for all occurrences of "member" in the previous paragraph, the text applies to sequential data sets too.

VOLSER, VOLUME

This field describes the volume serials on which the physical data set was found for this version.

ZAP

This repeated field contains the AMASPZAP IDRDATA for the member version, in the format '**Date Description**'. It is only available if the CKFREEZE file used was produced with the IDR=YES parameter specified or implied. See also the ZAP_ID and NEW_ZAP fields.

ZAP_ID

This repeated field contains the AMASPZAP IDRDATA for the member version, in the format '**Description**'. It is only available if the CKFREEZE file used was produced with the IDR=YES parameter specified or implied. See also the ZAP and NEW_ZAP fields.

MERGE: RACF Database Merge

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•			

The `MERGE NEWLIST (NEWLIST TYPE=MERGE)` provides information about merge processing decisions made during RACF Database Merge operations. This NEWLIST is only available if database merge processing is active. All decisions taken during merge processing are logged, with a reference to the command type, the decision type, the merge phase, and the ids involved. This information provides the data to create reports on the effect of each merge command, pass, and merged profile. No reports have yet been designed.

In this report type, each record describes one decision made, a choice between two default groups for a specific user ID for example. The number of records generated for each profile is dependent on the type of field:

- Fields that describe user/group structure generate one record per user/group and field, even if the value of the field did not change: SUPGROUP, DFLTGRP, OWNER.
- Fields that describe security attributes generate one record per user/group and field, but only if the value of the field changed: SPECIAL, group-SPECIAL, etc.
- All other fields grouped together generate one record per profile.

The MERGE report does not include information about fatal errors during merge processing. These errors are reported through structured error messages.

Field descriptions

The MERGE NEWLIST provides the following fields for reporting.

CLASS, C

This field contains the class name of the profile described by this record. It can be USER, GROUP, DATASET, CONNECT (which is also valid for restructured databases), or a general resource class name, such as TAPEVOL.

CODE

This numeric field returns further information as to why a decision was made. Its meaning depends on the PASS in which the decision was made. Note that several of its values are undocumented here, as these are used for internal bookkeeping and generating error messages. As a consequence, these values will never show up in your reports. The values that can show up are:

Pass 2:	1:	The specified MERGERULE RENAME will be used in further processing.
Pass 3:	1:	The specified MERGERULE SUPGROUP will be used.
	2:	The source superior group is not selected; use the current superior group.
	4:	This group is source-only, and its superior group is not selected. However, the superior group exists on the current system and will be used without modification.
	5:	This group is source-only, so we use its superior group.
	6:	Source and current superior group are identical.
Pass 4:	1:	Use the specified MERGERULE OWNER.
	3:	This profile is current-only; use the current owner.
	5:	Use this group's superior group as the new owner.
	6:	This profile is source-only; use the source owner.
	7:	Source and current owners are the same.
	9:	The owner of this profile has been renamed and will be used as the new owner.
Pass 5:	1:	Use the applicable MERGERULE CONNECT.
Pass 6:	1:	Use the applicable MERGERULE to determine the default group.
	2:	The source default group is not selected; the current one will be used.
	3:	This user is source-only; use the source default group.
	4:	This user is source-only, and the source default group is not selected. The owner will be used as the new default group.
	5:	The source and current default group are identical.
	9:	This user is source-only, its default group is not selected, and the owner cannot be used either. Fortunately, exactly one connect is copied for this user; that group will be used as the default group.
	10:	The default group has been renamed and will be used as the new default group.
Pass 7:	1:	Use the applicable MERGERULE DATA to determine the owner.
	2:	Source and current owners are identical.
	3:	No MERGERULE DATA has been specified. The current owner will be used.
	4:	This profile is source only. The source owner will be used.
	5:	This profile is source-only. The High-level qualifier of the profile will be used as the new owner.
Pass 8:	1:	The appropriate MERGERULE AUTHORITY will be used.

Pass 10:	4:	This AUTHORITY-related field has been set because of a MERGERULE.
	5:	This AUTHORITY-related field has been set because the profile is source-only.

CUR_PROFILE

This field contains the new (current) name of the profile described by this record. It is the same as the original (source) profile name, which is described by the SRC_PROFILE field, unless the profile was renamed. See also the PROFILE field.

CUR_VALUE

This field contains the current value of the field described by this record. See also the SRC_VALUE and NEW_VALUE fields.

FIELD

This field contains the name of the profile field described by this record. It can be a name from the templates or a connect subfield name.

NEW_VALUE

This field contains the new value of the field described by this record, that is, the value that the field should have according to the merge. See also the SRC_VALUE and CUR_VALUE fields.

PASS

This numeric field contains the pass in which the decision was made. It can have a value in the range 2 to 10. The numbers 2 through 9 refer to passes CKRMRG2...CKRMRG9; a short description of their purpose appears in the SYSPRINT. The number 10 corresponds to CKRMRGC, the pass in which the commands are generated.

PROFILE

This field contains the name of the profile described by this record. If the profile is not renamed, it contains a single value. If the profile is renamed, it is a repeated field, containing both the original (source) profile name and the new (current) profile name. See also the SRC_PROFILE and CUR_PROFILE fields.

REASON

This field returns a short description of the reason why a particular decision has been made. Its main purpose is to be of help in pinpointing the cause of unwanted resulting commands.

SRC_PROFILE

This field contains the original (source) name of the profile described by this record. It is the same as the new (current) profile name, which is described by the CUR_PROFILE field, unless the profile was renamed. See also the PROFILE field.

SRC_VALUE

This field contains the original (source) value of the field described by this record. See also the CUR_VALUE and NEW_VALUE fields.

MOUNT: UNIX Mount Points

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The MOUNT NEWLIST (NEWLIST TYPE=MOUNT) describes what file systems are mounted on what mount points. For information about the file system content, see "UNIX: UNIX System Services File System" on page 1480.

Each record in this NEWLIST represents a mount point (on a system). A record can be uniquely identified by the fields SYSTEM, COMPLEX and MOUNTPOINT. An alternate key is SYSTEM, COMPLEX and DEV.

Field descriptions

The MOUNT NEWLIST provides the following fields for reporting.

ACL

Flag field that indicates if the file system supports ACLs. This field can have the following values:

- *Yes* indicates that the file system supports ACLs.
- *No* indicates that the file system does not support ACLs.
- The field is blank if the file system does not recognize ACLs.

In a sysplex environment with some systems that support ACLs and some that do not, files with ACLs are inaccessible from downlevel systems that do not recognize ACL functionality if the FSSEC class is active on an up level system. The files might be accessible by the owner or superuser.

AGGREGATESIZE

The size in blocks of the aggregate. Normally the number of blocks that fit in the primary allocation.

AUDITCONCERN, CONCERN

Indicates the reason for the audit priority. Do not rely on the exact value of this field in your programs. The content of the field is subject to change. The AUDITCONCERN field might contain one or more concerns separated by commas. The following audit concerns have currently been defined:

- Disk scavenging threat / not C2 compliant

  The New Block Security (NBS) option of the ZFS aggregate is inactive. If this option is inactive, it means that if the system crashed while extending or creating a file, and the user data has not yet made it to the disk, the data to be overwritten on disk might be read by anyone who has read access to the extended or newly created file. This situation potentially provides unauthorized users with access to sensitive data in the ZFS. This setting is also a direct violation of the requirements for a C2 rating according to the Orange Book.
- HFS filesystem does not contain security labels

  An HFS file system does not support security labels. If the SETROPTS MLFSOPJ option is activated, the best option is to migrate your file systems to ZFS.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 369. MOUNT NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

BLOCKSIZE

The size of a block of a zFS file system in bytes (normally 8192 bytes).

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

Contains the name of the viewpoint security complex. This value can be specified by the COMPLEX= keyword on an explicit ALLOC statement, or it can default to a system name.

DEV, DEVICE

Contains the device number, which identifies the file system from a viewpoint system.

DSN, DSNAME, DATASET

The MVS data set name of the file system associated with the MOUNTPOINT. This value might not be directly accessible from SYSTEM. See "OWNING_SYSTEM" on page 1106.

FILESYSNAME

The name of the file system. For most file systems, this name is equal to the dataset name.

FILESYSTYPE

Type of file system as specified on the FILESYSTYPE keyword for the BPXPRM*xx* parmlib member. The value is either *HFS* or *TFS* (temporary file system).

FRAGMENTSIZE

Size of a fragment of the zFS file system in bytes. Multiple files can share a logical block if they are smaller than (block size - fragment size), in which case the block gets split up in fragments. The size of a fragment can range from 1024 up to the block size.

MODE

This field indicates how the file system is mounted, read-only or in read/write mode.

MOUNTPOINT

Absolute pathname for the file system root.

NBS

New Block Security. This option only applies to zFS file systems. When enabled, disk blocks are physically cleared before they are linked to a file.

OWNING_COMPLEX

This field contains the name of the security complex of which the system that owns the file system data set associated with the mount point is a part. See also "OWNING_SYSTEM."

OWNING_SYSTEM

Contains the name of the system that owns the file system data set associated with the mount point. The unified file system within a sysplex can be shared. If it is shared, the actual data set can be managed by one system while providing access to all systems even if the systems do not share the DASD.

READONLY_SECLABEL

Contains the security label that is assumed for UNIX file systems (z/OS 1.5 and up) if all of the following conditions are met:

- The security product running on the system is RACF.
- The data set for the file system is protected by a DATASET profile that specifies a security label.
- The file system is mounted read-only.
- The SETROPTS MLFSOBJ option is active when you mount the file system.
- The root directory of the file system does not have a security label.

See also 1460, and "SECLABEL" on page 1489.

RWSHARE

A flag field that indicates whether the zFS read-write file system is sysplex-aware. If the value is Yes, the zFS file system is mounted with SYSPLEX_MODE=on or mounted with PARM(RWSHARE) when SYSPLEX_MODE=filesys. If the value is No, the zFS file system is not sysplex-aware.

SECURITY

Flag field that indicates whether the file system is mounted with the SECURITY option that determines whether security checks are performed. If this option is not active, the setuid, setgid, APF, and program control bits are ignored. For directories, the sticky bit is also ignored if the SECURITYoption is not active.

SERIAL

Describes the volume serial number for the DASD unit and the device ID for the file system data set associated with the mount point. This field might not return a value if the CKFREEZE data sets that have been allocated do not contain a detailed description of both the OWNING_SYSTEM and the SYSTEM. This field can be used to disambiguate between DASD volumes with the same volume serial. See also "BOX_SERIAL field for DASDVOL report" on page 1014 for further details.

SETUID

Flag field that indicates whether the file system is mounted with the SETUID option that determines if the setuid, setgid, APF, and program control bits are

to be honored. The file system must also be mounted with the SECURITY option for these bits to actually be honored. See "SECURITY" on page 1106.

SYSPLEX_MODE

A field that indicates the sysplex status. The possible values are:

- **Noshare**: zFS is not in a shared file system environment.
- **Admin-only**: zFS is in a shared file system environment but is not sysplex-aware.
- **On**: zFS is in a sysplex-aware environment with sysplex=on.
- **Filesys**: zFS is in a sysplex-aware environment with sysplex=filesys.

SYSTEM

The name of the (viewpoint) system. For MVS systems, this value is the SMF system ID. The field length is 8 characters by default for compatibility with other NEWLIST types.

TRUSTED

Flag field that indicates if the file system is mounted as trusted or not. This field indicates if the setuid, setgid, program control and APF authorized bits are honored. It summarizes the SECURITY and SETUID flags.

VOLSER, VOLUME

The first volume serial of the file system data set associated with the mount point. This field might not have a value if the CKFREEZE data sets that are allocated do not contain a detailed description of the OWNING_SYSTEM and the SYSTEM.

MSG: Message Processing Facility

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The MSG NEWLIST (NEWLIST TYPE=MSG) describes the message-specific data of the MVS Message Processing Facility (MPF). Each entry in this NEWLIST can be uniquely identified by the fields SYSTEM MSGID.

Field descriptions

The MSG NEWLIST provides the following fields for reporting.

AUDITCONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field. The AUDITCONCERN field can contain one or more concerns separated by commas. The following audit concerns have currently been defined:

- RACF message suppressed

  RACF is active, and a RACF message is suppressed. Security messages should not be suppressed; if too many such messages occur, they should be routed to a separate console.
- Default messages suppressed

  The default-entry .NOENTRY is suppressed. All messages not explicitly named in the MPF table are suppressed.

- Message automated

  The message is automated. This is not a serious concern, though the automation should be reviewed.
- Message suppressed

  The message is suppressed. This is not a serious concern, though the message id should be checked to see whether the message is sensitive and should not be suppressed.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 370. MSG NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

AUTO

This field indicates the automation setting specified for the message. It is set to NO if the message is not eligible for automation processing and to YES if it is but no automation token was specified. Otherwise it will contain the token that will be passed to the automation subsystem.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. The complex name can come from the ALLOC COMPLEX parameter or default to a system name.

EXIT

This field indicates the module name of a user exit defined for the message. If no user exit is defined, the EXIT field and the derived fields are blank.

EXIT_ADDRESS

This field indicates the address of the user exit defined for the message. See also the EXIT field.

EXIT_AT

This field indicates the load module information for the user exit defined for the message. See also the EXIT field. It contains a short description of the program name, module name, and offset, in the format described in the following table.

Table 371. EXIT_AT format description

EXIT_AT format	Minor/Major EP	Offset zero
Module	Major	Yes
Module+offset	Major	No
Program in Module	Minor	Yes
Program+offset in Module	Minor	No

EXIT_WHERE

A string indicating the virtual storage area where the exit routine resides. Possible EXIT_WHERE values and their meaning are documented in the following table. The areas starting with an E reside above the 16 MB line in virtual storage.

Table 372. EXIT_WHERE values and descriptions

EXIT_WHERE value	Meaning
CSA	Common Storage Area
ECSA	Extended Common Storage Area
EFLPA	Extended Fixed Link Pack Area
EMLPA	Extended Modified Link Pack Area
ENUC RO	Read-only Extended Nucleus Area
ENUC RW	Writable Extended Nucleus Area
EPLPA	Extended Pageable Link Pack Area
EPVT	Extended Private Area
ESQA	Extended System Queue Area
FLPA	Fixed Link Pack Area
MLPA	Modified Link Pack Area
NUC RO	Read-only Nucleus Area
NUC RW	Writable Nucleus Area
PLPA	Pageable Link Pack Area
PSA	Prefix Storage Area
PVT	Private Area
SQA	System Queue Area

MPFLST

The parmlib member name of the member used to set MPF processing.

MSGID

The message id, a string of up to 10 characters. When combined with the SYSTEM field, the MSGID field uniquely identifies an entry in the NEWLIST TYPE=MSG.

SUPPRESS, SUP

This text field indicates whether the message is suppressed. If a message is suppressed (SUPPRESS=YES), the message is not displayed on the MCS console. If SUPPRESS=ALL, not only is the message not displayed, the command responses are suppressed as well.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. The field length is 8 characters for compatibility with other NEWLIST types. When combined with the MSGID field, the SYSTEM field uniquely identifies an entry in the NEWLIST TYPE=MSG.

NEWLIST: Report translation properties

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The NEWLIST TYPE=NEWLIST enumerates the non-suppressed `NEWLIST` statements encountered when a CARLa program is run and lists the original English and default translated properties for each `NEWLIST` type included in the program.

An approximate key for records in this `NEWLIST` type is `NEWLIST_TYPE NEWLIST_NAME SRCEDDN SRCEMEM SRCELINE`, but it is not necessarily unique.

Table 373 list the fields supported by the `NEWLIST TYPE=NEWLIST`.

Table 373. `NEWLIST TYPE=NEWLIST` - available fields.

Field Name	Column Header	Length
"DETAILHELPPANEL" on page 1111	**Det help panel**	8
"HELPPANEL" on page 1111	**Help pnl**	8
"LANGUAGE" on page 1111	**Lng**	3
"NEWLIST_NAME" on page 1111	**Name**	16
"NEWLIST_TYPE" on page 1111	**Type**	24
"SRCEDDN" on page 1111	**DDname**	8
"SRCELINE" on page 1111	**Line**	6
"SRCEMEM " on page 1111	**Member**	8
"SUBTITLE" on page 1111	**Subtitle**	64
"SUBTITLE_ORIG" on page 1111	**Original subtitle**	64
"SUMHELPPANEL" on page 1111	**Sum help panel**	8
"TITLE" on page 1111	**Title**	64
"TITLE_ORIG" on page 1111	**Original title**	64
"TOPTITLE" on page 1111	**Toptitle**	64
"TOPTITLE_ORIG" on page 1111	**Original toptitle**	64

Field descriptions

The NEWLIST NEWLIST provides the following fields for reporting.

DETAILHELPPANEL

The identifier for the help panel associated with the detail panel opened using a DISPLAY command.

HELPPANEL

The identifier for the help panel associated with the overview of panel showing selected records that is opened using a DISPLAY command.

LANGUAGE

The specified translation language for the NEWLIST output. This value is a three-character abbreviation for the language as defined in a LANGUAGE statement.

NEWLIST_NAME

The NAME passed on the NEWLIST statement. This value is optionally suffixed with .DISPLAY if the NEWLIST statement contains a DISPLAY or DSUMMARY statement, as opposed to only a subset of the LIST, SORTLIST, and SUMMARY statements.

NEWLIST_TYPE

The character format for the NEWLIST.

SRCEDDN

The ddname where the NEWLIST statement was encountered.

SRCELINE

The line number where the NEWLIST statement was encountered.

SRCEMEM

The member name where the NEWLIST statement was encountered (if the ddname is not unique).

SUBTITLE

The final subtitle for this NEWLIST.

SUBTITLE_ORIG

The original text for the subtitle. This value has not been translated.

SUMHELPPANEL

The identifier for the help panel associated with the summary level display panel opened using the DISPLAY command.

TITLE

The final title for this NEWLIST If translation is specified, this value represents the translated title.

TITLE_ORIG

The original text for the title. This value has not been translated.

TOPTITLE

The final top-level title for this NEWLIST. If translation is specified, this value represents the translated title.

TOPTITLE_ORIG

The original text for the top-level title. This value has not been translated.

PC: Program Calls

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The PC NEWLIST (NEWLIST TYPE=PC describes program calls that are identified by system-table-entry. Each Program Call entry is a record in this NEWLIST type which means that, for all entries in a table, the table-related information is the same.

Use a SUMMARY command to display the table-related information. Information that is repeated for the table is repeated for each entry in the PC report or listing. One possible example of repeated information is the LX field.

Each entry in this NEWLIST can be uniquely identified by the fields SYSTEM ENTRY EX.

Field descriptions

ADDRESS

Contains the address of the program call routine as 32 bit address. Several program calls can share the same address. Also, a Program Call that does not use space-switching that resides in private storage might execute different code depending on the address space for the caller. Each address space can create its own version in private storage.

ADDRESS64

Contains the address of the program call routine as 64 bit address. Several program calls can share the same address. Also, a Program Call that does not use space-switching that resides in private storage might execute different code depending on the address space for the caller. Each address space can create its own version in private storage. See also "ADDRESS."

AKM

Contains a 4-digit hexadecimal number with the Authorized Key Mask, which is a 16-bit bit field representing the list of PSW keys that the caller can have. The value X'8000' indicates key-0, value X'0001' indicates key-15. The AKM_KEY field lists the individual keys from the AKM.

AKM_KEY

Repeated field that contains the list of PSW keys that the caller can have. Together these keys form the Authorized Key Mask AKM, representing the PSW keys the caller can have. Each key is a decimal number in the range 0 to 15.

AMODE

Contains the addressing mode of the program call routine. The value can be **24**, **31**, or **64**.

ASID

Contains the ID of the address space in which the program call routine executes. If this program call routine is not a space-switching program call

(SPACE_SWITCH=NO), this field is blank, indicating the current address space. The address space ID is a 2 byte hexadecimal number; the JOBNAME field shows the related job name.

AT

Repeated field that contains a short description of the program name, module name, and offset, in the format described in the Table 374. The values are derived from the program-call address.

Table 374. AT format description

AT format	Minor/Major EP	Offset zero
Module	Major	Yes
Module+offset	Major	No
Program in Module	Minor	Yes
Program+offset in Module	Minor	No

AUDITCONCERN

Indicates the reason for the audit priority. Do not rely on the exact value of this field in your program because the content might change. The AUDITCONCERN field can contain one or more concerns separated by commas. The following audit concerns have currently been defined:

- **In caller's private area**

  The Program Call is executed in the private area of the caller, and the Program Call is available in more than one address space. Each address space can execute different code for the Program Call. If the Program Call is available to unauthorized callers, and executes authorized or with additional authorization, any user might be able to subvert the system.
- **Caller may be unauthorized**

  The Program Call is available to non-authorized callers.
- **LPA param in writable storage**

  The Latent Parameter Area contains a value that, if used as a pointer, points to writable common storage. This situation potentially permits all users to alter the parameters to the Program Call.
- **Executes authorized**

  The Program Call executes in authorized state. For BASIC program calls, this configuration is normal.
- **Resides in common storage**

  The Program Call resides in common storage, hence a risk of disassembly.
- **System Entry Table**

  Available to callers in all address spaces.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 375. PC NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.

Table 375. PC NEWLIST: Audit priority values and descriptions (continued)

Priority	Meaning
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

AUTHREQ

Flag field that indicates if authority is required to use the Program Call. That is, if the AKM contains key 8. If set (AUTHREQ=YES), authority is required.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. This value can come from the ALLOC COMPLEX parameter or default to a system name.

CONTENT, CONTENTS

A string containing up to the first 256 bytes of the routine, which usually include the eye catcher. The default output length of this string is 128 characters (containing the first 128 bytes of the program call routine). In the default output format, the readable text from the contents is shown; the non-printable parts of the contents have been replaced by one or two periods (.).

DESCRIPTION, SFT_DESCRIPTION

This character field contains a description of the Program Call. If the program call routine is a system-defined program call routine as indicated by definition of the SFT_INDEX field, this value is a description of the entry in the System Function Table. In other cases, zSecure tries to guess the function using the module name. If a description is found, it is printed in parentheses (SMS) for example, which indicates that the name is a guess and might be incorrect. If the product cannot make a guess about the module name, the field is left blank.

EK

Contains the PSW protection key that the program call routine uses for running the routine if this value is set by the program call.

EKM

Contains a 4-digit hexadecimal number with the Entry Key Mask EKM of the program call routine. The value X'8000' indicates key-0, value X'0001' indicates key-15. Depending on the PKM field, this key mask is ORed with the key mask for the caller (PKM=OR) or replaces the key mask for the caller (PKM=REPLACE). The EKM_KEY field lists the individual keys from the EKM.

EKM_KEY

Repeated field that contains the list of PSW keys that make up the Entry Key Mask EKM of the program call routine. Depending on the PKM field, this key mask is ORed with the key mask for the caller (PKM=OR) or replaces the key mask (PKM=REPLACE).

ENTRY

Contains a number identifying the Entry Table which the program call routine is a part of. When combined with the SYSTEM and EX fields, this value uniquely identifies a program call routine.

This field has the same value for all Program Call routines that are part of the same entry table.

Note: This field is *not* system-defined, it is defined by Security zSecure to distinguish between entry tables.

ET_ASID

Contains the ID of the address space owning the Entry Table.

All Program Call routines that are part of the same entry table have the same value in this field.

ET_CONNECTS

This field contains the number of connections for the Entry Table.

All Program Call routines that are part of the same entry table have the same value in this field.

ET_JOBNAME

This field contains the job name of the address space owning the Entry Table. If no job name can be found, this field has the format '>ASID<', where ASID represents the address space ID.

All program call routines that are part of the same entry table have the same value in this field.

ET_SYSTEM

Flag field that indicates if the Entry Table that the program call routine is a part of is a system table (`ET_SYSTEM=YES`) or not. A system table defines `PC` routines that can be called from any address space.

All Program Call routines that are part of the same entry table have the same value in this field.

EX

Contains the index in the Entry Table that identifies the program call routine. When combined with the SYSTEM and ENTRY fields, this value uniquely identifies a program call routine. The entry index EX is a decimal field of up to three digits.

JOBNAME

Contains the job name of the address space in which the program call routine runs. If this program call routine does not use space-switching (`SPACE_SWITCH=NO`), this field is blank, indicating the current address space. If no job name can be found, this field has the format '*>ASID<*', where `ASID` represents the address space ID.

KEY

This field contains the storage protection key of the Program Call routine, if it resides in CSA, ECSA, SQA, or ESQA.

In current systems, a storage key of 8 or 9 is a serious cause for concern because any user is able to change the Program Call routine. A key of 10 to 15 is a

minor cause for concern: Only users executing in that key are able to change the Program Call routine. Keys 10 to 15 can normally only be used by applications running programs from APF libraries. An exception exists for ADDRSPC=REAL. For additional information see 1451.

LENGTH

Contains the length of the program or module that the Program Call is part of if the residency is in the LPA (EFLPA, EMLPA, EPLPA, FLPA, MLPA, or PLPA). If the CKFREEZE data contains sufficient information, this value can also indicate if the residency is a server address space private area (PVT, EPVT). The length is approximated as the length up to the end of the module, or the length up to the next entry point.

LX

Repeated field that contains the Linkage Index numbers for the Entry Table that identifies the program call routine. It is part of a structured repeat group with information such as address space ID, *dormant flag*, and so on.

All Program Call routines that are part of the same entry table have the same value in this field. MVS tries to keep the LX for each entry table the same across all connected address spaces, but this configuration is not a hardware requirement.

LX_ASID_CNT

Repeated field that contains the number of address space IDs for the current Linkage Index repeat-group entry. This field is part of the structured repeat group described by the LX field.

All program call routines that are part of the same entry table have the same value in this field.

LX_CONN_ASID

This repeated field contains the connected address space ID for the current Linkage Index repeat-group entry. It is part of the structured repeat group described with the LX field. The address space id is a 2-byte hexadecimal number; the LX_CONN_JOBNAME field shows the related job name.

All program call routines that are part of the same entry table have the same value in this field.

LX_CONN_JOBNAME

This repeated field contains the job name of the connected address spaces for the current Linkage Index repeat group entry. It is part of the structured repeat group described with the LX field. If no job name can be found, this field has the format '>ASID<', where ASID represents the connected address space id.

All program call routines that are part of the same entry table have the same value in this field.

LX_DORMANT

This repeated flag field indicates whether the current Linkage Index repeat group entry is dormant. It is part of the structured repeat group described with the LX field.

All Program Call routines that are part of the same entry table have the same value in this field.

LX_OWNR_ASID

Repeated field that contains the owning address space ID for the current Linkage Index repeat group entry. This field is part of the structured repeat group described with the LX field. The address space id is a 2-byte hexadecimal number; the LX_OWNR_JOBNAME field shows the related job name.

All program call routines that are part of the same entry table have the same value in this field.

LX_OWNR_JOBNAME

Repeated field that contains the job name of the owning address spaces for the current Linkage Index repeat group entry. This field is part of the structured repeat group described with the LX field. If no job name can be found, this field has the format '>ASID<', where ASID represents the connected address space ID.

All program call routines that are part of the same entry table have the same value in this field.

LX_SEQNUM

Repeated field that contains the sequence number for the current Linkage Index repeat-group entry. This value is part of the structured repeat group described with the LX field. When it is nonzero, it is used to check whether the PC instruction was indeed intended to call this instance of a reused LX.

All Program Call routines that are part of the same entry table have the same value in this field.

LX_SYSTEM

This repeated flag field indicates whether the current Linkage Index repeat group entry is a system Linkage Index. It is part of the structured repeat group described with the LX field.

All Program Call routines that are part of the same entry table have the same value in this field.

LX_TABLE_CNT

This repeated field contains the number of entry tables for the current Linkage Index repeat group entry. It is part of the structured repeat group described with the LX field.

All Program Call routines that are part of the same entry table have the same value in this field.

MODE_SUP

This flag field indicates whether the program call routine executes in supervisor state (MODE_SUP=YES) or problem-program state (MODE_SUP=NO). When used for output in the default format, it is blank if MODE_SUP=NO. See also the STATE field.

Basic Program Call routines often execute in supervisor state because otherwise the Program Call cannot return to a supervisor mode program. The PR instruction cannot go from problem program mode to supervisor mode. For non-basic Program Call routines, the Program Call must only run in supervisor state if authorized operation is required.

MODULE

Contains the major entry point name of the module in which the Program Call is located, if the residency is in the LPA (EFLPA, EMLPA, EPLPA, FLPA, MLPA,

PLPA). If CKFREEZE contains sufficient information, it can also be filled in if the residency is a server address space private area (PVT, EPVT).

OFFSET

Contains the offset between the entry point for the program and the entry point for the program call, if the residency is in the LPA (EFLPA, EMLPA, EPLPA, FLPA, MLPA, PLPA). If the CKFREEZE data contains sufficient information, the field might also indicate if the residency is a server address space private area (PVT, EPVT). The offset is calculated from the previous entry point, and is zero if the address is located at a minor or major entry point.

PARM_ADDRESS

Contains the address of the latent parameter area for the program call routine. This area, which is typically located in ESQA, can contain one or two user-pointers determined by the creator of the Program Call. See the PARM_xx, PARM1_xx, and PARM2_xx fields.

PARM_KEY

This field contains the storage protection key of the Latent Parameter Area (LPA), if it resides in CSA, ECSA, SQA, or ESQA. A key of 8 to 15 is a cause for concern because any user can potentially change the Latent Parameter Area.

PARM_SUBPOOL

Contains the storage area subpool of the Latent Parameter Area (LPA), if it resides in CSA, ECSA, SQA, or ESQA.

PARM_WHERE

Contains the residency of the Program Call's Latent Parameter Area. See the WHERE field for a reference.

PARM1_ADDRESS

Contains the address of the first user parameter in the Latent Parameter Area (LPA) for the program call routine.

PARM1_AT

Contains the module information of the first user parameter in the LPA. See the AT field for a reference.

PARM1_KEY

Contains the storage protection key of the first user parameter in the Latent Parameter Area (LPA), if it resides in CSA, ECSA, SQA, or ESQA. A key of 8 to 15 might be a cause for concern.

PARM1_SUBPOOL

Contains the storage area subpool of the first user parameter in the Latent Parameter Area (LPA), if it resides in CSA, ECSA, SQA, or ESQA.

PARM1_WHERE

Contains the residency of the first user parameter in the Latent Parameter Area. See the WHERE field for a reference.

PARM2_ADDRESS

Contains the address of the second user parameter in the Latent Parameter Area for the program call routine.

PARM2_AT

Contains the module information of the second user parameter in the LPA. See the AT field for a reference.

PARM2_KEY

Contains the storage protection key of the second user parameter in the Latent Parameter Area (LPA), if it resides in CSA, ECSA, SQA, or ESQA. A key of 8 to 15 might be a cause for concern.

PARM2_SUBPOOL

Contains the storage area subpool of the second user parameter in the Latent Parameter Area (LPA), if it resides in CSA, ECSA, SQA, or ESQA.

PARM2_WHERE

Contains the residency of the second user parameter in the Latent Parameter Area. See the WHERE field for a reference.

PC

Repeated field that describes the PC number, for example LX + EX. This value is the Program Call number as encountered in program code. It is part of the structured repeat group described with the LX field.

This field has the same value for all Program Call routines that are part of the same entry table.

PC_TYPE

Indicates the type of Program Call routine. The value is either `BASIC` or `STACKING`. Stacking routines are the best option.

PKM

Indicates the use made of the execution key mask (EKM). Depending on the value of the PKM field, the key mask for the caller is ORed with the EKM (PKM=OR) or replaced by the EKM (PKM=REPLACE).

PROGRAM

Indicates the 8-character name of the program that is called by the Program Call. This value is not necessarily at offset 0, nor is it necessarily the load module name; it might be a minor entry point name. See field AT for a more accurate (but wider) field that includes any nonzero offset and both major and minor names, if available.

SCAN_INSTR

Describes the result of an *instruction scan* performed on the Program Call code. It is only available if the CKFREEZE file used was produced with the SCAN=YES parameter. The instruction scan is performed on the full length of the Program Call (not just on the eye catcher) and checks for suspicious instructions in the code.

Note: Interpret the contents of this field as a warning, not as a certainty. The instruction scan can cause false alarms, and can also be fooled to miss certain instructions. Always review the source code of suspicious modules.

When used for SELECT or EXCLUDE processing, you can use SELECT SCAN_INSTR or SELECT SCAN_INSTR=ANY to select routines in which *any* specified instruction was found; use SELECT SCAN_INSTR=NONE to select routines in which no specified instructions were found. In addition,

you can select routines containing any of the specific instructions listed in the table Table 376, SELECT SCAN_INSTR=(FAKEAPF,FAKESPEC) for example.

Because many suspicious instructions can be found within a single module, the default output of this field is in a condensed format. Full output can be split into several lines by using the EXPLODE output modifier and an overriding length of 9, SCAN_INSTR(EXPLODE,9) for example. Table 376 lists the SCAN_INSTR values that can be used for SELECT/EXCLUDE processing; the condensed output; the exploded output; and the meaning.

Table 376. SCAN_INSTR values for SELECT and EXCLUDE processing

Select/Exclude	Condensed	Exploded	Meaning
BYPASS BYPASSSAF	.B.....	BypassSAF	Request DFP (DFSMS) to bypass SAF calls
FAKEAPF	A.....	FakeAPF	Fake APF/AC(1)-authorization
FAKEOPER	.....O.	FakeOper	Set operations authority
FAKEPRIV	......P	FakePriv	Set privileged/trusted authority
FAKESPEC	....S..	FakeSpec	Set special authority
KEYZERORB	...0...	KeyzeroRB	For an SVC: modify RB for the caller to key-zero
MODESUPRB	..M....	ModeSupRB	For an SVC: modify RB for the caller to supervisor mode

Note: The values printed by the SCAN_INSTR field are subject to changes in future releases. Do not write applications that are dependent on the output of this field.

SCAN_STRING

Describes the result of a *string scan* performed on the Program Call code. It is only available if the CKFREEZE file used was produced with the SCAN=YES parameter and SCANSTR arguments set. The string scan is performed on the full length of the Program Call not just on the eye catcher. The scan checks for user-specified strings in the code.

The value of this field is set to *Yes* if a matching string was encountered in the code. The value is *NO* if no string was found; the field is left blank if no string scan was performed.

SCAN_SVC

Repeated field that describes the result of an SVC*scan* performed on the Program Call code. It is only available if the `CKFREEZE` file used was produced with the `SCAN=YES` parameter and `SCANSVC` list of SVC numbers set. The SVC scan is performed on the full length of the Program Call not just on the eye catcher. The scan checks for user-specified SVC calls in the code.

Note: Interpret the contents of this field as a warning, not as a certainty. The SVC scan can cause false alarms, and can also be fooled to miss certain SVC calls. Always review the source code of suspicious modules.

The value of this field has the format `num: description` if the SVC scanned for was one of the first seven specified in zSecure Collect. If any of the other SVCs scanned for was encountered, this field has the value *`Other`*.

SFT_INDEX

If the Program Call routine is a system-defined Program Call routine, this field describes the entry number of the routine in the System Function Table. Otherwise, the field is blank. See also the DESCRIPTION field.

SPACE_SWITCH

Flag field that indicates if the Program Call routine is a space-switching call (SPACE_SWITCH=YES) or a local call (SPACE_SWITCH=NO).

STATE

Field that indicates whether the Program Call routine executes in supervisor state (STATE=SUPERVISOR) or problem program state (STATE=PROBLEM). See also the MODE_SUP field.

SUBPOOL

Contains the storage area subpool of the Program Call routine, if the residency is in CSA, ECSA, SQA, or ESQA.

SYSTEM

The name of the system. For MVS systems, this value is equal to the SMF system id. This field is 8-characters long for compatibility with other NEWLIST types.

When combined with the ENTRY and the EX fields, the SYSTEM field uniquely identifies an entry in this NEWLIST type.

WHERE

A string indicating the virtual storage area where the program call routine resides. Table 377 lists the possible WHERE values and their meaning. Areas starting with an E reside above the 16 MB line in virtual storage.

Table 377. PC NEWLIST - WHERE field values

WHERE value	Meaning
CSA	Common Storage Area
ECSA	Extended Common Storage Area
EFLPA	Extended Fixed Link Pack Area
EMLPA	Extended Modified Link Pack Area
ENUC RO	Read-only Extended Nucleus Area
ENUC RW	Writable Extended Nucleus Area
EPLPA	Extended Pageable Link Pack Area
EPVT	Extended Private Area
ESQA	Extended System Queue Area
FLPA	Fixed Link Pack Area
MLPA	Modified Link Pack Area
NUC RO	Read-only Nucleus Area
NUC RW	Writable Nucleus Area
PLPA	Pageable Link Pack Area
PSA	Prefix Storage Area
PVT	Private Area
SQA	System Queue Area

PPT: Program Properties Table

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The PPT NEWLIST (`NEWLIST TYPE=PPT`) describes the MVS Program Properties Table. Each entry in this `NEWLIST` represents one PPT entry, and is uniquely identified by the fields `PROGRAM SYSTEM`.

Field descriptions

The `PPT NEWLIST` provides the following fields for reporting.

AUDITCONCERN, CONCERN

This field indicates the reason for the audit priority. You should not use the exact value of this field. The AUDITCONCERN field can contain one or more concerns separated by commas. If a concern results from the IBM supplied IEFSDPPT for the specific OS level, the AUDITCONCERN is suffixed with the text "(IBM default)", and the AUDITPRIORITY is adjusted. The following audit concerns are currently defined:

- Bypasses SAF.

  Data set accesses by the program are not subject to SAF (System Authorization Facility) security checks. This might be very dangerous if the program can be called by arbitrary users and be induced to read from or write to user-specified data sets. Bypassing SAF is a direct violation of the B1 security policy. If B1 policy is specified such violation is indicated by a suffix of " / not B1 compliant" and high audit priority.
- Executes in system key .

  The task runs in a system key. This authorizes the task to bypass system security.
- No data set integrity

  This option turns off all data set serialization once the program is started. For instance, data sets used by the program can be deleted by another program while being used; this might mean the task can be brought down by accident.
- Modified from IEFSDPPT.

  The PPT entry was modified from the system default.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 378. PPT NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

BYPASS

Flag field that indicates if DFSMS (DFP) will bypass SAF (System Authorization Facility) calls. If set, data set accesses by the program are not subject to security checks by RACF.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. The complex name can come from the ALLOC COMPLEX parameter or default to a system name.

DEFAULT

Flag field that indicates if the current entry is a default PPT entry. It is set for entries derived from the IEFSDPPT load module, and not set for entries set by parmlib member SCHEDxx.

HONOR_IEFUSI_REGION

Flag field that indicates if a program is to honor region size restrictions specified in MVS exit IEFUSI. The values that can be returned are:

Yes
The program honors a region size limit set in IEFUSI.

No
The program honors a region limit set in IEFUSI.

This setting is only available in z/OS Version 1 Release 10 and later. No value is returned for systems running earlier z/OS releases.

KEY

The storage protection key in which the program (job step) runs, if one was assigned. This is a decimal number in the range 0 to 15. If no storage key was assigned, this field is left blank. Keys in the range 0 to 7 imply system authorization.

NODSI

Flag field that indicates if the program requires data set integrity. If set (NODSI=YES), the program does not hold an enqueue for data sets allocated in batch (the NODSI parameter does not apply to dynamic allocations). The lack of enqueues can cause problems with data management procedures that might (re)move the data set while it is being used by the program that has NODSI.

NONCANCEL

Flag field that indicates if the program can be cancelled or not. If set (NONCANCEL=YES), the program cannot be cancelled with an MVS CANCEL command. In that case, the program can only be cancelled using the FORCE ARM command.

NONSWAP

Flag field that indicates the program is to be swappable or not. If set (NONSWAP=YES), the program is marked non-swappable.

PRIV

Flag field that indicates if the program executes privileged or not. If set (PRIV=YES), the address space in which the program is running is not swapped unless it is in a long wait state.

Note: This field should not be confused with the RACF TRUSTED or PRIVILEGED attributes.

PROGRAM

The name of the program. When combined with the SYSTEM field, this field uniquely identifies an entry in the NEWLIST TYPE=PPT.

SYSTASK

Flag field that indicates if the program is a system task. If set (SYSTASK=YES), the program is a system task and is not timed. (In this case, it must be a one-step job started by a START or MOUNT command.)

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. The field length is 8 characters for compatibility with other NEWLIST types. When combined with the PROGRAM field, this field uniquely identifies an entry in the NEWLIST TYPE=PPT.

RACF: RACF profiles

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•	•	•	•	•		

The RACF NEWLIST (NEWLIST TYPE=RACF) provides information about the RACF profiles in the database. Unlike the other NEWLIST types, the available fields are not fixed, but depend on the templates in the RACF database, which determine the layout and contents of the profiles in the database. This topic describes the fields available in supported RACF releases. In addition to the RACF template fields, some fields are added by zSecure, and you can define custom fields for this NEWLIST.

A number of standard defined variables for RACF profiles are also provided in the SCKRCARL library member C2RXDEF1, which is included in the user interface as well as in certain batch jobs. These defined variables are also documented in this topic.

You can list the database templates available on your system by issuing the TEMPLATE primary command, or by selecting the TEMPLATE option from the **AU.S - RACF** control menu option. See "TEMPLATE - Template field properties" on page 284.

In the RACF NEWLIST, the fields COMPLEX CLASS KEY SEGMENT PROFTYPE VOLSER uniquely identify an entry. An alternate key is COMPLEX DB RBA.

For performance reasons, profiles are normally stored in RACF databases in segments and not as a single record. However, RACF databases prior to V1.9.2 and non-RDS RACF databases do not necessarily follow this practice. The records returned by the RACF NEWLIST type are these profile segments, not entire profiles. If you only want to list basic profile information, include the SEGMENT=BASE option in your selection statement. This option suppresses extra lines for the other segments and only shows the profile class and key.

You can combine information from different segments into one line with a lookup operation. For example, to combine a user default account from the TSO segment with the user name from the BASE segment, include the option SEGMENT=TSO in your selection and PGMRNAME in the output specification. Conversely, you can select on a base segment property and then do a lookup to an application segment.

Note: The LIST command generates output while reading each record to conserve storage, and therefore does not support lookup operations.

Another way of combining information from different segments is to use a MERGELIST statement. The separate NEWLIST statements within the MERGELIST can then separately select and format the BASE, TSO, and other segments. If you sequence the statements according to class and key, the output for each profile is written on consecutive lines.

Table 379 lists the predefined segment types:

Table 379. RACF Profiles: Predefined segment types

Segment type	Entity types
CDTINFO	GENERAL (CDT)
CERTDATA	GENERAL (DIGTCERT and DIGTRING)
CICS	USER
DCE	USER
DFP	GROUP, USER, DATASET
DLFDATA	GENERAL (DLFCLASS)
EIM	USER, GENERAL (FACILITY and LDAPBIND)
ICSF	GENERAL (CSFKEYS, GCSFKEYS, XCSFKEY,and GXCSFKEY)
KERB	USER, GENERAL (REALM)
LANGUAGE	USER
LNOTES	USER
NDS	USER
NETVIEW	USER
OMVS	USER, GROUP
OPERPARM	USER
OVM	GROUP, USER
PROXY	USER, GENERAL (FACILITY and LDAPBIND)
SESSION	GENERAL (APPCLU)
SIGVER	GENERAL(PROGRAM)
SSIGNON	GENERAL (PTKTDATA)
STDATA	GENERAL (STARTED)
SVFMR	GENERAL (SYSMVIEW)
TME	GROUP, GENERAL (ROLE), DATASET
TSO	USER
WORKATTR	USER

For information about the RACF NEWLIST fields available for reporting, see "Field descriptions" on page 1126.

In the RACF NEWLIST, custom field names can be defined in the CFIELD class. For user and group resource profiles, the custom field values are in the CSDATA segment. If you use these fields in a SELECT statement, explicitly specify the class (USER or GROUP) and SEGMENT=CSDATA. The fields CSCNT, CSTYPE, CSKEY, and CSVALUE are never interpreted as custom fields, but are always interpreted as representing the actual fields in the CSDATA segment. If you define custom fields using these names, you can access the fields by using the CUSTOM_DATA field or the statement SUBSELECT CUSTOM_DATA. See "CUSTOM_DATA" on page 1157.

Custom fields use the default formats, depending on the CFDTYPE field as defined in the CFDEF segment of the CFIELD profiles and loaded into the dynamic parse table. Table 380 lists the default formats. See "Format names for input and output" on page 810 for additional information on these formats.

Table 380. RACF Custom fields - default formats

Format	Description
CFDTYPE	Default
CHAR	Character
NUM	Numeric
HEX	Hexadecimal
FLAG	A $YESNO format

Field descriptions

The RACF NEWLIST provides the following types of fields for reporting.

ACL

This repeated field can be used to display the access and conditional access lists of a profile. It can only be used for output on the SORTLIST, DISPLAY, and (D)SUMMARY commands (use the fields listed with ACLCNT and ACL2CNT for SELECT/EXCLUDE processing). This field is found in GROUP, DATASET, and GENERAL profiles; in group profiles, it does not contain useful information.

The display contains userid, access, ACL id, conditional class, and conditional profile name. The default output length is 45, but since it contains a profile name that can be up to 255 characters, the maximum output length of the ACL field is 290 characters. Use the EXPLODE output modifier for a complete access list including access per user through each connect group; use the RESOLVE output modifier for a resolved access list showing the highest access of each user or group. Use EFFECTIVE to extend the resolved access list into the effective one, which also includes access due to operations or group operations. Be aware that connect information is needed for RESOLVE, EFFECTIVE and EXPLODE, so it works best if specified in the scope of a NEWLIST, while there are no outer selections or with the UNIVERSAL modifier specified to force collection of all relevant data. The SCOPE modifier can be used to extend EXPLODE/RESOLVE/EFFECTIVE with administrative access.

To display only selected repeat group entries, the DEFINE SUBSELECT command can be used. See "Subselect clauses" on page 755. To select on specific combinations of values per repeat group entry, the SELECT ACL(...) command can be used. See "SELECT/EXCLUDE ACL(...)" on page 890. For a list of access level see Table 304 on page 877.

To print just the ids or the access levels or both the ACLACCESS, ACLID and ACLIDACCESS formats can be used. See "Specifying syntax for RACF command input" on page 810.

Warning: This field should *not* be combined with the USERID field to list user/group entries. The ACL and USERID fields might have a different sort order and a different number of entries. If you want to show user- or group-related information next to an ACL field, use the ACL field as a base field, ACL:PGMRNAME for example.

ACL2ACC

For GENERAL profiles: the access level in a conditional access list, access list entries listed in the ACL2NAME, ACL2UID, ACL2ACNT, and ACL2RSVD fields. The number of conditional access list entries is listed in the ACL2CNT field. The preferred interface to this field is the ACL combination field.

ACL_ALTER

Variable defined in C2RXDEF1 that lists the ACL ids with `ALTER` access.

ACL_CONTROL

Variable defined in C2RXDEF1 that lists the ACL IDs with `CONTROL` access.

ACL_EXECUTE

Variable defined in C2RXDEF1 that lists the ACL IDs with `EXECUTE` access.

ACL_NONE

Variable defined in C2RXDEF1 that lists the ACL IDs with `NONE` access.

ACL_OPER

Variable defined in C2RXDEF1 that lists the ACL IDs with `ALTER-O` access; that is, access if provided through the `OPERATION` or group-`OPERATIONS` attributes.

ACL_READ

Variable defined in C2RXDEF1 that lists the ACL IDs with `READ` access.

ACL_UPDATE

Variable defined in C2RXDEF1 that lists the ACL IDs with `UPDATE` access.

ACL2ACNT

For GENERAL profiles: the number of access events for each entry in a conditional access list. This number is only updated for discrete profiles, and only if statistics are on (due to SETROPTS STATISTICS). This is a repeated field that can be combined with the ACL2NAME, ACL2UID, ACL2ACC, and ACL2RSVD fields. The number of conditional access list entries is listed in the ACL2CNT field.

ACL2CNT

This field lists the number of conditional access list entries. For DATASET profiles, the PROGRAM, USR2ACS, PROGACS, PAS2CNT, and ACL2VAR fields list the entries and access. For GENERAL profiles, the ACL2NAME, ACL2UID, ACL2ACC, ACL2ACNT, and ACL2RSVD fields list the entries and access. The preferred interface to this field is the ACL combination field.

ACL2NAME

For GENERAL profiles: the indicator byte in a conditional access list. This is a repeated field that can be combined with the ACL2UID, ACL2ACC,

ACL2ACNT, and ACL2RSVD fields. The number of conditional access list entries is listed in the ACL2CNT field. The preferred interface to this field is the ACL combination field.

ACL2RSVD

For GENERAL profiles: the conditional data in a conditional access list, containing class and profile name. This is a repeated output-only field that can be combined with the ACL2NAME, ACL2UID, ACL2ACC, and ACL2ACNT fields. The number of conditional access list entries is listed in the ACL2CNT field. The preferred interface to this field is the ACL combination field.

ACL2UID

For GENERAL profiles: the user or group in a conditional access list. This is a repeated field that can be combined with the ACL2NAME, ACL2ACC, ACL2ACNT, and ACL2RSVD fields. The number of conditional access list entries is listed in the ACL2CNT field. The preferred interface to this field is the ACL combination field.

ACL2VAR

For DATASET profiles, reserved field which forms part of a conditional access list entry. This is a repeated output-only field that can be combined with the PROGRAM, USER2ACS, PROGACS, and PAS2CNT fields. The number of conditional access list entries is listed in the ACL2CNT field. The preferred interface to this field is the ACL combination field.

ACLCNT

This field is found in DATASET, group and general profiles. For DATASET and general resource profiles, it lists the number of access list entries. For user profiles, it lists the number of users connected to a group. The entries are listed in the USERID, USERACS, and ACSCNT fields. The preferred interface to this field is the ACL combination field for DATASET and general resource profiles or the CONNECT combination field for group profiles. For a group with the universal attribute, this field counts only the users with higher than default authority to the group. To see the total number of users, use the CONNECT_COUNT field.

ACSALTR

This numeric field (a decimal number of up to 5 digits) is found in DATASET and GENERAL profiles. It indicates the number of times the data set or resource was successfully accessed with ALTER authority. This number is only updated for discrete profiles, and only then if statistics are on (due to SETROPTS STATISTICS).

ACSCNT

This field is found in DATASET, GROUP, and GENERAL profiles. It is a repeated field that can be combined with the USERID and USERACS field. The ACLCNT field lists the number of entries.

For group profiles, this field has no meaning. For DATASET and GENERAL profiles, this field lists the number of times an access list entry was used. This number is only updated for discrete profiles, and only then if statistics are on (due to SETROPTS STATISTICS).

ACSCNTL

This numeric field (a decimal number of up to 5 digits) is found in DATASET and GENERAL profiles. It indicates the number of times the data set or resource

was successfully accessed with CONTROL authority. This number is only updated for discrete profiles, and only then if statistics are on (due to SETROPTS STATISTICS).

ACSREAD

This numeric field (a decimal number of up to 5 digits) is found in DATASET and GENERAL profiles. It indicates the number of times the data set or resource was successfully accessed with READ authority. This number is only updated for discrete profiles, and only then if statistics are on (due to SETROPTS STATISTICS).

ACSUPDT

This numeric field (a decimal number of up to 5 digits) is found in DATASET and GENERAL profiles. It indicates the number of times the data set or resource was successfully accessed with UPDATE authority. This number is only updated for discrete profiles, and only then if statistics are on (due to SETROPTS STATISTICS).

ADSP

This field is an alias for the FLAG1 field found in USER BASE segments (and non-RDS CONNECT profiles). It indicates whether the user has the system-ADSP (or group-ADSP, resp.) attribute. It can be specified as an attribute, e.g. SELECT ADSP. Its opposite for the purpose of SELECT/EXCLUDE processing is NOADSP.

If the user has the ADSP attribute, a discrete profile is created every time the user creates a permanent DASD or tape data set. If assigned at the group level (in a CONNECT profile), ADSP is only in effect when that group is the user's current connect group. The ADSP attribute is only used if system-ADSP is in effect (due to SETROPTS ADSP). This is indicated by the ADSP field of NEWLIST TYPE=SYSTEM.

On standard userid overviews, this field is usually shown as the first position in a group column headed AG (ADSP and GRPACC).

ANY_CERT

Variable defined in C2RXDEF1 that is true for a userid that has at least one digital certificate. By default it displays *C* when true and blanks otherwise.

ANY_CLAUTH

Variable defined in C2RXDEF1 that is true for a userid that has class authorization in any class. By default it displays *C* when true and blanks otherwise.

ANY_GROUP_SOA

Variable defined in C2RXDEF1 that is true for a userid that has the any of the following group attributes: `SPECIAL`, `OPERATIONS`, or `AUDITOR`. By default it displays *g* when true and blanks otherwise.

ANY_LINK

Variable defined in C2RXDEF1 that is true for a userid that has any RACLINK associations. By default it displays *L* when true and blanks otherwise.

ANYSUPGROUP

This field is only found in group profiles and is a repeat group showing all superior groups. The order is from nearest to SYS1.. This field result in two passes through the database and can only be used on UNLOAD files, not on the live RACF database.

APPLDATA

This field is only found in GENERAL profiles and contains application data. This data is used by various applications, for instance by IMS, and zSecure Command Verifier.

Because APPLDATA can be used by both applications from IBM and other vendors, RACF command processing cannot validate the data. Because misspellings typically result in *not* applying the requested setting, zSecure Admin and Audit verifies a number of well-documented APPLDATA values. If a user changes the value of an APPLDATA field on an ISPF panel and that value is not recognized by zSecure Admin and Audit, a panel is presented prompting the user to select a documented value for the field or to keep the modified value specified.

In addition, an audit concern is generated for unrecognized values.

Table 381 shows which text string is recognized in which profile. APPLDATA fields can contain more text than the text to enable the setting. The strings are recognized when they are separated from any other text by blanks.

Table 381. Recognized APPLDATA value per class / profile

Class	Profile	Recognized APPLDATA value
CSFSERV / CSFKEYS	Any	RACF-DELEGATED
PTKTDATA	Any	NO REPLAY PROTECTION
FACILITY	IRR.PGMSECURITY	BASIC ENHANCED ENHANCED-WARNING
TIMS / GIMS	Any	REVERIFY

For digital certificates the APPLDATA field contains the userid associated with the certificate. For selection ease the field CERTIFICATE_ID can be used instead, which is equal to APPLDATA for the class DIGTCERT, and absent for all other classes.

ASSIZEMAX

This field is found in user profiles and is part of the OMVS segment. It indicates the maximum address space region size. It lies between 10,485,760 and 2,147,483,647.

ASYMUSAGE

See “CSFAUSE” on page 1154.

AUDIT

This flag field is found in DATASET and GENERAL profiles and indicates the audit flags set by the owner. These flags determine whether to log successful and failed accesses. The audit qualifiers determine the level from which accesses are logged; these are listed in the AUDITQF and AUDITQS fields. See also the GAUDIT field, which lists the audit flags set by the auditor. The easiest way to print the audit info is through the AUDITLVL, AUDITS, or AUDITF fields. Use the AUDITLVL field for modifiable displays.

The following table lists the AUDIT values and their meanings.

Table 382. Audit flag values and descriptions

AUDIT value	Meaning
ALL	Audit successful accesses from AUDITQS and failed accesses from AUDITQF.
SUCCESS	Audit successful accesses from AUDITQS.
FAILURE	Audit failed accesses from AUDITQF.
NONE	No auditing.

AUDITCONCERN, CONCERN

This field returns a concatenation of audit concerns for the profile. The following table shows the default audit priority for active and non-active classes and lists the audit concern. The table sorts audit concerns by highest audit priority without a policy statement.

Table 383. Audit priorities and concerns by class

Active class	Non-active class	Audit concern
30	30	Can logon without password
25	25	UNIX security labels are bypassed
20		Generic not active
15	1	Class not in CDT
15	1	Class not in router table
15	1	Possibly misspelled APPLDATA
11	1	Warning mode does not prevent access
10	1	Range table ignores profile
10	1	Verify why UACC>=UPDATE
10	1	UNIX ID sharing not protected because UACC greater than or equal to read
6	6	Program control inactive
6	1	Generic chars in discrete key
6	1	Generic chars in discrete member
6	1	No replay protection
4	4	Global access checking inactive
4	4	Profile not used because no such class
4	4	Profile ignored
4	1	Profile not used for access control
4	n/a	Profile probably not used because it is not RACLISTed.
n/a	1	Profile not effective
1	1	Class inactive

The priority is 40 if the concern is not compliant to the policy that has been selected. A priority of 0 means the concern is not issued unless the policy has explicitly been requested.

The following audit concerns have been defined:

Can logon without password

The userid is authorized to logon (not PROTECTED), but has no password and does not need to supply an OIDCARD either. Therefore, the userid can be used to logon without proper authentication.

UNIX security labels are bypassed

Defining the BPX.SAFFASTPATH profile in the FACILITY class causes z/OS UNIX to bypass RACF in some cases to improve performance, and you should not bypass RACF in a multilevel-secure environment.

Generic not active

This is a generic profile but its class is active and does not have generics activated. This means that this profile is not used for access checking. This could lead to unprotected data.

Class not in CDT

The class to which this profile belongs is not defined in the Class Descriptor Table. Any authority check for this profile results in a return code of 4 (profile not found) from RACF. Most applications grant access in this situation.

Class not in router table

The class to which this profile belongs is not found in the router table, which means that RACROUTE requests result in a *not protected* return code. Most applications grant access in this situation. On z/OS V1R6 and higher systems the router table is optional, and this audit concern is no longer generated.

Possibly misspelled APPLDATA

This concern is explained in detail in the APPLDATA field description.

Warning mode does not prevent access

This profile is in warning mode, which means that every access request is successful, though logging is done for each access that is not specifically granted through other means. This function should only be used temporarily while determining which access is necessary to the data protected by this profile.

Range table ignores profile

This profile does not fall within any of the ranges defined in the Range Table, so RACF is not able to use it for access control.

Verify why UACC>=UPDATE

A UACC value greater than update is extremely unusual because it grants almost unlimited access to all users. Do not specify this value unless absolutely necessary.

UNIX ID sharing not protected because UACC greater than or equal to read

Users that have access to the SHARED.IDS profile in the UNIXPRIV class and haveUPDATE access to the UID or GID fields, are able to use the SHARED keyword of the RACF ADDUSER, ALTUSER, ADDGROUP and ALTGROUP commands, allowing him or her to create users or groups using already existing user and group IDs. This new user or group has access to all the resources the already existing user or group has access to which is potentially dangerous.

Program control inactive

This profile belongs to the PROGRAM class, indicating that it contains a program that should be protected by RACF. However, program control is not active so RACF does not have any control over the access to this program.

Generic chars in discrete key

In these cases, the profile contains the actual asterisk or percent sign, instead of the internal representation used by RACF for generic profiles. Generally, these profiles are a result of errors, such as trying to define a generic profile before the class is enabled for generic profiles. The profiles can be deleted after turning generic command processing off for the class using the command SETROPTS NOGENCMD(*class*) NOGENERIC(*class*).

Generic chars in discrete member

This profile contains generic characters in its discrete member list. This is usually the result of an error.

No replay protection

The PTKTDATA profile specifies that `PassTickets` validated by the key in the SIGNON segment can be used multiple times. Only use this function in secure environments where access to generated `PassTickets` is limited within a secure or internal network. The use of `PassTickets` is still more secure than the use of normal passwords, as `PassTickets` are only valid during a 10 minute interval.

Global access checking inactive

This profile belongs to the GLOBAL class, indicating that it contains a definition for global access to be allowed for the class described by the profile. However, global access checking for that class is inactive, so this definition is not used.

Profile not used because no such class

This profile belongs to the GLOBAL class, indicating that it contains a definition for global access to be allowed for the class described by the profile. However, this class does not exist, so the definition is not used.

Profile ignored

This profile belongs to a member class that is not supposed to contain profiles, and which does not use profiles.

Profile not used for access control

For any one of a variety of reasons, this profile is not used for access control. This could lead to unprotected data.

Profile probably not used because not raclisted
A profile in an active class that has the RACLIST required property is not RACLISTed. This conditionally replaces the existing audit concern 'Profile not used for access control' (which is retained if the class is inactive).

Profile not effective
This profile belongs to an class that must be active but that has a function different from access checking, while the class in inactive. This is shown instead of the concern 'Profile not used for access control' because the class is not used for access control.

Class inactive
The class to which this profile belongs is inactive, so this profile is never used for access control.

AUDITF

This derived field contains the AUDIT(FAILURES) level. It is based on the raw AUDIT and AUDITQF fields. The possible values are listed in the following table. The blank (X'FF') value means that failure auditing is not active. It is meant for use in SELECT statements. Use the AUDITLVL field for modifiable displays.

Table 384. AUDITF values

AUDITF value	Internal value (hex)
ALTER	03
CONTROL	02
UPDATE	01
READ	00
(blank)	FF

AUDITLVL

This field is found in DATASET and GENERAL profiles; it contains the audit level (both successes and failures) in a three-character format: a success level, a blank, and a failures level. The audit levels can have the values blank (not set), 'R' (READ), 'U' (UPDATE), 'C' (CONTROL), and 'A' (ALTER). It is the only modifiable audit field.

AUDITOR

This field is an alias for the FLAG6 field found in USER BASE segments. It indicates whether the user has the system-auditor attribute. It can be specified as an attribute, SELECT AUDITOR for example. Its opposite for the purpose of SELECT/EXCLUDE processing is NOAUDITOR.

On standard userid overviews, this field is usually shown as the last position in a group column headed SOA which represents the SPECIAL, OPERATIONS, and AUDITOR attribute settings.

This field returns the audit priority for the profile. See field AUDITCONCERN for a table with the concerns and their priorities. The actual audit priority can be higher because of a SIMULATE POLICY C2 statement for example.

AUDITQF

Flag field that indicates the audit failure qualifier. This field is found in `DATASET` and general profiles.

If the `AUDIT` field is set to *ALL* or *FAILURE*, all failed accesses with intended access equal or higher than this field are logged. The `AUDITQF` field is unpredictable when failure auditing has not been specified. Use `AUDITF` instead. Use the `AUDITLVL` field for modifiable displays.

The `AUDITQF` values are listed in the following table.

Table 385. AUDITQF values

AUDITQF value	Internal value (hex)
ALTER	03
CONTROL	02
UPDATE	01

Table 385. AUDITQF values (continued)

AUDITQF value	Internal value (hex)
READ	00
NONE	FF

AUDITQS

Flag field that indicates the audit success qualifier. This field is found in DATASET and general resource profiles.

If the *AUDIT* field is set to *ALL* or *SUCCESS*, all successful accesses with intended access equal or higher than this field are logged. The AUDITQS field is unpredictable when success auditing has not been specified. Use AUDITS instead. Use the AUDITLVL field if you want to permit users to change values on the display panels.

The following table lists the AUDITQS values:

Table 386. AUDITQS values

AUDITQS value	Internal value (hex)
ALTER	03
CONTROL	02
UPDATE	01
READ	00
NONE	FF

AUDITS

This field contains the AUDIT(SUCCESS) level. It is based on the raw AUDIT and AUDITQS fields. The possible values are listed in the following table. The blank (X'FF') value means that success auditing is not active. It is meant for use in SELECT statements. Use the AUDITLVL field for modifiable displays.

AUDITS value	Internal value (hex)
ALTER	03
CONTROL	02
UPDATE	01
READ	00
(blank)	FF

AUTHDATE, CREADATE, DEFDATE

This field is found in all profile types. It indicates the date the profile was created, for example the date the object was defined to RACF.

AUTHOR

This is an alias of OWNER (see “OWNER” on page 1187).

AUTO

This is an alias of AUTOTAPE (see "AUTOTAPEDSN, AUTO").

AUTOTAPE, AUTO

This field can only be used for SELECT/EXCLUDE processing. It corresponds to bit 1 in the RESFLG field found in TAPEVOL BASE segments. It indicates automatic TAPEVOL profiles. It can be specified as an attribute, SELECT AUTOTAPE for example. Its opposite for the purpose of SELECT/EXCLUDE processing is NOAUTOTAPE. See also the RESFLG field.

BINDDN

This field is found on the PROXY segment of USER and FACILITY class general resource profiles. It specifies the distinguished name (DN) which the z/OS LDAP Server uses when acting as a proxy on behalf of a requester.

BINDPW

This field is found on the PROXY segment of USER and FACILITY class general resource profiles. It contains an LDAP BIND password, and is therefore considered highly confidential. It is not shown on any display or list, and is stored in any unload as *****. It can only be used in SELECT/EXCLUDE processing with the EXISTS or MISSING keyword.

BINDPWKY

This field is found on the PROXY segment of USER and FACILITY class general resource profiles. It contains the encryption method and/or reference to the key of an LDAP BIND password.

CATEGORY

This field is found in USER, DATASET, and GENERAL profiles. For SELECT/EXCLUDE processing, a hexadecimal (internal) value must be specified. It is a repeated field listing the security categories to which the user has access, or to which the data set or resource belongs. The number of security categories is listed in the NUMCTGY field.

CDTINFO segment fields

The following fields provided information about the CDTINFO segment.

CDTCASE, CLASS_CASE_ASIS

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see “CLASS: RACF Class Descriptor Table” on page 989. This field indicates whether profile names in the user-defined class are kept as is or are converted to upper case. The field has a flag format where "Yes" means that the case is preserved, and "No" means that names are converted to uppercase. Use the overriding flag format $CASE to output "UPPER" or "ASIS".

CDTDFTRC, CLASS_DFLTRC

This field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see “CLASS: RACF Class Descriptor Table” on page 989. This field contains the default return code for the user-defined class. This code is returned when no matching profile can be found in a RACHECK. The return codes and their meaning are documented in the following table.

Table 387. CDTFTRC return codes and descriptions

CDTDFTRC value	Meaning
0	Allow access
4	Indeterminate: depends on resource manager

Table 387. CDTFTRC return codes and descriptions (continued)

CDTDFTRC value	Meaning
8	Fail access

CDTFIRST, CLASS_SYN1RAW

This field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field contains the syntax rules for the first character of a profile name in the user-defined class. By default this field outputs a four byte character field AN#S. Use overriding format $SYN for command generation. See also CLASS_SYN1ALP, CLASS_SYN1NAT, CLASS_SYN1NUM and CLASS_SYN1SPE.

CDTGEN, CLASS_GENERIC_ALLOWED

This field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class. See "CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether SETROPTS GENERIC and SETROPTS GENCMD are authorized for the class. It corresponds to the GENERIC_ALLOWED field in CLASS NEWLIST, see "GENERIC_ALLOWED" on page 997.

CDTGENL, CLASS_GENLIST_ALLOWED

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether the user-defined class might be GENLISTed (by using the SETROPTS GENLIST command). Generic profiles for this class are then kept in storage that is shared by all address spaces.

Table 388. CDTGENL values

CDTGENL value	Meaning
Allowed	The GENLIST operation is permitted for this class.
Disallowed	The GENLIST operation is not permitted for this class.

CDTGROUP, CLASS_XGROUP

This field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. For member classes, this field contains the name of the related grouping class. For non-member classes this field is blank. See also CDTMEMBR.

CDTINFO

This field can only be used for SELECT/EXCLUDE processing. It selects CDTINFO segments.

CDTKEYQL, CLASS_QUAL

This field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field contains the number of qualifiers at the start of the profile name that cannot be generic. This is a number in the range 0 to 123; the default is 0. During access

verification, RACF ignores all profiles that have generic characters in the specified number of qualifiers. This also controls which profiles are loaded (and kept) in storage.

CDTMAC

This field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field indicates the way Mandatory Access Control (MAC) uses SECLABELs for the user-defined class. This setting is used only when the SECLABEL class is active. The following table shows the possible values for CDTMAC. See also CLASS_EQUALMAC and CLASS_RVRSMAC.

Table 389. CDTMAC values

CDTMAC value	Meaning
Normal	The SECLABEL of the user must dominate the SECLABEL of the resource to grant access.
Equal	The SECLABEL of the resource and the user must be equivalent
Reverse	The SECLABEL of the resource must dominate SECLABEL of the user to grant access.

CDTMAXLN, CLASS_MAXLEN_ENTITY

Specifies the backward compatible maximum profile name length to be used with the ENTITY keyword form of the RACROUTE macro. The value is a number in the range 1 - 246. The default value is *8*. This field comes from the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class. See "CLASS: RACF Class Descriptor Table" on page 989.

This length value is required with the ENTITY keyword form of the RACROUTE macro because that macro form does not pass the return buffer length. As a result, if the maximum profile name length increases, existing applications might break if the entire profile names were returned.

You can avoid this problem by using the ENTITYX keyword form of RACROUTE macro instead. If that form is used, the limit does not apply. See also CDTMAXLX, which contains the true maximum profile name length, if it is different.

CDTMAXLX, CLASS_MAXLEN

Contains the maximum length of resource and profile names for the user-defined class. The value can be a number in the range 1 - 246. By default, the field is missing. This field comes from the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class. See "CLASS: RACF Class Descriptor Table" on page 989. See also CDTMAXLN.

CDTMEMBR, CLASS_XMEMBER

This field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. For grouping classes, this field contains the name of the related member class. For non-grouping classes this field is blank. See also CDTGROUP.

CDTOPER, CLASS_OPER

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether OPERATIONS authority is honored for the user-defined class.

CDTOTHER, CLASS_SYNRRAW

This field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field contains the syntax rules for the remainder characters of a profile name in the user-defined class. By default this field outputs a four byte character field "AN#S". Use overriding format $SYN for command generation. See also CLASS_SYNRALP, CLASS_SYNRNAT, CLASS_SYNRNUM and CLASS_SYNRSPE.

CDTPOSIT, CLASS_POSIT

This field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field contains the options set id, a number in the range 0 to 1023 identifying a set of SETROPTS options that govern the activity of the user-defined class and all other classes having the same POSIT value. Whenever a SETROPTS command is issued for any class with a specific POSIT value, it applies to all classes with that same POSIT.

POSIT values in the range 0-18, 57-127, and 528-1023 are reserved for use by IBM; numbers 19-56 and 128-527 are installation-defined.

CDTPRFAL

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether profiles are permitted in the user-defined class.

CDTRACL

This field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether profiles in the user-defined class might or might not be SETROPTS RACLISTed, or are required to be RACLISTed. If a class is RACLISTed, both generic and discrete profiles for this class are loaded into storage that is shared between all address spaces. Below is a table documenting the different settings. See also CLASS_RACLIST_ALLOWED and CLASS_RACLREQ.

Table 390. CDTRACL values

CDTRACL value	Meaning
Disallowed	The RACLIST operation is not permitted for this class.
Allowed	The RACLIST operation is permitted for this class, but it is not mandatory.
Required	The RACLIST operation is mandatory for this class.

CDTSIGL, CLASS_SIGNAL

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see

"CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether an ENF signal must be sent when the user-defined class is being RACLISTed, NORACLISTed, or RACLIST REFRESHed.

CDTSLREQ, CLASS_SECLABEL

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether security labels are required for resources in the user-defined class. Note that when the SECLABEL class is active, and a security label exists for a resource, the security label for the resource is used during authorization checking, even when security labels are not required.

CDTUACC, CLASS_UACC

Contains the default universal access authority (UACC) for the user-defined class. If no UACC is specified on the command when a profile in this class is added, this default UACC is used to set the profile UACC. The special value ACEE indicates that the UACC is taken from the accessor environment element (ACEE) of the user, which is specified by the UACC on the ADDUSER, ALTUSER or CONNECT command.

This field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class. See "CLASS: RACF Class Descriptor Table" on page 989. Table 391 lists the possible UACC values in descending sort order:

Table 391. CDTUACC field - possible UACC values

UACC value	Description
ALTER	• For discrete profiles, ALTER indicates that, by default, all users have control over the resource and the resource profile and can authorize other users or groups (or both) to access the resource. • For generic profiles, ALTER indicates that, by default, all users have control over the resource and can allocate data sets protected by the generic profile. Only the profile owner has full control over the resource profile.
CONTROL	Indicates that, by default, all users have access authority to update, insert, or delete records in the VSAM data set and perform other operations as if the data set password were supplied.
UPDATE	Indicates that, by default, all users can access the resource for both reading and writing.
READ	Indicates that, by default, all users can access the resource for reading only. NONE indicates that, by default, users cannot access the resource.
NONE	Indicates that, by default, users cannot access the resource.
ACEE	Indicates that the UACC is taken from the accessor environment element (ACEE).

CERT and DIGCERT segment fields

The following fields provide information about the CERT and DIGCERT segments.

CERT

Contains the digital certificate in BER-encoded form. This field is only present in profiles in the DIGTCERT class and is part of the CERTDATA segment.

CERTCT

The count of digital certificates associated with this RACF userid or connected to this keyring. This field is only present in the BASE segment of the user profile and the CERTDATA segment of the DIGTRING general resource class. The keys for these certificates are listed in CERTNAME. See also CERTIFICATE_ISSUER and CERTIFICATE_SERIAL.

CERTDATA

Selects CERTDATA segments. This field can only be used for SELECT or EXCLUDE processing.

CERTDFLT

Repeat group field that signifies whether the associated digital certificate is the default certificate for this keyring. The repeat count is stored in the CERTCT field. This field is only present in the CERTDATA segment of the DIGTRING general resource class.

CERTEND

Contains the date and time signifying the end of the validity of this digital certificate. This field is only present in the CERTDATA segment of the DIGTCERT general resource class.

CERTIFICATE_ALT_DOMAIN

Contains the domain names of the subject as found in the subjectAltName extension of the certificate. This field is only present in the CERTDATA segments of profiles in the DIGTCERT class.

CERTIFICATE_ALT_EMAIL

Contains the email addresses of the subject as found in the subjectAltName extension of the certificate. This field is only present in the CERTDATA segments of profiles in the DIGTCERT class.

CERTIFICATE_ALT_IP

Contains the IP address of the subject as found in the subjectAltName extension of the certificate. This field is only present in the CERTDATA segments of profiles in the DIGTCERT class.

CERTIFICATE_ALT_URI

Contains the universal resource identifiers of the subject as found in the subjectAltName extension of the certificate. This field is only present in the CERTDATA segments of profiles in the DIGTCERT class.

CERTIFICATE_ID

Contains the user ID that the digital certificate is related to. This field is only present in the CERTDATA segments of profiles in the DIGTCERT class. When present, the contents of the field is identical to that of the APPLDATA field.

CERTIFICATE_ISSUER

Contains the distinguished name of the issuer of the digital certificate or an approximation of the name. This field is only present for profiles in the DIGTCERT class.

Together with the CERTIFICATE_SERIAL, the CERTIFICATE_ISSUER is a key for the certificate. These fields are derived from the profile KEY, which consists of the serial number and issuer separated by a period. The maximum length for the profile KEY is 246 characters. If the distinguished name for the

certificate issuer is particularly long, the distinguished name portion of the profile key is abbreviated. Abbreviated names are indicated by hash marks in the name portion of the key. If the distinguished name is abbreviated, the value for the CERTIFICATE_ISSUER contains the abbreviated name. The full name can be obtained from the CERTIFICATE_ISSUER_FULL field.

CERTIFICATE_ISSUER_FULL

Contains the full distinguished name of the subject of the certificate issuer. This field is only present in the CERTDATA segment of profiles in the DIGTCERT class. This field is obtained from the certificate, as opposed to CERTIFICATE_ISSUER field which is derived from the profile KEY. See also "CERTIFICATE_ISSUER" on page 1141, "CERT" on page 1140, and CERTIFICATE_SUBJECT.

CERTIFICATE_KEYUSAGE

Contains the keyUsage extension of the certificate. The value can be shown in the KEYUSAGE_RACF format, which is the default RACF format, or it can be shown in the KEYUSAGE_X509 format as defined by the X.509 standard. This field is only present CERTDATA segments of profiles in the DIGTCERT class. See "Specifying syntax for RACF command input" on page 810 for a more detailed description of the formats.

CERTIFICATE_SERIAL

Contains the serial number of the digital certificate. This field is only present for profiles in the DIGTCERT class. Together with the CERTIFICATE_ISSUER field, this is a key for the certificate. These fields are derived from the profile KEY, which consists of the serial number and the issuer separated by a period. See also CERT and CERTIFICATE_ISSUER.

CERTIFICATE_SUBJECT

Contains the distinguished name of the subject of the certificate–the user for whom the certificate was issued. This field is only present for profiles in the DIGTCERT class. This field is interpreted from the actual certificate. See also "CERT" on page 1140 and "CERTIFICATE_ISSUER" on page 1141.

CERTIFICATE_TRUSTED

Flag field that indicates whether the certificate is marked as trusted, and thus whether it is used. This field is only present for profiles in the DIGTCERT class. It is an interpretation of the UACC field.

CERTLABL

Repeat field that contains the list of labels issued to digital certificates associated with the user ID. This field is found in the USER class as part of the BASE segment and in the DIGTRING general resource class as part of the CERTDATA segment. The repeat count is stored in the CERTCT field.

CERTLSER

Contains the last eight bytes of the last certificate that was signed with this key. This field can be found in the CERTDATA segment of the DIGTCERT general resource class.

CERTNAME

Repeat group field that contains a list of digital certificates associated with the user ID or connected to the keyring. This field can be found in the BASE segment of the user profile and the CERTDATA segment of the DIGTRING general

resource class. The repeat count is stored in the CERTCT field. See also CERTIFICATE_ISSUER and CERTIFICATE_SERIAL.

CERTPRVK

Contains the private key for this user, and is therefore considered highly confidential. The value is not shown on any display or list and is stored in any unload file as *****. This field is found on user profiles and is part of the BASE segment. This field can only be used in SELECT or EXCLUDE processing with the EXISTS or MISSING keyword.

CERTPRVS

Contains the size, in bits, of the private key, stored in this digital certificate. This field is only present in the CERTDATA segment of DIGTCERT general resource class profiles.

CERTPRVT

Contains the type of the private key, stored in this digital certificate. This field is only present in the CERTDATA segment of DIGTCERT general resource class profiles.

CERTPUBK

Contains the public key for this user. This field is found on user profiles and is part of the BASE segment.

CERTSEQN

Contains an internal sequence number that is incremented whenever a certificate for the user is added, deleted or altered. This field is found on user profiles and is part of the BASE segment.

CERTSJDN

Repeat group field that contains the list of the distinguished names of the subjects of associated digital certificates. This field can be found in the BASE segment of the user profile and the CERTDATA segment of DIGTRING general resource class profile.The repeat count is stored in CERTCT.

CERTSTRT

Contains the date and time signifying the start of the validity of this digital certificate. This field can be found in the CERTDATA segment of the DIGTCERT general resource class.

CERTUSAG

Repeat group field that contains the list of USAGEs defined for the associated digital certificates within this keyring. Any of the following values can be returned: PERSONAL, SITE, or CERTAUTH. This field can be found in the CERTDATA segment of DIGTRING general resource class profiles. The repeat count is stored in the CERTCT field.

CFDTYPE

This field can be found in the CFDEF segment in the CFIELD general resource class. Each profile in this class describes a custom field. This field contains the type of data contained by the custom field. Possible values are: *CHAR*, *NUM*, *HEX*, *FLAG*.

CFFIRST

This field can be found in the CFDEF segment in the CFIELD general resource class. Each profile in this class describes a custom field. This field contains

the syntax rules for the first character of a custom field's value. By default this field outputs a four byte character field AN#S. Use overriding format $CFSYN for command generation. In order to select on CFFIRST, you must use the values from the $CFSYN format. Table 392 shows the possible values of this field.

Table 392. Possible values for CFFIRST and CFOTHER fields

$CFSYN Value	Default output format	Description
ALPHA	AN	Alphabetic and national characters
ALPHANUM	AN#	Alphabetic, national characters, and numerics
ANY	AN#S	All characters
NONATABC	A	Alphabetic only
NONATNUM	A #	Alphabetic and numerics
NUMERIC	#	Numerics only

CFHELP

This field can be found in the CFDEF segment in the CFIELD general resource class. Each profile in this class describes a custom field. This field contains the help text displayed by TSO when no, or an invalid value has been entered on the ADDUSER, ALTUSER, ADDGRP, or ALTGRP command.

CFLIST

This field can be found in the CFDEF segment in the CFIELD general resource class. Each profile in this class describes a custom field. This field contains the header text displayed in front of the custom field value in the LISTUSER or LISTGRP command.

CFMIXED

This flag field can be found in the CFDEF segment in the CFIELD general resource class. Each profile in this class describes a custom field. This field indicates whether the value in a character type custom field keeps its case.

CFMNVAL

This numeric field can be found in the CFDEF segment in the CFIELD general resource class. Each profile in this class describes a custom field. This field indicates the minimum value of a numeric type custom field.

CFMXLEN

This numeric field can be found in the CFDEF segment in the CFIELD general resource class. Each profile in this class describes a custom field. This field indicates the maximum length of the custom field's value in number of characters.

CFMXVAL

This numeric field can be found in the CFDEF segment in the CFIELD general resource class. Each profile in this class describes a custom field. This field indicates the maximum value of a numeric type custom field.

CFOTHER

This field can be found in the CFDEF segment in the CFIELD general resource class. Each profile in this class describes a custom field. This field contains the syntax rules for the remainder characters of a custom field's value. By default

this field outputs a four byte character field AN#S. Use overriding format $CFSYN for command generation. In order to select on CFOTHER you must use the values from the $CFSYN format. Table 392 on page 1144 shows the possible values of this field.

CGAUTHDA, CGCREADT, CGDEFDAT

This repeated field lists the date the user was connected to the group. See the CGGRPCT field.

CGAUTHOR, CGOWNER

This repeated field lists the owner of the connect occurrence, for example the user who created it or last changed it to connect occurrence. See the CGGRPCT field.

CGCREADT

This is an alias of CGAUTHDA field.

CGDEFDAT

This is an alias of CGAUTHDA field. (see "CGAUTH").

CGFLAG1

This repeated field indicates whether the user has the ADSP attribute in the connect group entry. See also the CGGRPCT and GRPADSP fields.

CGFLAG2

This repeated field indicates whether the user has the SPECIAL attribute in the connect group entry. See also the CGGRPCT and GRPSPEC fields.

CGFLAG3

This repeated field indicates whether the user has the OPERATIONS attribute in the connect group entry. See also the CGGRPCT and GRPOPER fields.

CGFLAG4

This repeated field indicates whether the user has the REVOKE attribute in the connect group entry. See also the CGGRPCT and GRPREVOKE fields.

CGFLAG5

This repeated field indicates whether the user has the GRPACC attribute in the connect group entry. See also the CGGRPCT and GRPGRPACC fields.

CGGRPAUD

This repeated field indicates whether the user has the group-AUDITOR attribute within the connect group entry. See also the CGGRPCT and GRPAUD fields.

CGGRPCT

This field lists the number of connect group entries. It is only found in user profiles. The connect fields are CGGRPNM, CGAUTHDA, CGAUTHOR, CGLJTIME, CGLJDATE, CGUACC, CGINITCT, CGFLAG1, CGFLAG2, CGFLAG3, CGFLAG4, CGFLAG5, CGNOTUAC, CGGRPAUD, CGREVKDT, and CGRESMDT.

CGGRPNM

This repeated field lists the connect group entry names, in alphabetical order. See the CGGRPCT field.

CGINITCT

This repeated field lists the number of RACINITs issued for the connect group entry. This field is only updated if RACINIT statistics are on (due to SETROPTS INITSTATS). See the CGGRPCT field.

CGLJDATE

This repeated field lists the last RACINIT date for the connect group entry. This field is only updated if RACINIT statistics are on (due to SETROPTS INITSTATS). See the CGGRPCT field.

CGLJTIME

This repeated field is only found in user profiles. It lists the last RACINIT time for the connect group entry and can only be used for output. This field is only updated if RACINIT statistics are on (due to SETROPTS INITSTATS). See also the CGGRPCT and CGLJDATE fields.

CGNOTUAC

This repeated field indicates whether the user is authorized to use a terminal not defined to RACF for the connect group entry. See the CGGRPCT field.

CGOWNER

This is an alias of CGAUTHOR field. (see "CGAUTHOR" on page 1145).

CGRESMDT

This repeated field lists the resume date for the connect group entry. See the CGGRPCT field.

CGREVKDT

This repeated field lists the revoke date for the connect group entry. See the CGGRPCT field.

CGUACC

This repeated field lists the universal access for the connect group entry. See the CGGRPCT field for connect information; see the GRPADSP field for the meaning of the CGUACC field.

CHILDN

This field is found in the ROLE class and is part of the TME segment. It is the count of child roles of the role. These child roles are listed in CHILDREN.

CHILDREN

This field is found in the ROLE class as part of the TME segment. It is a repeat group field; the repeat count is stored in the CHILDN field. It contains the list of child roles of the role.

CHECKADDRS, CHKADDRS

This flag field is found in the KERB segment of RACF profiles in the REALM class. The field specifies whether the Kerberos server validates network addresses in encrypted tickets as part of ticket validation processing. The flag is used for the KERBDFLT profile only; this profile is created in the REALM class and defines the local realm.

CICS

This field can only be used for SELECT/EXCLUDE processing. It selects CICS segments.

CICS_RSLKEY

This pseudofield contains all the values of the repeated field RSLKEY, and is, like its source field, present in the CICS segment of user profiles. It is meant for easy administration of the Resource Security Level Keys assigned. It can also be printed with the overriding format SLKEY_COMPACT, which shows all Security Level Keys in ranges (*10:25*, for example).

CICS_TSLKEY

This pseudofield contains all the values of the repeated field TSLKEY, and is, like its source field, present in the CICS segment of user profiles. It is meant for easy administration of the Transaction Security Level Keys assigned. It can also be printed with the overriding format SLKEY_COMPACT, which show all Security Level Keys in ranges (*10:25* for example).

CKGAUTH

Variable defined in C2RXDEF1 that contains the CKGRACF authority requirement (`SINGLE`, `DUAL`, or `TRIPLE`) of a profile, if set.

CKGAUTHOR

This field is derived from the USR field and contains the `userid` of the user who requested a CKGRACF queued command. It is repeated for each queued command stored in the profile; undefined if the profile does not contain queued commands.

CKGCHGDATE

This field is derived from the USR field and contains the date a queued command was last changed. It is repeated for each queued command stored in the profile; undefined if the profile does not contain queued commands.

CKGEVENTS

Variable defined in C2RXDEF1 that contains the CKGRACF schedules for a profile.

CKGEXPIRY

This field is derived from the USR field and contains the first date on which any of the queued commands expires. Each queued command has one expiration date. This field shows the value of the earliest expiration date in the queue. Undefined if the profile does not contain queued commands.

CKGMULTI

This field is derived from the USR field and contains the multiple-authority setting; can be SINGLE, DUAL, or TRIPLE if set; otherwise undefined.

CKGOTHER

Variable defined in C2RXDEF1 that contains the `CKGRACF` entries that are not contained in `CKGAUTH` (authority requirement), `CKGEVENTS` (schedules), `CMDSEXEC`, `CMDSINACT`, and `CMDSPEND` (executed, rejected, and pending queued commands). Together these are the complement of `USERDATA` (non-CKGRACF entries) with respect to `USR` (all user data entries).

CKGREFRESH

This field is derived from the USR field and contains the date after which a CKGRACF REFRESH command is required; undefined if the profile does not contain scheduled revoke/resume actions or queued commands.

CKGREQUEST

This field is derived from the USR field and contains the date a queued command was requested. The value is repeated for each queued command stored in the profile. If the profile does not contain queued commands, the value is undefined.

CKGSCHEDULE, CKGSCHED

This field is derived from the USR field and contains the schedule name of a scheduled revoke/resume action. It is repeated for each scheduled action stored in the profile; undefined if the profile does not contain scheduled actions.

CKGSTATUS

This field is derived from the USR field and contains the current status of a queued command. It is repeated for each queued command stored in the profile; undefined if the profile does not contain queued commands. The values are listed in the following table. (The abbreviations used to indicate this status in the output of the USR field.)

Table 393. CKGSTATUS values for queued commands

Value	USR abbreviation
COMPLETE APPROVE	(CA)
COMPLETE DENY	(CD)
COMPLETE HOLD	(CH)
EXPIRE	(E)
PENDING	(P)
PENDING REVERSE	(PR)
REQUEST	(R)
SECOND APPROVE	(SA)
SECOND DENY	(SD)
SECOND HOLD	(SH)
WITHDRAW	(W)
EXECUTED	(X)

CLASS, C

Provides the RACF class, USER, GROUP, DATASET, PROGRAM, ACCTNUM, or GCICSTRN, for example.

When used for SELECT/EXCLUDE processing, the special value GENERAL indicates all kinds of general resource classes. If used in combination with the MATCH or BESTMATCH keyword, the class selection has a special meaning, selecting both a member class and its grouping class.

CLASTYPE

This field is only found in GENERAL profiles. It lists the class number from the Class Descriptor Table (CDT, see the ID field of NEWLIST TYPE=CLASS). This number indicates the class to which the profile belongs, but it is not used by RACF.

CLASS_CASE_ASIS

This is an alias of CDTCASE.

CLASS_DFLTRC

This is an alias of CDTDFTRC.

CLASS_EQUALMAC

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether equal mandatory access checking is performed for resources in this user-defined class. This means that in order to be granted access to a resource, the SECLABEL of the user and the resource must be equivalent (have the same security level and categories). This setting is used only when the SECLABEL class is active. See also CLASS_RVRSMAC and the combination field CDTMAC. The value in this field cannot be changed on an ISPF panel. If you want to permit users to change the value, use the CDTMAC field.

CLASS_GENLIST_ALLOWED

This is an alias of CDTGENL.

CLASS_MAXLEN

This is an alias of CDTMAXLX.

CLASS_MAXLEN_ENTITY

This is an alias of CDTMAXLN.

CLASS_OPER

This is an alias of CDTOPER.

CLASS_POSIT

This is an alias of CDTPOSIT.

CLASS_QUAL

This is an alias of CDTKEYQL.

CLASS_RACLIST_ALLOWED

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether the user-defined class might be RACLISTed by issuing the SETROPTS RACLIST command. When a class is RACLISTed, both discrete and generic profiles are loaded into storage that is shared between all address spaces. See also CLASS_RACLREQ, and the combination field CDTRACL. The value in this field cannot be modified from an ISPF panel. If you want to permit users to change the value, use the CDTRACL field.

CLASS_RACLREQ

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether the user-defined class must be RACLISTed. When a class is RACLISTed, both generic and discrete profiles are loaded into storage that is shared between all address spaces. See also CLASS_RACLIST_ALLOWED, and the combination field CDTRACL CDTRACL.

CLASS_RVRSMAC

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether reverse mandatory access checking is performed for resources in the

user-defined class. This means that the SECLABEL of the resource must dominate the SECLABEL of the user. This setting is used only when the SECLABEL class is active. See also CLASS_EQUALMAC, and the combination field CDTMAC. The value in this field cannot be modified from an ISPF panel. If you want to permit users to change the value, use the CDTMAC field.

CLASS_SECLABEL

This is an alias of CDTSLREQ.

CLASS_SIGNAL

This is an alias of CDTSIGL.

CLASS_SYN1ALP

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether the first character of a profile in the user-defined class might be alphabetical. Combine this flag with the CLASS_SYN1NAT, CLASS_SYN1NUM, and CLASS_SYN1SPE flags to determine all legal first characters. The value in this field cannot be changed from an ISPF panel. If you want to permit users to change the value, use the combination field CDTFIRST.

CLASS_SYN1NAT

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether the first character of a profile in the user-defined class might be a national character (#, @, and $). Combine this flag with the CLASS_SYN1ALP, CLASS_SYN1NUM, and CLASS_SYN1SPE flags to determine all legal first characters. This value in this field cannot be changed from an ISPF panel. If you want to permit users to change the value, use the CDTFIRST field. CDTRACL

CLASS_SYN1NUM

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether the first character of a profile in the user-defined class can be a numeric character. Combine this flag with the CLASS_SYN1ALP, CLASS_SYN1NAT, and CLASS_SYN1SPE flags to determine all legal first characters. See also the combination field CDTFIRST. The value in this field cannot be changed from an ISPF panel. If you want to permit users to change the value, use the combination CDTFIRST field.

CLASS_SYN1RAW

This is an alias of CDTFIRST.

CLASS_SYN1SPE

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether the first character of a profile in the user-defined class can be a special character (any character other than alphabetical, numerical, national, blank, comma, parenthesis or semicolon). Combine this flag with the CLASS_SYN1ALP, CLASS_SYN1NAT, and CLASS_SYN1NUM flags to

determine all legal first characters. The value in this field cannot be changed from an ISPF panel. If you want to permit users to change the value, use the combination field CDTFIRST.

CLASS_SYNRALP

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether all characters other than the first character of a profile in the user-defined class can be alphabetical. Combine this flag with the CLASS_SYNRNAT, CLASS_SYNRNUM, and CLASS_SYNRSPE flags to determine all legal remainder characters. The value in this field cannot be changed from an ISPF panel. If you want to permit users to change the value, use the combination field CDTOTHER.

CLASS_SYNRNAT

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class; see "CLASS: RACF Class Descriptor Table" on page 989. This field indicates whether all characters other than the first character of a profile in the user-defined class can be a national character (#, @, and $). Combine this flag with the CLASS_SYNRALP, CLASS_SYNRNUM, and CLASS_SYNRSPE flags to determine all legal remainder characters. The value in this field cannot be changed from an ISPF panel. If you want to permit users to change the value, use the combination field CDTOTHER.

CLASS_SYNRNUM

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class. This field indicates whether all characters other than the first character of a profile in the user-defined class can be a numeric character (0-9). Combine this flag with the CLASS_SYNRALP, CLASS_SYNRNAT, and CLASS_SYNRSPE flags to determine all legal remainder characters. The value in this field cannot be changed from an ISPF panel. If you want to permit users to change the value, use the combination field CDTOTHER.

CLASS_SYNRRAW

This is an alias of CDTOTHER.

CLASS_SYNRSPE

This flag field can be found in the CDTINFO segment in the CDT general resource class. Each profile in this class describes a user-defined class. This field indicates whether all characters other than the first character of a profile in the user-defined class can be a special character (any character other than alphabetical, numerical, national, blank, comma, parenthesis, or semicolon). Combine this flag with the CLASS_SYNRALP, CLASS_SYNRNAT, and CLASS_SYNRNUM flags to determine all legal remainder characters. The value in this field cannot be changed from an ISPF panel. If you want to permit users to change the value, use the combination field CDTOTHER.

CLASS_UACC

This is an alias of CDTUACC.

CLASS_XGROUP

This is an alias of CDTGROUP.

CLASS_XMEMBER

This is an alias of CDTMEMBR.

CLCNT

This field indicates the number of classes for which the user has the CLAUTH attribute. It is only found in user profiles. The CLNAME field lists the classes.

CLNAME

Repeated field that lists the classes in which the user is permitted to define profiles. That is classes for which the user has the CLAUTH attribute. This field is only found in user profiles. Each entry is 8 characters. The CLCNT field lists the number of classes.

CMDSEXEC

Variable defined in C2RXDEF1 that contains the CKGRACF queued commands that have been performed. They are kept according to the CKGRACF audit period. See also CMDSINACT and CMDSPEND.

CMDSINACT

Variable defined in C2RXDEF1 that contains the CKGRACF queued command requests that have been rejected. These commands were withdrawn, have expired, or were denied by a responsible administrator. They are kept according to the CKGRACF audit period. See also CMDSEXEC.

CMDSPEND

Variable defined in C2RXDEF1 that contains commands pending in the CKGRACF execution queue, both Pending (P) and Pending Reverse (PR). See also CMDSEXEC and CMDSINACT.

CNGAUTH

Variable defined in C2RXDEF1 that is equivalent to CKGAUTH.

CNGAUTHOR

This is an alias of CKGAUTHOR.

CNGCHGDATE

This is an alias of CKGCHGDATE.

CNGEVENTS

Variable defined in C2RXDEF1 that is equivalent to CKGEVENTS.

CNGEXPIRY

This is an alias of CKGEXPIRY.

CNGMULTI

This is an alias of CKGMULTI.

CNGOTHER

Variable defined in C2RXDEF1 that is equivalent to CKGOTHER.

CNGREFRESH

This is an alias of CKGREFRESH.

CNGREQUEST

This is an alias of CKGREQUEST.

CNGSCHEDULE, CNGSCHED

This is an alias of CKGSCHEDULE.

CNGSTATUS

This is an alias of CKGSTATUS.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

CONCERN

This is an alias of the AUDITCONCERN field.

CONGRPCT

This field indicates the number of groups to which the user is connected. It is only found in user profiles. The CONGRPNM field lists the groups.

CONGRPNM

This is a repeated field listing the groups to which the user is connected, in chronological order (for example, in the order in which the user was connected to each group). This field is only found in user profiles. The CONGRPCT field lists the number of groups.

Note: This field should *not* be combined with the CG... fields for listing group occurrences. All CG... fields are sorted in alphabetical order, and the CONGRPNM field is sorted in chronological order. Use the CGGRPNM field instead.

CONNECT

This field shows an integrated display of the connect attributes Authority, Revoke status, Special, Operations, Audit, ADSP, Group-access, UACC, Revoke date, and Resume date. It can only be used for output on the DISPLAY, SORTLIST, and (D)SUMMARY commands. It must be specified based on an indirect reference to USERID when displaying a group profile, and based on an indirect reference to CONGRPNM or CGGRPNM when displaying a user profile. This field combines information from group profiles with information from user profiles, and interprets the revoke/resume dates and flag against the date of RACF unload (or the current date, if not unloaded). When running on z/OS 1.7 or higher, revoke/resume dates are always shown, if present. In earlier releases, these dates were only shown for future dates. Be aware that connect information is needed, so displaying this field works best if specified in the scope of a NEWLIST while there are no outer selections.

CONNECT_COUNT

This pseudo-field is only found in GROUP BASE segments and contains the number of users connected to the group. Unlike the ACLCNT field it shows the total count of all connected users even for UNIVERSAL groups. This value can only be calculated when a full database read has been done. To force a full database read when not using an UNLOAD you can specify the UNIVERSAL

modifier on this field. This field can only be used on the SORTLIST, DISPLAY and (D)SUMMARY commands, and not on SELECT and EXCLUDE.

CONNECTS

Shows an integrated display with the following information about connect attributes: authority level, Revoke status, Special, Operations, and Auditor attributes, ADSP value, Group-access and UACC list, Revoke date, and Resume date. The value in the revoke date field can be modified by typing a date (*ddmmmyyyy*) or removed by typing the text *NOREVOKE*. The value in the Resume date field can be modified by typing a date (*ddmmmyyyy*) or removed by typing the text *NORESUME* .

For user profiles, it shows connected groups and the connect attributes; for group profiles, it shows connected users and connect attributes. If no connect authority is specified on the group profile, a value of USE is assumed. This field combines information from group profiles with information from user profiles, and interprets the revoke/resume dates and flag against the date of the RACF unload (or the current date, if not unloaded). For z/OS 1.7 and later, revoke/resume dates are always shown, if present. In earlier releases, these dates were only shown when if they were future dates. Be aware that connect information is needed, so displaying this field works best if specified in the scope of a NEWLIST while there are no outer selections, or with the UNIVERSAL modifier specified to force collection of all relevant data.

The DEFINE SUBSELECT command can be used to select specific repeat group instances for output, only group-SPECIAL connects for example. See "Subselect clauses" on page 755.

To print just the ids, use overriding length 8. To print only specific connect attributes, use a lookup, e.g. CONNECTS:GRPSPEC.

CONSNAME

This field is found in user profiles and is part of the NETVIEW segment. It contains the default MCS console identifier.

CONVSEC

This field is found on the SESSION segment of the APPCLU general resource profile. It specifies the level of security checking performed when conversations are established with the LU protected by this profile.

CPUTIMEMAX

This field is found in user profiles and is part of the OMVS segment. It indicates the maximum CPU time that a process can use, in seconds. It lies between 7 and 2,147,483,647.

CREADATE

This is an alias of AUTHDATE field. (see "AUTHDATE" on page 1135).

CSCNT

This field can be found in the CSDATA segment of user and group profiles. It lists the number of custom field entries. The preferred interface to this field is the CUSTOM_DATA field.

CSFAUSE, ASYMUSAGE

Specifies how an asymmetric key controlled can be used by the general resources profiles in the following classes CSFKEYS, GCSFKEYS, XCSFKEY,and

GXCSFKEY. The field can be found in the ICSF segment that specifies attributes for the keys controlled by these profiles. Table 394 shows the possible field values.

Table 394. ASYMUSAGE field values for use of asymmetric key

ASYMUSAGE value	Default output format	Description
SECUREEXPORT HANDSHAKE	SH	The asymmetric key can be used to import or export symmetric keys (SECUREEXPORT) and to protect communication channels (HANDSHAKE). This is the default value.
NOSECUREEXPORT HANDSHAKE	H	The asymmetric key can only be used to protect communication channels (HANDSHAKE).
SECUREEXPORT NOHANDSHAKE	S	The asymmetric key can only be used to import or export symmetric keys (SECUREEXPORT).
NOSECUREEXPORT NOHANDSHAKE	blank	The asymmetric key cannot be used to import or export symmetric keys (NOSECUREEXPORT) nor to protect communication channels (NOHANDSHAKE) .

Asymmetric key usage values for selection can be (NO)SECUREEXPORT, (NO)HANDSHAKE, or a combination of values as shown in Table 394. You can only modify the CFSAUSE, ASYMUSAGE field indirectly using the HANDSHAKE and SECUREEXPORT fields. You can use overriding format `$AsymKeyUsage` for command generation. (See "Specifying syntax for RACF command input" on page 810.)

CSFSCPW, SYMCPACFWRAP

Indicates if the symmetric keys covered by this profile can be rewrapped. This value comes from the ICSF segment which specifies attributes for the keys controlled by general resources profiles in the `CSFKEYS, GCSFKEYS`.

CSFSEXP, SYMEXPORTABLE

Indicates whether the symmetric keys covered by this profile can be exported. This value comes from the ICSF segment which specifies attributes for the keys controlled by general resources profiles in classes CSFKEYS, GCSFKEYS, XCSFKEY,and GXCSFKEY. Table 395 shows the possible values of this field.

Table 395. SYMEXPORTABLE field values

SYMEXPORTABLE value	Default output format	Description
BYANY	ANY	The symmetric key can be exported without restriction. The SYMEXPORTCERTS and SYMEXPORTKEYS fields are ignored; this is the default.
BYLIST	LIST	The symmetric key can only be exported by a public key which is identified in the SYMEXPORTCERTS or SYMEXPORTKEYS field. If neither field exists, then the key cannot be exported. This is equivalent to the BYNONE option.
BYNONE	NONE	The symmetric key cannot be exported. The SYMEXPORTCERTS and SYMEXPORTKEYS fields are ignored.

Symmetric key exportable values for selection can be (BY)ANY, (BY)LIST, or (BY)NONE. You can use overriding format $SymKeyExp for command generation.

CSFSCLBS, SYMEXPORTCERTS

This repeat group field can be found in the ICSF segment which specifies attributes for the keys controlled by general resources profiles in classes CSFKEYS, GCSFKEYS, XCSFKEY, and GXCSFKEY. In particular, this field specifies a list of digital certificate labels that can be used to export the symmetric keys controlled by these profiles. The certificate must exist within the SAF key ring or PKCS#11 token identified in an ICSF configuration setting. Its default output length is 73 characters. This field can be modified. See *Cryptographic Services ICSF Administrator's Guide* for more information.

CSFSCLCT

This field can be found in the ICSF segment which specifies attributes for the keys controlled by general resources profiles in classes CSFKEYS, GCSFKEYS, XCSFKEY,and GXCSFKEY. In particular, this field denotes the number of certificate labels that can be used to export the symmetric keys controlled by these profiles. See also the CSFSCLBS field.

CSFSKLBS, SYMEXPORTKEYS

This repeat group field can be found in the ICSF segment that specifies attributes for the keys controlled by general resource profiles in classes CSFKEYS, GCSFKEYS, XCSFKEY,and GXCSFKEY. This field specifies a complete list of the ICSF key labels pertaining to public keys that can be used to export the symmetric keys covered by these profiles. The label name must not exceed 64 characters, which in effect is its default output length. The first character must be alphabetic or national (@, #, and $). Subsequent characters can be alphanumeric (including the national characters) or a period. This field can be modified. See *Cryptographic Services ICSF Administrator's Guide* for more information.

CSFSKLCT

This field can be found in the ICSF segment which specifies attributes for the keys controlled by general resources profiles in classes CSFKEYS, GCSFKEYS, XCSFKEY,and GXCSFKEY. In particular, this field denotes the number of PKDS labels which can be used to export the symmetric keys covered by these profiles. See "CSFSKLBS" for more information.

CSKEY

This repeated field can be found in the CSDATA segment of user and group profiles. Each entry contains a custom field's name. The preferred interface for reporting this information is the CUSTOM_DATA field, or use the content of CSKEY directly as a field name.

CSTYPE

This repeated field can be found in the CSDATA segment of user and group profiles. Each entry contains a custom field's type.

CSVALUE

This repeated field can be found in the CSDATA segment of user and group profiles. Each entry contains a custom field's value. The preferred interface to this field is to use the CSKEY content as a field name directly or use the CUSTOM_DATA field.

CTL

This field is found in user profiles and is part of the NETVIEW segment. It contains a flag that specifies whether a security check should be performed for this NetView operator for a span or a cross-domain logon. This field can have the values **General**, **Global**, and **Specific**.

CURKEY

This field can be found in the KERB segment for both the USER and the REALM General Resource class. It contains the current key for the user or realm in encrypted form. This field is removed from any UNLOAD made.

CURKEYV

This field can be found in the KERB segment for both the USER and the REALM General Resource class. It contains the version number of the current key for the user or realm.

CUSTOM_DATA

Repeated field that contains the custom list header for the field followed by the value of the field. This field can be found in the CSDATA segment of user and group profiles. The field can only be specified on the following commands: DISPLAY, DSUMMARY, SORT, SORTLIST, and SUMMARY.

You can use the DEFINE SUBSELECT command to display only selected repeat group entries. See "Subselect clauses" on page 755. You can use the SELECT CUSTOM_DATA(...) command to select on specific combinations of values per repeat group entry. See "SELECT/EXCLUDE CUSTOM_DATA(...)" on page 890.

To only print the value of the CUSTOM_DATA field, use the CSVALUE format. To print the name of the field followed by its value in parenthesis, use the $CUSTOM_DATA format. This latter format can be used for command generation.Beginning with zSecure V1R11, the output for the CUSTOM_DATA field can only be formatted using the WRAP format field if the MODIFIABLE attribute for the CUSTOM_DATA field is turned off. The WRAP and MODIFIABLE options can be specified using the FIELD NEWLIST. See "FIELD: Field Properties per NEWLIST type" on page 1034. If the WRAP modifier is specified for a new field, the MODIFIABLE attribute is automatically turned off.

DATA

This is an alias of INSTDATA (see "INSTDATA, DATA" on page 1172).

DATAAPPL

For user or group profiles, this field provides the DPF-data application in DFP segment.

DATACLAS

For user or group profiles, this field provides DFP-data class in the DFP segment.

DB

This field contains the three-digit sequence number of the data set in the RACF database originally containing the profile. The data sets making up the RACF databases, their sequence numbers, and the profile key ranges can be displayed using the NEWLIST TYPE=RRNG.

DCE

This field can only be used for SELECT or EXCLUDE processing. It selects DCE segments.

DCEENCRY

This field is found in the DCE segment of the user profile. It contains the DCE password mask/encrypt key.

DCEFLAGS

This field is found on the DCE segment of the user profile. It specifies whether z/OS UNIX DCE automatically attempts to sign on this user to z/OS UNIX DCE.

DCENAME

This field is found on the DCE segment of the user profile. It contains the DCE principal name of this user.

DEFDATE

This is an alias of AUTHDATE (see "AUTHDATE" on page 1135).

DEFTKTLF

This field can be found in the KERB segment for the REALM General Resource class. It contains the default ticket life in seconds that is granted when generating a ticket for the target system.

DEPTH

This field can only be used for output processing, on a SORTLIST, DISPLAY or (D)SUMMARY command. It is defined for group profiles and indicates the depth of the group within the group tree. It is mainly of use to sort commands that apply to several groups in succession, or as INDENT parameter in a group-tree display.

DEVTYP

This field is found in DATASET profiles. It indicates the device type on which the data set resides. Not specified for generic profiles and some non-VSAM discrete profile types. The default output format is a hexadecimal representation of a unit type.

DEVTYPX, UNIT

This text field is found in DATASET profiles. It contains the name of the device type on which the data set resides. Not specified for generic profiles and some non-VSAM discrete profile types.

The UNIT field name can only be used for SELECT/EXCLUDE processing.

DFLTGRP

The default connect group of a user. This field is only found in user profiles.

DFP

This field can only be used for SELECT/EXCLUDE processing. It selects DFP segments.

DIDCT

This field is found in IDIDMAP profiles. It contains the number of identity mappings in the profile. The distributed identity given by each DIDRNAME

11. For additional information on distributed identity filters, distributed identity mapping, and IDIDMAP profiles, see the *Security Server RACF Security Administrator's Guide* for z/OS Version 1 Release 11 or later.

(registry) and the KEY (identity filter, which can be in X.500 format) is mapped to the RACF userid in each corresponding DIDUSER. See the DIDUSER the field.

For additional information on distributed identity filters, distributed identity mapping, and IDIDMAP profiles, see the *Security Server RACF Security Administrator's Guide* for z/OS Version 1 Release 11 or later.

DIDLABL

This repeat group field is found in IDIDMAP profiles. It contains the labels for the identity mappings. The repeat count is contained in the field DIDCT. See the DDIDCT and the DMAPLABL.

For additional information on distributed identity filters, distributed identity mapping, and IDIDMAP profiles, see the *Security Server RACF Security Administrator's Guide* for z/OS Version 1 Release 11 or later.

DIDRNAME

This repeat group field is found in IDIDMAP profiles. It contains the registries for the distributed identities mapped. The repeat count is contained in the field DIDCT. Also, see the RACMAP_REGISTRY and IDIDMAP_CMD_REGISTRY fields.

For additional information on distributed identity filters, distributed identity mapping, and IDIDMAP profiles, see the *Security Server RACF Security Administrator's Guide* for z/OS Version 1 Release 11 or later.

DIDUSER

This repeat group field is found in IDIDMAP profiles. It contains the RACF userids to which the distributed identities are mapped. The repeat count is contained in the field DIDCT. (See "DIDCT" on page 1158.)

For additional information on distributed identity filters, distributed identity mapping, and IDIDMAP profiles, see the *Security Server RACF Security Administrator's Guide* for z/OS Version 1 Release 11 or later.

DIGTCERT_LABEL

This field is only present for digital certificates (for example, profiles in the DIGTCERT class). It contains the certificate label of the certificate and corresponds to the CERTLABL field in USER, DIGTRING and DIGTNMAP profiles. It can be used as an alternative key for most RACDCERT commands. This field cannot be used for SELECT/EXCLUDE processing.

DIGTRING_USERID

For a profile in the DIGTRING class, this field contains the userid the keyring is related to; for other classes it is absent. When present the content of the field is identical to that of the APPLDATA field.

DISCRETE

This field can only be used for SELECT/EXCLUDE processing. It is used to select discrete DATASET and GENERAL profiles. It can be specified as an attribute, for example SELECT DISCRETE. Use the PROFTYPE output field to display the profile type.

DLFDATA

This field can only be used for SELECT/EXCLUDE processing. It selects DLFDATA segments.

DMAPCT

This field is found in the BASE segment of user profiles. It contains the number of identity mappings that map to the RACF userid. The distributed identities are given by each RACMAP_REGISTRY (registry) and DMAPNAME (identity filter, which can be in X.500 format).

For additional information on distributed identity filters, distributed identity mapping, and IDIDMAP profiles, see the *Security Server RACF Security Administrator's Guide* for z/OS Version 1 Release 11 or later.

DMAPLABL

This repeat group field is found in the BASE segment of user profiles. It contains the identity filter (which can be in X.500 format) for the identity mappings to this userid. Together with the userid, the label uniquely identifies a particular identity mapping. The repeat count is contained in the DMAPCT field.

For additional information on distributed identity filters, distributed identity mapping, and IDIDMAP profiles, see the *Security Server RACF Security Administrator's Guide* for z/OS Version 1 Release 11 or later.

DMAPNAME

This repeat group field is found in the BASE segment of user profiles. It contains the identity filter (which can be in X.500 format) for the identity mappings to this userid. The repeat count is contained in the field DMAPCT. See "DMAPCT" on page 1159 and "RACMAP_CMD_FILTER" on page 1193.)

For additional information on distributed identity filters, distributed identity mapping, and IDIDMAP profiles, see the *Security Server RACF Security Administrator's Guide* for z/OS Version 1 Release 11 or later.

DOMAINDN

This field is found on the EIM segment of LDAPBIND and FACILITY class general resource profiles. It specifies the distinguished name of the EIM domain. This field supports the overtype which permits authorized users to change the field value from an ISPF panel.

DOMAINS

This field is found in user profiles and is part of the NETVIEW segment. It is a repeated field; the repeat count is stored in the DOMAINSN field. Each repeat group entry contains the name of a Netview program in another domain; the operator has authority over the Netview programs listed by this field.

DOMAINSN

This field is found in user profiles and is part of the NETVIEW segment. It contains the repeat count for the DOMAINS field.

DOMAP

This field is found in the ICTX segment of IRR.ICTX.DEFAULTS.** profiles in the LDAPBIND general resource class. It specifies whether the Identity Context Extension (ICTX) uses Enterprise Identity Mapping (EIM) services to find a mapping to a z/OS user ID. This field supports the overtype option which permits authorized users to change the value from an ISPF panel.

DPASSWDS

This field is found on the DCE segment of the user profile. It contains the current DCE password.

DSN

This field is equivalent to the KEY and PROFILE fields, but it is only defined for data set profiles. It contains the name of a data set profile.

DSTYPE

This field is found in DATASET BASE segments, and can only be used for output. The following table lists the DSTYPE values and their meaning:

Table 396. DSTYPE values

DSTYPE value	Meaning
MODEL	Model profile
TAPE	Tape data set
VSAM	VSAM
(blank)	None of the above

For SELECT/EXCLUDE processing, use the MODEL, TAPE, and VSAM fields.

EIM

This field can only be used for SELECT/EXCLUDE processing. It selects EIM segments.

ENCRYPT

This field can be found in the KERB segment for both the USER and the REALM General Resource class. It contains the encryption types that can be used when establishing a connection.

ENCTYPE

This field can be found in the KERB segment for both the USER and the REALM General Resource class. It contains the encryption type that has been used to establish a connection.

ENTITY

This field is similar to CLASS, but it returns GENERAL for all general resource classes. Meant for use like SUMMARY ENTITY SEGMENT.

ENTYPE

This field can be found in all profile types and indicates the profile entity type. It is a numerical value of up to three digits. The following table lists the entity types defined.

Table 397. Entity type definitions

ENTYPE value	Profile type
1	GROUP
2	USER
3	CONNECT
4	DATASET
5	GENERAL

ERASE

This field is only found in DATASET BASE segments. It indicates whether the erase-on-scratch flag is set. It can be specified as an attribute, e.g., .SELECT ERASE. Its opposite for the purpose of SELECT/EXCLUDE processing is NOERASE.

Note that a data set profile's erase-on-scratch setting is only honored if erase-on-scratch is in effect (due to SETROPTS ERASE). This is indicated by the ERASEONSCRATCH field of NEWLIST TYPE=SYSTEM.

FAILLOAD

FAILLOAD is found in GENERAL resource profiles and is part of the SIGVER segment.

The value in this field indicates what action the system loader is to take when signature verification fails. This field can be based on the value of the field or the presence of the field. The following values can be displayed. The field can be selected based on the value in the field or the presence of the field.

Table 398. Fail reasons

Value	Description
ANYBAD	Specifies that the program fails to load when a signature verification failure occurs, regardless of the cause.
BADSIGONLY	Specifies that the program fails to load only when the signature verification failure is caused by an incorrect digital signature.
NEVER	Specifies that the program never fails to load because a signature verification failure is detected.

FILEPROCMAX

This field is found in user profiles and is part of the OMVS segment. It indicates the maximum number of files that this user is permitted to have open at any given time. It lies between 3 and 262,143 (pre-z/OS V1R7) or 524,288 (z/OS V1R7 and up).

FILTER, MASK

This field can only be used for SELECT/EXCLUDE processing. It is used to search for the profile key using a pattern match. For example, FILTER=SYS1.** matches all profile keys that start with SYS1. To search for an exact profile key, use the KEY field instead. To search for all profiles that could match a given resource name, use the MATCH field instead.

A mask for the profile key. Use %, *, and .** (enhanced generic naming). The filter is *always* interpreted as enhanced generic, independent of the RACF database setting for EGN. If you specify a generic profile key here, this matches generic profiles and discretes that are covered by this name.

The meaning of a single * depends on the entity type. For data sets only, it matches a qualifier with a maximum of 8 characters. Note that for general resource profiles, the * at the end of FILTER selects only a single qualifier (while in RACF it means any number of qualifiers).

FILTER_ISSUERDN

This pseudofield exists only for profiles in the DIGTNMAP class and contains the description for the filter of the issuer's distinguished name. See also FILTER_SUBJECTDN and FLTRNAME.

FILTERCT

This pseudofield exists only for profiles in the DIGTNMAP class and contains the description for the filter of the subject's distinguished name. See also FILTER_ISSUERDN and FLTRNAME.

FILTERCT

This field can be found in the BASE segment of a general resource profile in the DIGTNMAP class. It is the count of digital certificate filters that map to the key of this profile.

FLAG1

For user profiles, this flag byte field indicates the ADSP attribute. See the ADSP field. For DATASET profiles, this flag indicates a group data set. See the GROUPDSN field.

FLAG2

For user profiles, this flag byte field indicates the SPECIAL attribute. See the SPECIAL field.

FLAG3

For user profiles, flag byte field that indicates the OPERATIONS attribute. See the OPER field.

FLAG4

For user profiles, flag byte field that indicates the REVOKE attribute. See the REVOKE field.

FLAG5

For user profiles, flag byte field that indicates the GRPACC attribute. See the GRPACC field.

FLAG6

For user profiles, flag byte field that indicates the AUDITOR attribute, see the AUDITOR field.

FLAG7

This flag field is found in the BASE segment of user profiles. It contains password, protected and password phrase flag bits. By default, this flag byte is printed hexadecimal. See also fields HAS_PASSWORD, PROTECTED, and HAS_PHRASE.

FLAG8

For user profiles, this flag byte field indicates if the user requires an OID card to logon. See the OIDCARD field.

FLAG9

For user profiles, this flag byte field indicates if the user has the RESTRICTED attribute, see the RESTRICTED field.

FLAGPRIV

This field is found in STARTED profiles and is part of the STDATA segment. It indicates whether a started procedure matching the profile should run privileged (FLAGPRIV=YES) or not (FLAGPRIV=NO). If the FLAGPRIV field is set to YES, indicating the started procedure should run privileged, the FLAGTRUS flag is ignored.

FLAGTRAC

This field is found in STARTED profiles and is part of the STDATA segment. It indicates whether a started procedure matching the profile should be traced

(FLAGTRAC=YES) or not (FLAGTRAC=NO). If the started procedure is traced, RACF issues message IRR812I to indicate the profile and started procedure used.

FLAGTRUS

This field is found in STARTED profiles and is part of the STDATA segment. It indicates whether a started procedure matching the profile should run trusted (FLAGTRUS=YES) or not (FLAGTRUS=NO). If the FLAGPRIV field is set to YES, indicating the started procedure should run privileged, the FLAGTRUS flag is ignored.

FLDCNT

For all profile types: field counting the number of FLDNAME, FLDVALUE and FLDFLAG fields.

FLDFLAG

For all profile types: reserved field. This repeated field can be combined with the FLDVALUE and FLDNAME fields. The count is listed in the FLDCNT field.

This field indicates the erase-on-scratch flag for DATASET profiles, if the corresponding FLDNAME field is set to EOSFLAG.

FLDNAME

For all profile types: reserved field. This repeated field can be combined with the FLDVALUE and FLDFLAG fields. The count is listed in the FLDCNT field.

For DATASET profiles: If this field is set to EOSFLAG, then FLDFLAG is the erase-on-scratch flag. This setting is easier to display with the ERASE field.

FLDVALUE

For all profile types: reserved field. This repeated field can be combined with the FLDNAME and FLDFLAG fields. The count is listed in the FLDCNT field.

FLTRLABL

This field is found in the BASE segment of a general resource profile in the DIGTNMAP class. It is a repeat group field; its count is stored in the FILTERCT field. It shows the list of labels describing the digital certificate filters that map to the key of this profile.

FLTRNAME

This field is found in the BASE segment of a general resource profile in the DIGTNMAP class. It is a repeat group field; its count is stored in the FILTERCT field. It contains a list of descriptions of the digital certificate filters that map to the key of this profile. This description contains a filter for the issuer's distinguished name and one for the subject's distinguished name, separated by a ¢. See also FILTER_ISSUERDN and FILTER_SUBJECTDN.

FLTRSTAT

This field is found in the BASE segment of a general resource profile in the DIGTNMAP class. It is a repeat group field; its count is stored in the FILTERCT field. It contains the status of the digital certificate filters that map to the key of this profile, for example whether they are TRUST or NOTRUST.

FLTRUSER

This field is found in the BASE segment of a general resource profile in the DIGTNMAP class. It is a repeat group field that contains a list of the user IDs specifying the RACF user ID that the digital certificate filters described in this

profile map to. This field can also contain the generic key description for a profile in the DIGTCRIT class for filters that can map to multiple user IDs.

The repeat count for the FLTRUSER field is stored in the FILTERCT field.

FSROOT

This field is found on the OVM segment of the user profile. It contains the user's OpenExtensions file system root directory.

GAUDIT

Flag field that indicates the global audit flags set by the auditor. This field is found in DATASET and general resource profiles. These flags determine whether to log successful and failed accesses.

The global audit qualifiers determine the level from which accesses are logged. These values are listed in the GAUDITQF and GAUDITQS fields. See also the AUDIT field, which lists the audit flags set by the user. The easiest way to print the global audit information is through the "GAUDITLVL" on page 1166 field, "GAUDITS" on page 1167, or "GAUDITF" fields.

Use the GAUDITLVL field if you want to permit authorized users to change audit field values on the display panels.

Table 399 lists the GAUDIT values and their meaning.

Table 399. GAUDIT values and descriptions

GAUDIT value	Meaning
ALL	Audit successful accesses from GAUDITQS and failed accesses from GAUDITQF.
SUCCESS	Audit successful accesses from GAUDITQS.
FAILURE	Audit failed accesses from GAUDITQF.
NONE	No auditing.

The audit qualifiers determine the level from which accesses are logged. These qualifiers are listed in the "GAUDITQF" on page 1166 and "GAUDITQS" on page 1166 fields (in non-interpreted form) and in the "GAUDITF" and "GAUDITS" on page 1167 fields (in common form).

The GAUDITQF and GAUDITQF fields are unpredictable when failure or success auditing has not been specified. For normal situations use GAUDITLVL, GAUDITS or GAUDITF. Use the GAUDITLVL field if you want to permit authorized users to change audit field values on the display panels.

GAUDITF

This derived field contains the global audit failure level. The value is based on the raw GAUDIT and GAUDITQF fields. The values it can have are listed in the Table 400. The blank (*X'FF'*) value means that global failure auditing is not active. This field is designed for use in SELECT statements.

Use the "GAUDITLVL" on page 1166 field if you want to permit authorized users to change audit field values on the display panels.

Table 400. GAUDITF values and descriptions

GAUDITF value	Internal value (hex)
ALTER	03
CONTROL	02

Table 400. GAUDITF values and descriptions (continued)

GAUDITF value	Internal value (hex)
UPDATE	01
READ	00
(blank)	FF

GAUDITLVL

This field can only be used for output. It contains the global audit level (both successes and failures) in a three-character format: a success level, a blank, and a failure level. The audit levels can have the blank values (not set). The following audit levels can be returned:

- **R** (Read)
- **U** (Update)
- **C** (Control)
- **A** (Alter)

The GAUDITLVL field is the only modifiable global audit field. Use this field if you want to permit authorized users to change audit field values on the display panels.

GAUDITQF

Flag field that indicates the global audit failure qualifier. This field is found in DATASET and general resource profiles and indicates the global audit failure qualifier. If the GAUDIT field is set to *ALL* or *FAILURE*, all failed accesses with intended access equal or higher than this field are logged.

The GAUDITQF field is unpredictable when failure auditing has not been specified. Use the "GAUDITF" on page 1165 field instead. Use the "GAUDITLVL" field if you want to permit authorized users to change audit field values on the display panels.

Table 401 lists the GAUDITQF values.

Table 401. GAUDITQF values

GAUDITQF value	Internal value (hex)
ALTER	03
CONTROL	02
UPDATE	01
READ	00
NONE	FF

GAUDITQS

Flag field that indicates the global audit success qualifier. This field is found in DATASET and general resource profiles.

If the GAUDIT field is set to *ALL* or *SUCCESS*, all successful accesses with intended access equal or higher than this field are logged.

The GAUDITQS field is unpredictable when success auditing has not been specified. Use "GAUDITS" on page 1167 instead.

Use the "GAUDITLVL" field if you want to permit authorized users to change audit field values on the display panels.

The following table lists the GAUDITQS values:

Table 402. GAUDITQS values

GAUDITQS value	Internal value (hex)
ALTER	03
CONTROL	02
UPDATE	01
READ	00
NONE	FF

GAUDITS

This derived field contains the global audit success level. The value is based on the raw GAUDIT and GAUDITQS fields. The values it can have are listed in Table 403. The blank (*X'FF'*) value means that global success auditing is not active. This field is designed for use in SELECT statements.

Use the "GAUDITLVL" on page 1166 field if you want to permit authorized users to change audit field values on the display panels.

Table 403. GAUDITS values

GAUDITS value	Internal value (hex)
ALTER	03
CONTROL	02
UPDATE	01
READ	00
(blank)	FF

GENERIC

This field indicates whether the profile is generic. It can be used to select generic DATASET and GENERAL profiles. It can be specified as an attribute, for example SELECT GENERIC. When used for output, it contains the string 'GENERIC' if the profile was generic, and is blank otherwise.

GID

This field is found in group profiles and is part of the OMVS segment. It indicates the numerical group id used for z/OS UNIX. If the overtype option is active, you can suffix the number with an S–*1001S* for example), so the SHARED command keyword is added. You can also specify AUTO, which results in addition of the AUTOGID command keyword. The SHARED and AUTOGID command keywords are available in z/OS 1.4. or with APAR OW52135.

GROUPADSP

This is an alias of GRPADSP field.

GROUPAUDIT

This is an alias of GRPAUD field.

GROUPAUDITOR

This is an alias of GRPAUD field.

GROUPDS

This is an alias of GROUPDSN field.

GROUPDSN, GROUPDS

This field can only be used for SELECT/EXCLUDE processing. It is an alias for the FLAG1 field found in DATASET BASE segments. It indicates whether the profile covers group data sets, for example, whether the high-level qualifier is a group id. It can be specified as an attribute, for example., SELECT GROUPDSN. Its opposite is USERDSN.

GROUPGRPACC

This is an alias of the GRPGRPACC field.

GROUPN

This field is found in the ROLE class and is part of the TME segment. It is the count of groups associated with the role. These groups are listed in GROUPS.

GROUPNM

This field is found in DATASET profiles. It indicates then-current connect group of the user who created the data set profile.

GROUPOPER

This is an alias of the GRPOPER field.

GROUPOPERATIONS

This is an alias of the GRPOPER field.

GROUPREVOKE

This is an alias of the GRPREVOKE field.

GROUPS

This field is found in the ROLE class as part of the TME segment. It is a repeat group field; the repeat count is stored in the GROUPN field. It contains the list of groups associated with the role.

GROUPSP

This is an alias of the GRPSPEC field.

GROUPSPEC

This is an alias of the GRPSPEC field.

GROUPSPECIAL

This is an alias of the GRPSPEC field.

GRPACC

This field is an alias for the FLAG5 field found in USER BASE segments. It indicates whether the user has the user-GRPACC attribute. It can be specified as an attribute, e.g., SELECT GRPACC. Its opposite for the purpose of SELECT/EXCLUDE processing is NOGRPACC.

If the GRPACC attribute applies, any group DATASET profile created by the user is automatically accessible to all users connected to the group; this is achieved by granting the group UPDATE access on the access list. GRPACC applies if the user has either user-GRPACC or group-GRPACC in the connect group.

On standard userid overviews, this field is usually shown as the second position in a group column headed AG (ADSP and GRPACC).

GRPADSP, GROUPADSP

When used for output, this field is an alias for the CGFLAG1 field found in USER BASE segments. It is repeated for every connect group and indicates whether the user has the group-ADSP attribute in the connect group. The alias GROUPADSP can only be used for SELECT/EXCLUDE processing. It can be specified as an attribute, e.g., SELECT GRPADSP. Its opposite for the purpose of SELECT/EXCLUDE processing is NOGRPADSP.

If the group-ADSP attribute is set for the user's current connect group, any group data set created by the user is protected by a discrete profile with the CGUACC of the current connect group as UACC. Most installations with list-of-groups checking active do not set the group-ADSP attribute, because, counterintuitively, the group-ADSP attribute used is always the one for the current connect group for the user, as opposed to the one for the connect to the group for which the data set is defined. The group-ADSP attribute is only used if system-ADSP is in effect (due to SETROPTS ADSP). This is indicated by the ADSP field of NEWLIST TYPE=SYSTEM.

GRPAUD, GROUPAUDITOR, GROUPAUDIT, GRPAUDITOR

When used for output, this field is an alias for the CGGRPAUD field found in USER BASE segments in the RDS. It is repeated for every connect group and indicates whether the user has the group-AUDITOR attribute in the connect group. The aliases GROUPAUDITOR, GROUPAUDIT and GRPAUDITOR can only be used for SELECT/EXCLUDE processing. It can be specified as an attribute, e.g., SELECT GRPAUD. Its opposite for the purpose of SELECT/EXCLUDE processing is NOGRPAUD. See also the AUDITOR field.

GRPAUDITOR

This is an alias of the GRPAUD field.

GRPGRPAC

This is an alias of GRPGRPACC field.

GRPGRPACC, GROUPGRPACC, GRPGRPAC

This field is an alias for the CGFLAG5 field found in USER BASE segments. It is repeated for every connect group and indicates whether the user has the GRPACC attribute in the connect group entry. (See the CGGRPCT field for a list of all fields in the Connect Group repeat group.) The alias GROUPGRPACC can only be used for SELECT/EXCLUDE processing. It can be specified as an attribute, e.g., SELECT GRPGRPACC. Its opposite for the purpose of SELECT/EXCLUDE processing is NOGRPGRPACC.

If the group-GRPACC attribute is set for the user's current connect group (or the user has the user-GRPACC attribute), any group DATASET profile created by the user is made accessible to all users connected to the group by granting the group UPDATE access on the access list. Note that most installations with list-of-groups checking active do not set the group-GRPACC attribute, because, counterintuitively, the group-GRPACC attribute used is always the one for the current connect group for the user, as opposed to the one for the connect to the group for which the data set is defined.

GRPOP

This is an alias of the GRPOPER field.

GRPOPER, GROUPOPERATIONS, GROUPOPER, GRPOPERATIONS, GRPOP

When used for output, this field is an alias for the CGFLAG3 field found in USER BASE segments. It is repeated for every connect group and indicates whether the user has the group-operations attribute in the connect group. The aliases GROUPOPERATIONS, GROUPOPER, GRPOPERATIONS and GRPOP can only be used for SELECT/EXCLUDE processing. It can be specified as an attribute, e.g., SELECT GRPOPER. Its opposite for the purpose of SELECT/EXCLUDE processing is NOGRPOPER.

GRPOPERATIONS

This is an alias of the GRPOPER field.

GRPREVOK

This is an alias of the GRPREVOKE field.

GRPREVOKE, GROUPREVOKE, GRPREVOK

This field is found in USER BASE segments. It is repeated for every connect group and indicates whether the user has the REVOKE attribute in the connect group entry. It can be specified as an attribute, e.g., SELECT GRPREVOKE. This field takes the revoke date, resume date, and the date of the RACF database unload (or the current date for a database) into account as well as the revoked flag. Use the CGFLAG4 field to select on just the revoke flag. Its opposite for the purpose of SELECT/EXCLUDE processing is NOGRPREVOKE.

GRPSPEC, GROUPSPECIAL, GROUPSPEC, GROUPSP, GRPSPECIAL, GRPSP

When used for output, this field is an alias for the CGFLAG2 field found in USER BASE segments. It is repeated for every connect group and indicates whether the user has the group-special attribute in the connect group. Its main names are GRPSPEC and GRPSPECIAL; the aliases GROUPSPECIAL, GROUPSPEC, GROUPSP and GRPSP can only be used for SELECT/EXCLUDE processing. It can be specified as an attribute, e.g., SELECT GRPSPEC. Its opposite for the purpose of SELECT/EXCLUDE processing is NOGRPSPEC.

HANDSHAKE

This flag field can only be found in the ICSF segment which specifies attributes for the keys controlled by general resources profiles in classes CSFKEYS, GCSFKEYS, XCSFKEY, and GXCSFKEY. It indicates whether the asymmetric key controlled by these profiles can be used to protect communication channels. You can use overriding format $NO for command generation in combination with the ASYMUSAGE keyword. See also “CSFAUSE” on page 1154.

HAS_PASSWORD

This flag field indicates that the user can use a password to logon.

HAS_PHRASE

This flag field indicates that the user can use a password phrase to logon.

On standard userid overviews, this field is usually shown as the second position in a group column headed EPEM (the first E means the user has a password envelope; P means the user has a password phrase; the next E means the user has a password phrase envelope; M means that password checks for the user are case-sensitive).

HAS_PPHENV

This flag field indicates that the user profile contains a password envelope with a form of the password that can be decrypted–that is, a two-way encrypted password.

HAS_PWDENV

This flag field indicates that the user profile contains a password envelope with a form of the password that can be decrypted–that is, a two-way encrypted password.

HEXKEY

The profile name (key) as it exists in the RACF database (for example, generic characters have not been converted). For SELECT/EXCLUDE processing, this can be used to search for specific internal values or specific generic characters.

For output, the default output format is in hexadecimal, with a default length of 88 characters, though a hexadecimal representation can be up to 512 characters long. Use the KEY field for the profile key in external format. The difference between HEXKEY and KEY(HEX,88) is that the former is in RACF internal format and the latter is a hexadecimal representation of the external (human-readable) format.

HOME

This field is found in user profiles and is part of the OMVS segment. It indicates the home directory used for z/OS UNIX. The home directory is a case-sensitive character string of up to 1024 characters.

HOMECELL

This field is found on the DCE segment of the user profile. It contains the home cell for this DCE user.

HOMEUUID

This field is found on the DCE segment of the user profile. It contains the home cell universal unique identifier. The UUID is exactly 36 characters, in the format *nnnnnnnn-nnnn-nnnn-nnnn-nnnnnnnnnnnn* where n is any hexadecimal digit.

IC

This field is found in user profiles and is part of the NETVIEW segment. It contains the Initial Command to be executed by Netview whenever the operator logs on to Netview.

IDIDMAP_CMD_FILTER

Pseudo field found in IDIDMAP profiles that contains the identity filter. This field is intended to be used when generating RACMAP commands in CARLa. It is equivalent to KEY, except that quotes are doubled and `OPTION MY_CCSID=`*`ccsid`* has no influence on the output from this field: Conversion to EBCDIC always uses code page 1047. This field can only be used for output and for selection with EXISTS and MISSING (See “Selecting on field existence” on page 886.)

IDIDMAP_CMD_REGISTRY

Repeat group pseudo field that is equivalent to `DIDRNAME`, except that quotes are doubled and o`OPTION MY_CCSID=`*`ccsid`* has no influence on the output from this field. Conversion to EBCDIC always uses code page 1047. This field is intended to be used when generating RACMAP commands in CARLa. This field can only be used for output and for selection with `EXISTS` and `MISSING` keywords. (See “Selecting on field existence” on page 886.)

IDSTAR

Variable defined in C2RXDEF1 reflects the unconditional access given to `ID(*)`–all `userids` defined to RACF. See UACC for access given to all userids (even undefined ones).

INITCNT

This field is found in group profiles. It has no meaning.

INRANGE

This field is a flag that indicates whether the profile is in the proper RACF data set according to the RACF range table ICHRRNG (loaded from CKFREEZE or live when processing live RACF). This flag is always on unless you have specified SUPPRESS ICHRRNG to include profiles that are not in the proper data set.

INSTDATA, DATA

Installation data. Available in GROUP, USER, DATASET, and GENERAL profiles. Up to 255 characters.

The DATA field name can only be used for SELECT/EXCLUDE processing.

IS_GRPAUDIT, IS_GRPAUD

This pseudo field is only present for user profiles. It indicates whether the user has been connected to any group with the group-auditor attribute.

IS_GRPOPER

This pseudo field is only present for user profiles. It indicates whether the user has been connected to any group with the group-operations attribute.

IS_GRPSPEC, IS_GRPSPECIAL

This pseudo field is only present for user profiles. It indicates whether the user has been connected to any group with the group-special attribute.

JOBNAMES

For GENERAL profiles, this repeated field in the DLFDATA segment contains the `jobname` of the jobs that can access the `DLF` objects protected by the profile. The `jobname` might end in an asterisk (*) to indicate generic job names. The number of job names is listed in the JOBNMCNT field.

JOBNMCNT

For GENERAL profiles, this is a field in the DLFDATA segment containing the number of job names listed in the JOBNAMES field.

KERB

This field can only be used for SELECT/EXCLUDE processing. It selects KERB segments.

KERBNAME

This field can be found in the KERB segment for both the USER and the REALM General Resource class. It contains either the Kerberos principal name for a user, or the unqualified Kerberos realm name for a general resource.

KERBREGISTRY, KERBREG

This field is found in the EIM segment of LDAPBIND and FACILITY class general resource profiles. On the IRR.PROXY.DEFAULTS profile in the FACILITY class it specifies the name of the Kerberos registry in the EIM domain that the system is configured to use. On other profiles it is ignored. This field supports the `overtype` option which permits authorized users to change the field value from an ISPF panel.

KEY, PROFILE

The profile name (key) in external format. That is, generic characters have been converted according to the EGN settings for the site. The length of this field can be up to 255 characters for general resource profiles; data set profiles are limited to 44 characters, and user and group profiles are limited to 8 characters. The default output length is 44 characters. Use the HEXKEY field for the internal format.

KEYDATE

For GENERAL profiles, this field in the SESSION segment lists the last date the session key was changed.

KEYFROM

This field is found in the KERB segment of the user profile. It indicates whether the password or the passphrase was used to generate the Kerberos key.

KEYINTVL

For GENERAL profiles, this field in the SESSION segment lists the number of days before the session key expires.

LANGUAGE

This field can only be used for SELECT/EXCLUDE processing. It selects LANGUAGE segments.

LAST_CONNECT_DATE

This derived field is only defined for user profiles. It contains the last RACINIT date for any group the user is connected to (it is the maximum of the repeated value CGLJDATE). This is usually a better estimate for the last logon date than the LJDATE (which is for instance also affected by ALTUSER), although deleting a user's most recent logon group can set this date back. Note that RACF uses the LJDATE to calculate the user's inactivity interval.

LCHGDAT

This date field is found in DATASET and GENERAL profiles and indicates the date the data set/resource was last updated.

LDAPHOST

This field is found on the PROXY segment of USER and FACILITY class general resource profiles. It specifies the URL of the LDAP server which the z/OS LDAP Server contacts when acting as a proxy on behalf of a requester.

LDAPPROF

This field is found on the EIM segment of the USER class. It specifies the name of a profile in the LDAPBIND class which contains the name of an EIM domain, to be used to establish a connection with the EIM domain.

LEVEL

This numeric field is present in DATASET and general resource profiles. Accepted integer values are 0 - 99. This field is not used by RACF; it is a field that an organization can use for any purpose.

LJDATE

This field, which is only found in user profiles, contains the user's last use date; usually this reflects the user's last logon date, but there is a class of profile updates that also affects this field. The accompanying time is found in the field LJTIME.

Another estimate of the last logon date is available in the field LAST_CONNECT_DATE, which is the maximum of the values in the CGLJDATE repeat group, and thus the date of the user's last RACINIT with any of his current connect groups. Note that this date might be set back to when the connect group last used for logon is deleted.

See also the CGLJDATE field.

LJTIME

This field is found in user profiles. It can only be used for output.It indicates the user's last logon time (the date of last logon is listed in LJDATE). See also the CGLJTIME field.

LNOTES

This field can only be used for SELECT/EXCLUDE processing. It selects LNOTES segments.

LOCALREGISTRY, LOCALREG

This field is found on the EIM segment of LDAPBIND and FACILITY class general resource profiles. On the IRR.PROXY.DEFAULTS profile in the FACILITY class it specifies the name of the local RACF registry in EIM domains. On IRR.ICTX.DEFAULTS[.*sysid*][profiles in the LDAPBIND class, this field specifies the registry used by the ICTX identity cache. On other profiles it is ignored. This field supports the `overtype` option which allows authorized users to change the field value from an ISPF panel.

LOGDAYS

For user profiles, this bit field lists the number of days a user cannot logon. For GENERAL profiles, this bit field listing the days a terminal cannot be used. See also the LOGTIME and LOGZONE fields. This field can only be used for output.

LOGTIME

For user profiles: a field listing the time of day a user can logon. For GENERAL profiles, you can use a field listing the time of day a terminal can be used. The output format of this field is *HHMM:HHMM* indicating the `starttime` and `endtime` when users have access, or *ANYTIME* if there are no time restrictions. See also the LOGDAYS and LOGZONE fields. This field can only be used for output.

LOGZONE

For GENERAL profiles, this field returns the time zone in which a terminal is located. The format of this field is 'E HH.MM' or 'W HH.MM'. This field can only be used for output.

LREFDAT

This date field is found in DATASET and GENERAL profiles and indicates the date the data set/resource was last referenced. This number is only updated for discrete profiles, and only then if statistics are on (due to SETROPTS STATISTICS).

MAGSTRIP

The operator identification associated with a user; only found in user profiles.

MAPPINGTIMEOUT,MAPTIMEO

This field is found in the ICTX segment of IRR.ICTX.DEFAULTS.** profiles in the LDAPBIND general resource class. It specifies the time (1-3600 seconds) the Identity Context Extension (ICTX) stores an identity mapping. This field supports `overtype` option.

MAPREQUIRED, MAPREQ

This field is found in the ICTX segment of IRR.ICTX.DEFAULTS.** profiles in the LDAPBIND general resource class. It specifies whether the Identity Context Extension (ICTX) requires identity mapping to a z/OS user ID. This field supports the `overtype` option which allows authorized users to change the field value from an ISPF panel.

MASK

This is an alias of FILTER field.

MATCH

This field can only be used for SELECT/EXCLUDE processing. It is used to search for all profiles that could match the resource name specified. The result includes both discrete and generic profiles; however, the indicated bit and the volume serials are ignored. This keyword is useful to determine what profiles would protect a resource if another profile was deleted. To search for an exact profile key, use the KEY field instead. To search using a generic pattern name, use the FILTER field instead.

For grouping profiles, the match is on the *member list* of the grouping profile. If a CLASS keyword is specified for a member class, the grouping class is automatically included. This allows selection of all profiles that could protect a CICS transaction; see also the examples at the end of this section.

Note that, if both the CLASS and MATCH keywords are specified, these two keywords should be the *first* keywords used in the SELECT/EXCLUDE statement or WHERE clause.

MAXTKTLF

This field can be found in the KERB segment for both the USER and the REALM General Resource class. It contains the maximum ticket life in seconds that is granted when generating a ticket for the target user or realm.

MAXFAIL

For GENERAL profiles: field in the SESSION segment listing the maximum number of invalid attempts before lockout.

MEMBERCLASS

For grouping profiles, this field contains the name of the corresponding member class. For a member profile, this field contains the name of the 'normal' profile class. For all other profile types, this field is undefined.

MEMBERKEY

This field can only be used for output. For grouping profiles, this repeated field contains the profile keys of all members. For all member profiles, this field contains the name of the 'normal' profile key. For all other profile types, this field is undefined.

MEMCNT

The number of members for a profile from a grouping class. The member class can be found using MEMBERCLASS. The MEMLST field lists the member profiles. Only found in GENERAL profiles.

MEMLIMIT

This field is found in user profiles and is part of the OMVS segment. It indicates the maximum number of bytes of non-shared memory that can be allocated by the user. It is a numeric value between 0 and 16 777 215, followed by the letter M, G, T, or P. The M, G, T or P stand for megabyte, gigabyte, terabyte and petabyte, respectively. This field supports the `overtype` option which permits authorized users to change the value from an ISPF panel.

MEMLST

The member list of a general resource from a grouping class. This is a repeated field; each entry can be up to 255 characters. The member class can be found using MEMBERCLASS. The MEMCNT field lists the number of members. Only found in GENERAL profiles.

MGMTCLAS

For GROUP and user profiles: DFP-management class in DFP segment.

MINTKTLF

This field can be found in the KERB segment for the REALM General Resource class. It contains the minimum ticket life in seconds that is granted when generating a ticket for the target realm.

MMAPAREAMAX

This field is found in user profiles and is part of the OMVS segment. It indicates the maximum amount of data space storage (in pages) that can be allocated for memory mappings of HFS files. It lies between 1 and 16,777,216.

MODEL

This field can only be used for SELECT/EXCLUDE processing. It corresponds to bit 1 in the DSTYPE field found in DATASET BASE segments. It indicates whether the profile is a model profile. It can be specified as an attribute, e.g., SELECT MODEL. Its opposite for the purpose of SELECT/EXCLUDE processing is NOMODEL. See also the DSTYPE field.

MODELNAM

The name of the data set model profile used to model new data set profiles created for the user or group. Up to 44 characters; only found in USER and group profiles.

MSGRECVR

This field is found in user profiles and is part of the NETVIEW segment. It contains a flag that indicates whether the operator can receive unsolicited Netview messages.

NAME

This is an alias of PGMRNAME (see “PGMRNAME” on page 1189).

NDS

This field can only be used for SELECT/EXCLUDE processing. It selects NDS segments.

NDSLINK_USERID

For a profile in the NDSLINK class, this field contains the userid this link is related to; for other classes it is always absent. When present, the content of this field is identical to that of the APPLDATA field.

NETVIEW

This field can only be used for SELECT/EXCLUDE processing. It selects NETVIEW segments.

NGMFADMN

This field is found in user profiles and is part of the NETVIEW segment. It contains a flag that indicates whether the operator can use the Netview Graphic Monitor Facility (NGMF).

NGMFVSPN

This field is found on the NETVIEW segment of the user profile. It contains the NetView Graphic Monitor Facility view span options.

NMAPCT

This field can be found in the BASE segment of the user profile. It is the count of digital certificate filters that map to this userid. The filter descriptions are listed in the NMAPNAME field, their labels in the NMAPLABL field.

NMAPLABL

This field is found in the BASE segment of the user profile. It is a repeat group field; its count is stored in the NMAPCT field. It shows the list of labels describing the digital certificate filters that map to this userid.

NMAPNAME

This field is found in the BASE segment of the user profile. It is a repeat group field; its count is stored in the NMAPCT field. It contains a list of the keys for the general resource profiles that describe the filters that map to this userid.

NO0LEVEL

Variable defined in C2RXDEF1 that is equivalent to `LEVEL`, except that it is missing when `LEVEL` is 0.

NOADSP

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the ADSP field. It selects user BASE segments for users that do no have the ADSP attribute. It can be specified as an attribute, e.g., SELECT NOADSP.

NOAUDITOR

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the AUDITOR field. It selects user BASE segments for users that do no have the system-auditor attribute. It can be specified as an attribute, e.g, SELECT NOAUDITOR.

NOAUTO

This is an alias of NOAUTOTAPE (see “NOAUTOTAPE”).

NOAUTOTAPE, NONAUTOTAPE, NOTAUTOTAPE, NOAUTO, NONAUTO, NOTAUTO

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the AUTOTAPE field. It selects TAPEVOL BASE segments for profiles that are not automatic TAPEVOL profiles. It can be specified as an attribute, e.g., SELECT NOAUTOTAPE. See also the RESFLG field.

NOCDTINFO

This field can only be used for SELECT/EXCLUDE processing. It selects non-CDTINFO segments.

NOCERTDATA

This field can only be used for SELECT/EXCLUDE processing. It selects non-CERTDATA segments.

NOCICS

This field can only be used for SELECT/EXCLUDE processing. It selects non-CICS segments.

NODCE

This field can only be used for SELECT/EXCLUDE processing. It selects non-DCE segments.

NODFP

This field can only be used for SELECT/EXCLUDE processing. It selects non-DFP segments.

NODLFDATA

This field can only be used for SELECT/EXCLUDE processing. It selects non-DLFDATA segments.

NOEIM

This field can only be used for SELECT/EXCLUDE processing. It selects non-EIM segments.

NOERASE

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the ERASE field. It selects DATASET BASE segments for profiles that do no have the erase-on-scratch flag set. That is, data sets that are not erased on scratch even if SETROPTS ERASE has been specified (without overriding suboperands). It can be specified as an attribute, e.g., SELECT NOERASE.

NOFAILLOAD

This field can only be used for SELECT/EXCLUDE processing. It selects non-FAILLOAD segments.

NOGROUPADSP

This is an alias of NOGRPADSP (see "NOGRPADSP" on page 1179).

NOGROUPAUDIT

This is an alias of NOGRPAUD (see "NOGRPAUD" on page 1179).

NOGROUPAUDITOR

This is an alias of NOGRPAUD (see "NOGRPAUD" on page 1179).

NOGROUPGRPACC

This is an alias of NOGRPGRPACC (see "NOGRPGRPACC" on page 1179).

NOGROUPOP

This is an alias of NOGRPOPER (see "NOGRPOPER" on page 1179).

NOGROUPOPER

This is an alias of NOGRPOPER (see "NOGRPOPER" on page 1179).

NOGROUPOPERATIONS

This is an alias of NOGRPOPER (see “NOGRPOPER”).

NOGROUPREVOKE

This is an alias of NOGRPREVOKE (see “NOGRPREVOKE” on page 1180).

NOGROUPSP

This is an alias of NOGRPSPEC (see “NOGRPSPEC” on page 1180).

NOGROUPSPEC

This is an alias of NOGRPSPEC (see “NOGRPSPEC” on page 1180).

NOGROUPSPECIAL

This is an alias of NOGRPSPEC (see “NOGRPSPEC” on page 1180).

NOGRPACC

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the GRPACC field. It selects USER BASE segments for users that do no have the system-GRPACC attribute. It can be specified as an attribute, e.g., SELECT NOGRPACC.

NOGRPADSP, NOGROUPADSP

This repeated field can only be used for SELECT/EXCLUDE processing,and acts as an opposite to the GRPADSP field. It selects USER BASE segments for users that have at least one connect group without the group-ADSP attribute. (To select USER BASE segments without any group-ADSP attribute, use NOT(GRPADSP) instead.) It can be specified as an attribute, e.g., SELECT NOGROUPADSP.

NOGRPAUD, NOGROUPAUDITOR, NOGROUPAUDIT, NOGRPAUDITOR, NOGRPAUDIT

This repeated field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the GRPAUD field. It selects USER BASE segments for users that have at least one connect group without the group-auditor attribute. (To select USER BASE segments without *any* group-auditor attribute, use NOT(GRPAUD) instead.) It can be specified as an attribute, e.g., SELECT NOGRPAUD.

NOGRPAUDIT

This is an alias of NOGRPAUD (see “NOGRPAUD”).

NOGRPAUDITPR

This is an alias of NOGRPAUD (see “NOGRPAUD”).

NOGRPGRPACC, NOGROUPGRPACC

This repeated field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the GRPGRPACC field. It selects USER BASE segments for users that have at least one connect group without the group-GRPACC attribute. (To select USER BASE segments without *any* group-GRPACC attribute, use NOT(GRPGRPACC) instead.) It can be specified as an attribute, e.g., SELECT NOGRPGRPACC.

NOGRPOP

This is an alias of NOGRPOPER (see “NOGRPOPER”).

NOGRPOPER, NOGROUPOPERATIONS, NOGROUPOPER, NOGROUPOP, NOGRPOPERATIONS, NOGRPOP

This repeated field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the GRPOPER field. It selects USER BASE segments for users that have at least one connect group without the group-operations attribute. (To select USER BASE segments without *any* group-operations attribute, use NOT(GRPOPER) instead.) It can be specified as an attribute, e.g., SELECT NOGRPOPER.

NOGRPOPERATIONS

This is an alias of NOGRPOPER (see "NOGRPOPER" on page 1179).

NOGRPREVOKE, NOGROUPREVOKE

This repeated field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the GRPREVOKE field. It selects USER BASE segments for users that have at least one unrevoked connect group. This field takes the revoke date, resume date, and the date of the RACF database unload (or the current date for a database) into account as well as the revoked flag. Use the CGFLAG4 field to select on just the revoke flag. (To select USER BASE segments without any revoked connects, use NOT(GRPREVOKE) instead.) It can be specified as an attribute, e.g., SELECT NOGRPREVOKE.

NOGRPSP

This is an alias of NOGRPSPEC (see "NOGRPSPEC").

NOGRPSPEC, NOGROUPSPEC, NOGROUPSP, NOGRPSPECIAL, NOGROUPSPECIAL, NOGRPSP

This repeated field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the GRPSPEC field. It selects USER BASE segments for users that have at least one connect group without the group-special attribute. (To select USER BASE segments without *any* group-special attribute, use NOT(GRPSPEC) instead.) It can be specified as an attribute, e.g., SELECT NOGRPSPEC.

NOGRPSPECIAL

This is an alias of NOGRPSPEC (see "NOGRPSPEC").

NOKERB

This field can only be used for SELECT/EXCLUDE processing. It selects non-KERB segments.

NOLANGUAGE

This field can only be used for SELECT/EXCLUDE processing. It selects non-LANGUAGE segments.

NOLNOTES

This field can only be used for SELECT/EXCLUDE processing. It selects non-LNOTES segments.

NOMODEL

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the MODEL field. It selects DATASET BASE segments for profiles that are not model profiles. It can be specified as an attribute, e.g., SELECT NOMODEL. See also the DSTYPE field.

NONAUTO

This is an alias of NOAUTOTAPE (see "NOAUTOTAPE" on page 1177).

NONAUTOTAPE

This is an alias of NOAUTOTAPE (see “NOAUTOTAPE” on page 1177).

NONDS

This field can only be used for SELECT/EXCLUDE processing. It selects non-NDS segments.

NONETVIEW

This field can only be used for SELECT/EXCLUDE processing. It selects non-NETVIEW segments.

NONREVOKED

This is an alias of NOREVOKE (see “NOREVOKE” on page 1182).

NONVSAM

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the VSAM field. It selects DATASET BASE segments for profiles that are not VSAM data set profiles. It can be specified as an attribute, e.g., SELECT NONVSAM. See also the DSTYPE field.

NOOIDCARD, NOOID

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the OIDCARD field. It selects USER BASE segments for users that do not require an OID card to logon. It can be specified as an attribute, e.g., SELECT NOOIDCARD.

NOOMVS

This field can only be used for SELECT/EXCLUDE processing. It selects non-OMVS segments.

NOOPER

This is an alias of NOOPERATIONS (see “NOOPERATIONS”).

NOOPERATIONS, NOOPER

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the OPERATIONS field. It selects USER BASE segments for users that do no have the system-operations attribute (and CONNECT profiles that do not have the group-operations attribute). It can be specified as an attribute, e.g., SELECT NOOPERATIONS.

NOOPERPARM

This field can only be used for SELECT/EXCLUDE processing. It selects non-OPERPARM segments.

NOOVM

This field can only be used for SELECT/EXCLUDE processing. It selects non-OVM segments.

NOPASSWORD

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the PASSWORD field. It selects USER BASE segments for users that do not require a password to logon. It can be specified as an attribute, e.g, SELECT NOPASSWORD.

NOPROTECTED

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the PROTECTED field. It selects USER BASE segments for users that

are not protected, for example, that can be revoked for too many invalid password attempts. It can be specified as an attribute, for example, SELECT NOPROTECTED.

NOPROXY

This field can only be used for SELECT/EXCLUDE processing. It selects non-PROXY segments.

NORESTRICTED

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the RESTRICTED field. It selects USER BASE segments for users that are not restricted, for example, that can be granted access through the Global Access Table, the UACC of a profile, or ID(*). It can be specified only as an attribute, for example,SELECT NORESTRICTED.

NOREVOKE, NONREVOKED, NOTREVOKED

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the REVOKE field. It selects USER BASE segments for users that are not revoked. This field takes the revoke date, resume date, and the date of the RACF database unload (or the current date for a database) into account as well as the revoked flag. Use FLAG4 (or CGFLAG4) to select based on the revoke flag only. It can be specified as an attribute, e.g., SELECT NOREVOKE.

NOSESSION

This field can only be used for SELECT/EXCLUDE processing. It selects non-SESSION segments.

NOSIGAUDIT

This field can only be used for SELECT/EXCLUDE processing. It selects segments which do non-SIGREQUIRED segments.

NOSIGREQUIRED

This field can only be used for SELECT/EXCLUDE processing. It selects non-SIGREQUIRED segments.

NOSIGVER

This field can only be used for SELECT/EXCLUDE processing. It selects non-SIGVER segments.

NOSINGLEDS

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the SINGLEDS field. It selects TAPEVOL BASE segments for profiles that do not have the single-data set flag set. It can be specified as an attribute, e.g., SELECT NOSINGLEDS. See also the RESFLG field.

NOSPEC

This is an alias of NOSPECIAL (see “NOSPECIAL”).

NOSPECIAL, NOSPEC

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the SPECIAL field. It selects USER BASE segments for users that do no have the system-special attribute. It can be specified as an attribute, e.g., SELECT NOSPECIAL.

NOSTDATA

This field can only be used for SELECT/EXCLUDE processing. It selects non-STDATA segments.

NOSVFMR

This field can only be used for SELECT/EXCLUDE processing. It selects non-SVFMR segments.

NOTAPE

This is an alias of NOTAPEDSN (see “NOTAPEDSN”).

NOTAPEDSN, NOTAPE

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the TAPEDSN field. It selects DATASET BASE segments for profiles that are not tape data set profiles. It can be specified as an attribute, e.g., SELECT NOTAPEDSN. See also the DSTYPE field.

NOTAUTO

This is an alias of NOAUTOTAPE (see “NOAUTOTAPE” on page 1177).

NOTAUTOTAPE

This is an alias of NOAUTOTAPE (see “NOAUTOTAPE” on page 1177).

NOTELINK_USERID

NOTERM

This is an alias of NOTERMUACC (see “NOTERMUACC”).

NOTERMUACC, NOTERM

This field can only be used for SELECT/EXCLUDE processing. It is found in GROUP BASE segments. It indicates the NOTRMUAC attribute, i.e, terminal access is not granted through the UACC of terminal profiles, but only through access list entries. It can be specified as an attribute, e.g., SELECT NOTERMUACC. Its opposite is TERMUACC.

NOTIFY

This field is found in DATASET and GENERAL profiles and indicates the user to notify when access violations occur for a data set or resource protected by the profile.

NOTME

This field can only be used for SELECT/EXCLUDE processing. It selects non-TME segments.

NOTREVOKED

This is an alias of NOREVOKE (see “NOREVOKE” on page 1182).

NOTRMUAC

For group profiles: terminal UACC. See also the CGNOTUAC field and NOTERMUACC fields.

NOTSO

This field can only be used for SELECT or EXCLUDE processing. It selects non-TSO segments.

NOTVTOC

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the TVTOC field. It selects TAPEVOL BASE segments for profiles that do not have a TVTOC. It can be specified as an attribute, e.g., SELECT NOTVTOC. See also the RESFLG field.

NOUAUDIT

This field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the UAUDIT field. It selects USER BASE segments for users that are not being audited. It can be specified as an attribute, e.g, SELECT NOUAUDIT.

NOUNIVERSAL

This field can only be used for SELECT/EXPLODE processing and acts as an opposite to the UNIVERSAL field. It selects GROUP BASE segments for groups that are not universal, for example, that are limited to 5957 connected users. It can be specified as an attribute, for example, SELECT NOUNIVERSAL.

NOWARN

This is an alias of NOWARNING (see "NOWARNING").

NOWARNING, NOWARN

Indicates if the data set or resource has the NOWARNING attribute, which indicates that access is denied if other profile settings indicate that access is not permitted. If this attribute is set, it selects BASE segments for data set and general resource profiles that are not in WARNING mode. This field is found in the BASE segment of DATASET and general resource profiles. The value can be specified as an attribute, SELECT NOWARNING for example.

NOWORKATTR

This field can only be used for SELECT/EXCLUDE processing. It selects non-WORKATTR segments.

NUMCTGY

This field is found in USER, DATASET, and GENERAL profiles. It lists the number of security category entries. The security categories are listed in the CATEGORY field.

OID

This is an alias of OIDCARD (see "OIDCARD").

OIDCARD, OID

This field can only be used for SELECT/EXCLUDE processing. It corresponds to the FLAG8 field found in USER BASE segments. It indicates whether an OID card is required to logon. It can be specified as an attribute, e.g., SELECT OIDCARD. Its opposite is NOOIDCARD.

OLDPHR

Repeated field listing an encrypted previous password phrase. Only found in the BASE segment of user profiles. The previous password phrase generation number is listed in the OLDPHRNM field; the count of previous password phrase generations is listed in the PHRCNT field.

OLDPHRNM

Repeated field listing a previous password phrase generation number. Only found in the BASE segment of user profiles. The previous password phrase is listed in the OLDPHR field; the count of previous password phrase generations is listed in the PHRCNT field.

OLDPWD

Repeated field listing an encrypted previous password. Only found in the BASE segment of user profiles. The previous password generation number is listed in the OLDPWDNM field; the count of previous password generations is listed in the PWDCNT field.

OLDPWDNM

Repeated field listing a previous password generation number. Only found in the BASE segment of user profiles. The previous password is listed in the OLDPWD field; the count of previous password generations is listed in the PWDCNT field.

OMVS

This field can only be used for SELECT/EXCLUDE processing. It selects OMVS segments.

OPCLASS

This field is found in user profiles in the CICS and NETVIEW segments. It is a repeated field; the number of values is listed in the OPCLASSN field in the same segment.

In the CICS segment, it is a repeated field listing the user's operator classes. Each operator class value is a number in the range 1 to 24.

In the NETVIEW segment, it is a repeated field listing the Netview scope classes over which the operator has authority. Each scope class value is a number in the range 1 to 2040.

OPCLASSN

This field is found in user profiles in the CICS and NETVIEW segments. It indicates the number of CICS operator class values (CICS segment) or NETVIEW scope classes (NETVIEW segment), which are listed in the OPCLASS field in the same segment.

OPER, OPERATIONS

This field is an alias for the FLAG3 field found in USER BASE segments. It indicates whether the user has the system-operations attribute. It can be specified as an attribute, e.g., SELECT OPERATIONS. Its opposite for the purpose of SELECT/EXCLUDE processing is NOOPERATIONS.

On standard userid overviews, this field is usually shown as the second position in a group column headed SOA (SPECIAL, OPERATIONS, and AUDITOR).

OPERATIONS

This is an alias of OPER (see “OPER”).

OPERALTG

This field is found in user profiles and is part of the OPERPARM segment. It contains a value for the ALTGRP keyword, which indicates the alternative console group for recovery.

OPERAUTH

This field is found in user profiles and is part of the OPERPARM segment. It can only be used for output. It contains a value for the AUTH keyword, which indicates the operator's command authority.

OPERAUTO

This field is found in user profiles and is part of the OPERPARM segment. It contains a value for the AUTO flag, which indicates whether the console is to receive messages specified for automation through MPF.

OPERCMDS

This field is found in user profiles and is part of the OPERPARM segment. It contains the CMDSYS keyword, which indicates the name of the system that the operator is connected to for command processing.

OPERDOM

This field is found in user profiles and is part of the OPERPARM segment. It can only be used for output. It contains a value for the DOM keyword, which indicates whether the operator receives delete operator message requests.

OPERHC

This field is found in user profiles and is part of the OPERPARM segment. It contains a value for the HC keyword, which indicates whether the operator receives messages that are directed to hardcopy.

OPERINT

This field is found in user profiles and is part of the OPERPARM segment. It contains a value for the INTIDS keyword, which indicates whether the operator receives messages directed to console ID 0 (the internal console). Such messages are usually responses to internally issued commands.

OPERKEY

This field is found in user profiles and is part of the OPERPARM segment. It contains the KEY keyword, which indicates the retrieval key used for a DISPLAY CONSOLES command.

OPERLEVL

This field is found in user profiles and is part of the OPERPARM segment. It can only be used for output. It contains a value for the LEVEL keyword, which indicates the message level that the operator receives.

OPERLOGC

This field is found in user profiles and is part of the OPERPARM segment. It contains a value for the LOGCMDRESP flag, which indicates whether command responses are to be recorded on the hardcopy log.

OPERMCNT

This field is found in user profiles and is part of the OPERPARM segment. It lists the count of MSCOPE systems, which are listed in the OPERMSCP field.

OPERMFRM

This field is found in user profiles and is part of the OPERPARM segment. It can only be used for output. It contains a value for the MFORM keyword, which indicates the format in which messages are displayed.

OPERMGID

This field is found in user profiles and is part of the OPERPARM segment. It contains a value for the MIGID flag, which indicates whether the operator is to receive a migration console id.

OPERMON

This field is found in user profiles and is part of the OPERPARM segment. It can only be used for output. It contains the MONITOR keyword, which indicates the events that are monitored.

OPERMSCP

This field is found in user profiles and is part of the OPERPARM segment. It is a repeated field listing the MSCOPE systems, from which unsolicited messages are received. The number is listed in the OPERMCNT field.

OPERPARM

This field can only be used for SELECT/EXCLUDE processing. It selects OPERPARM segments.

OPERROUT

This field is found in user profiles and is part of the OPERPARM segment. It can only be used for output. It contains a value for the ROUTCODE keyword, which indicates the routing codes that are received.

OPERSTOR

This field is found in user profiles and is part of the OPERPARM segment. It contains a value for the STORAGE keyword, which indicates the maximum message queue storage in Mb.

OPERUD

This field is found in user profiles and is part of the OPERPARM segment. It can only be used for output. It contains a value for the UD keyword, which indicates whether *undeliverable* messages are received.

OPERUNKN

This field is found in user profiles and is part of the OPERPARM segment. It contains a value for the UNKNIDS keyword, which indicates whether the operator receives messages directed to unknown console IDs. Unknown consoles are typically one-byte console IDs that the system cannot unambiguously resolve.

OPIDENT

This field is found in user profiles and is part of the CICS segment. It indicates the user's operator identification code. The length of this field is 3.

OPPRTY

This field is found in user profiles and is part of the CICS segment. It indicates the user's operator priority value, which is a number in the range 0 to 255.

OPTIONS

This field is found on the EIM segment of LDAPBIND and FACILITY class general resource profiles. It specifies options that control the EIM configuration. This field supports the `overtype` option which permits authorized users to change the value from an ISPF panel.

OVM

This field can only be used for SELECT/EXCLUDE processing. It selects OVM segments.

OWNER, AUTHOR

The RACF user or group id of the profile's owner. Found in all profile types.

PACSCNT

Access count of a conditional access list entry. This number is only updated for discrete profiles, and only then if statistics are on (due to SETROPTS STATISTICS). This is a repeated field that can be combined with the PROGACS, USER2ACS, PROGRAM, and ACL2VAR fields. Found in DATASET profiles. The number of conditional access list entries is listed in the ACL2CNT field.

PADS

This field can only be used for SELECT/EXCLUDE processing and selects profiles in the PROGRAM class as well as data set profiles with a conditional access list. It can be specified as an attribute, for example, SELECT PADS.

PARENT

This field is found in the ROLE class as part of the TME segment. It is the parent role of this role.

PARMN

This field is found on the SVMR segment of the SYSMVIEW general resource profile. It contains the SystemView parameter name.

PASSASIS

This flag field is found in the BASE segment of user profiles and indicates that password checks for the user are case-sensitive.

On standard userid overviews, this field is usually shown as the last position in a group column headed EPEM (the first E means the user has a password envelope; P means the user has a password phrase; the next E means the user has a password phrase envelope; M means that password checks for the user are case-sensitive).

PASSDATE

A user's last password change date. Only found in the BASE segment of user profiles.

PASSINT

This field is only found inuser profiles and indicates the password interval in effect for the user. Valid interval values are 1 to 254; for any user, the lowest value of PASSINT and the system's password interval settings are used. The special value 255 (displayed as blank) indicates the user has a password that never expires.

PASSINT_EFFECTIVE

This field contains the effective password interval for a userid; it is in principle derived from the PASSINT field in the user profile and the SETROPTS PASSWORD(INTERVAL()) setting. Unless the user setting is NOINTERVAL (which is honored), RACF effectively uses the minimum of the two intervals. However, if this minimum is lower than the SETROPTS PASSWORD(MINCHANGE()) setting, the MINCHANGE setting is used instead. See also PASSWORD_EXPIRE_DATE and PASSWORD_EXPIRED.

Users that are assigned the PROTECT attribute cannot log on using a password; this field returns a missing value for these users.

PASSWORD

This field corresponds to the complement of the bit 0 in the FLAG7 field found in USER BASE segments. It indicates whether a password is required to logon. For SELECT/EXCLUDE processing, it can be specified as an attribute, e.g., SELECT PASSWORD. When used for output, it displays the encrypted password associated with the user. In an unloaded database, this field always contains asterisks. The user is not able to actually use the password to logon if he is also PROTECTED. The field's opposite for the purpose of SELECT/EXCLUDE processing is NOPASSWORD.

PASSWORD_EXPIRE_DATE

Contains the expiration date for the user password. Normally, this value is the sum of the last password change date and the effective password interval. PASSWORD_EXPIRE_DATE=NEVER selects users with NOINTERVAL. If you use an inequality operator in the selection criteria, include a separate EXCLUDE statement for the NEVER value.

User passwords that have explicitly been set to *expired* have an expiration date in the past. The last use date is returned if it is nonblank, as an estimate of when the password was set to *expired*. For a userid that has never been used, the creation date is returned in the PASSWORD_EXPIRE_DATE field. These values are returned so that these entries can be identified in queries to locate recently expired userids. See also PASSINT_EFFECTIVE and PASSWORD_EXPIRED.

Users assigned the PROTECT attribute cannot log on using a password; this field returns NEVER for these users.

PASSWORD_EXPIRED

This flag field indicates whether a userid has an expired password. This flag pertains to the unload date rather than today. To search for the password status as of today using an unload data set, specify the following query: PASSWORD_EXPIRE_DATE <>NEVER AND PASSWORD_EXPIRE_DATE<=TODAY. See also PASSWORD_EXPIRE_DATE and PASSINT_EFFECTIVE.

On standard userid overviews, this field is usually shown as the last position in a group column headed LCX which shows flag fields to indicate the following conditions.

L means the user has at least one RACLINK

C means the user has a certificate.

X means that the password for the user has expired.

PGMRNAME, NAME

User name (20 characters). This field is only available for profiles of class USER.

PHRASE

This field can only be found in the BASE segment of user profiles. It displays the encrypted password phrase associated with the user. In an unloaded database, this field always contains asterisks.

PHRASE_EXPIRED

This flag field indicates whether a userid has an expired password phrase. This flag pertains to the unload date rather than today; if you want to know about today's status, you can use a query like PHRASE_EXPIRE_DATE <>NEVER AND PHRASE_EXPIRE_DATE<=TODAY. See also PHRASE_EXPIRE_DATE, PASSINT_EFFECTIVE, PASSWORD_EXPIRE_DATE, and PASSWORD_EXPIRED.

PHRASE_EXPIRE_DATE

Contains the password phrase expiration date for the user. Normally, this value is the sum of the last password phrase change date and the effective password interval. PHRASE_EXPIRE_DATE=NEVER selects users that have no password interval specified (NOINTERVAL). If you use an inequality operator in the selection criteria, include a separate EXCLUDE statement for the NEVER value.

User password phrases that have explicitly been set to *expired* have an expiration date in the past. For these password phrases, the *last use date* is returned if it is nonblank to provide an estimate when the password phrase was set to expired. For userids that have never been used, the creation date is returned in the PHRASE_EXPIRE_DATE field. These values are returned so that these entries can be identified in queries to locate recently expired userids. See also PASSINT_EFFECTIVE, PHRASE_EXPIRED, PASSWORD_EXPIRE_DATE, and PASSWORD_EXPIRED.

Users assigned the PROTECT attribute cannot log on using a phrase; this field returns NEVER for these users.

PHRCNT

This field contains the count of previous password phrase generations. Only found in the BASE segment of user profiles. The previous password phrase generations are listed in the OLDPHRNM and OLDPHR fields. This field is only used if the SETROPTS PASSWORD(HISTORY) option is or was active.

PHRDATE

user profile

This field is found in the BASE segment of user profiles and it contains the user's last password phrase change date. Only found in the BASE of user profiles.

PHRGEN

Current password phrase generation number, from the BASE segment of a user profile.

PPHENV

This field lists the content of the Password Phrase Envelope field of a user profile. It contains a decrypted form of the user password phrase.That is, a two-way encrypted form of the phrase in contrast to the PHRASE field, which uses a one-way encrypted value.

By default this field is shown 40 characters long, as a text string with values that cannot be printed replaced with a period. This field can only be shown from a RACF database, it is masked in data from an UNLOAD file.

PREVKEY

This field can be found in the KERB segment for both the USER and the REALM General Resource class. It contains the previous key for the user or realm in encrypted form. This field is removed from any UNLOAD made.

PREVKEYV

This field can be found in the KERB segment for both the USER and the REALM General Resource class. It contains the version number of the previous key for the user or realm.

PROCUSERMAX

This field is found in user profiles and is part of the OMVS segment. It indicates the maximum number of processes that this user is permitted to have active at

the same time, regardless of how the process became a z/OS UNIX System Services process. It lies between 3 and 32,767.

PROFILE

This is an alias of KEY (see "key" on page 1172).

PROFILE_USED

This field is a flag that indicates whether RACF uses the profile in authorization checking or not. If the flag is No, you can use the field AUDITCONCERN in zSecure Audit for RACF to display the reason why the profile is not used. The reason can for instance stem from the router table, the class descriptor table, SETROPTS class settings, or the range table (if SUPPRESS ICHRRNG was specified).

PROFLEN

This field is defined for all profiles and contains the logical length of the profile (segment) in the RACF database, in bytes. Up to 7 digits.

PROFTYPE

This field can only be used for output. For general resource profiles, this results in a blank field (for discretes) or the word GENERIC (for generics). For data set profiles, this results in one of the words GENERIC, NONVSAM, VSAM, TAPEDSN, or MODEL. For USER, GROUP, and CONNECT profiles, the field is '**n/a**'.

PROGACS

The access level of a conditional access list entry. This is a repeated field that can be combined with the PACSCNT, USER2ACS, PROGRAM, and ACL2VAR fields. Found in DATASET profiles. The number of conditional access list entries is listed in the ACL2CNT field. The easiest way to display normal and conditional access list entries is the ACL combination field. The PROGACS field can have the following values:

- ALTER
- CONTROL
- UPDATE
- READ
- EXECUTE
- NONE

PROGRAM

The PROGRAM field is found in the BASE segment of DATASET profiles and in the OMVS segment of user profiles; it has a different meaning in the two profile types.

In DATASET profiles, it indicates the program name of a conditional access list entry. This is a repeated field that can be combined with the PROGACS, USER2ACS, PACSCNT, and ACL2VAR fields. The number of conditional access list entries is listed in the ACL2CNT field. The easiest way to display normal and conditional access list entries is the ACL combination field.

In user profiles, it indicates the start-up program or shell used for z/OS UNIX. The start-up program is a case-sensitive character string of up to 1024 characters.

PROTECTED

This field is found in USER BASE segments. It indicates if the user is protected. A protected user does not have a password or an `oidcard` and can only be used to enter the system in a way that does not support passwords. For example, the ID can be used for a started task. The specified user ID cannot be revoked for invalid password attempts. The `PROTECTED` value can be specified as an attribute, SELECT PROTECTED for example. Its opposite for the purpose of SELECT/EXCLUDE processing is NOPROTECTED.

On standard `userid` overviews, this field is usually shown as the last position in a group column headed RIRP (REVOKED, REVOKE_INACTIVE, RESTRICTED, and PROTECTED).

Note: RACF databases on z/OS have slightly different bit settings from those on z/VM. This field is meant for use on z/OS. See `PROTECTED_ZVM`.

PROTECTED_ZVM

Variable defined in C2RXDEF1 that is the equivalent of PROTECTED for RACF for z/VM databases.

PROXY

This field can only be used for SELECT/EXCLUDE processing. It selects PROXY segments.

PWDCNT

Field listing the count of previous password generations. Only found in the BASE segment of user profiles. The previous password generations are listed in the OLDPWDNM and OLDPWD fields. This field is only used if the SETROPTS PASSWORD(HISTORY) option is or was active.

PWDENV

This field lists the content of the Password Envelope field of a user profile. It contains a decrypted form of the user password. That is, the password is two-way encrypted. This field value is in contrast to the PASSWORD field, which is provides the password in a one-way encrypted form.

PWDGEN

Current password generation number, from the BASE segment of a user profile.

PWHASHED

This field can only be used on a RACF database, and is blank for an unloaded database. It is YES if the password has been encrypted using the hashing algorithm, NO otherwise. Note: There is a very remote possibility that this field is set to YES for a DES-encrypted password. In that case, two different passwords exist that both lead to the same encrypted passwords, one with the DES algorithm and one with the hashing algorithm. If your installation has the password encryption exit ICHDEX01 or ICHDEX11 set to migration, both passwords can be used to logon.

QUAL

The QUAL field on a LIST family command contains the first qualifier for data set and general resource profiles, and contains the profile key for user and group profiles. For data set profiles, *id* matches the first qualifier (as changed by ICHCNX00 and ICHNCV00).

On a SELECT family command it matches any profile if the class is not DATASET, and restricts class DATASET profiles to those with a matching first

qualifier as modified by ICHCNX00 and ICHNCV00. A field-field comparison, however, is **not** restricted to the DATASET class.

QUAL1

The QUAL1 field contains the first qualifier for data set and general resource profiles, and contains the profile key for user and group profiles. For data set profiles, *id* matches the actual first qualifier (*not* as changed by ICHCNX00).

RACLDSP

This field is defined in the BASE segment of the RACGLIST general resource class. It is used for RACLIST processing.

RACLHDR

This field is defined in the BASE segment of the RACGLIST general resource class. It is used for RACLIST processing.

RACLINK

This repeated field lists information in the user profile set by RACLINK. It lists the following columns: `linked node`, `remote userid`, type of the link record (*Peer*, *Slave*, or *Master*, status ('*Err*, *Pend*, or blank), whether passwords are to be synchronized (*Sync* or blank), time stamps for creation and approval (both in GMT in the format `yyyy/mm/dd hh:mm`, and creating `userid`. The linked node, link record type, and password fields are modifiable. Authorized users can edit the values for these fields interactively from the `RACLINK` section on the User Profile detail display panel. See "User profile detail display" on page 92.

See also the TUDATA field.

RACMAP_CMD_FILTER

Repeat group pseudo field that is equivalent to `DMAPNAME`, except that quotes are doubled and `OPTION MY_CCSID=`*`ccsid`* has no influence on the output from this field: Conversion to EBCDIC always uses code page 1047. This field is intended to be used when generating RACMAP commands in CARLa. This field can only be used for output and selection with the EXISTS and MISSING keywords. (See "Selecting on field existence" on page 886.)

RACMAP_CMD_REGISTRY

Repeat group pseudo field that is equivalent to `RACMAP_REGISTRY`, except that quotes are doubled and `OPTION MY_CCSID=`*`ccsid`* has no influence on the output from this field. Conversion to EBCDIC always uses code page 1047. This field is intended to be used when generating RACMAP commands in CARLa. This field can only be used for output and for selection with the EXISTS and MISSING keywords. (See "Selecting on field existence" on page 886.)

RACMAP_REGISTRY

This repeat group pseudo field is found in the `BASE` segment of user profiles. It contains the registries for the identity mappings to this userid. The repeat count is contained in the `DMAPCT` field. This field can only be used for output and for selection with `EXISTS` and `MISSING`. For additional information, see the following field descriptions: `DMAPCT`, `DIDRNAME`, `DMAPLABL`, and `RACMAP_CMD_REGISTRY`.

RBA

This field is defined for all profile types and contains the Relative Byte Address of the selected profile (segment) within the containing data set of the originating database. Together with the DB field, this uniquely identifies a profile

(segment). Its main use is to keep operating in situations where BAM conflicts are reported by IRRUT200, for instance by excluding profiles that are in use, but not present in the index.

RCVT_RACFLEVEL

This field indicates the software level of RACF in a four-character format, for example: '7705'. The RACFLEVEL format can be used to format the software level of RACF as an SMP /E FMID, for example: '7.7.5'.

This field can be used in a DEFINE statement to generate certain keywords if the RACF level satisfies a condition, for example:

```
DEFINE generate_shared(str$blank(' shared') 0) TRUE,WHERE RCVT_RACFLEVEL>='7705'
```

RECNO

This pseudofield is defined for all profiles in an UNLOAD. It contains the record number of the profile. For all profiles in a DATABASE, this pseudo field contains zero.

RECREATE_KEY

This field is used by an internal CARLa script (CKRXRDS) to reformat nine-character data set profile names terminated by an asterisk (*) into valid RACF profile names. Generic data set profile names such as AAA.ABCDEFGH*.** are rejected by the ADDSD command. A generic profile such as AAA.ABCDEFGH*, created without the EGN option, is converted to AAA.ABCDEFGH*.** when the enhanced generic name (EGN) option is activated. The CARLa script (CKRXRDS) uses the RECREATE_KEY field to strip out the extra asterisk (*) and create a valid name, for example AAA.ABCDEFGH.**

RESFLG

This flag field is found in TAPEVOL BASE segments. It can only be used for output processing. The output is a three-character field in the form SAT. The first character describes the SINGLEDSN flag, and is blank if this flag is not set, and 'S' if this flag is set. The second character describes the AUTOTAPE flag, and is blank if this flag is not set, and 'A' if this flag is set. The last character describes the TVTOC flag, and is blank if this flag is not set, and 'T' if this flag is set. For SELECT/EXCLUDE processing, use the SINGLEDS, AUTOTAPE, and TVTOC fields.

RESN

This field is found in the ROLE class and is part of the TME segment. It is the count of resource access specifications of the role. These resource access specifications are listed in RESOURCE.

RESOURCE

This field is found in the ROLE class as part of the TME segment. It is a repeat group field; the repeat count is stored in the RESN field. It contains the list of resource access specifications of the role.

RESOWNER

This field is only found in the DFP segment of DATASET profiles. It indicates the DFP-RESOURCE owner, for example, the group or user from which the DFP segment is used for the creation of a new data set.

RESTRICTED

This field is an alias for the FLAG9 field found in USER BASE segments. It indicates whether the user has the RESTRICTED attribute, for example, that the user cannot be granted access through the global access table, the UACC of a profile, or ID(*). It can be specified as an attribute, e.g., SELECT RESTRICTED. Its opposite for the purpose of SELECT/EXCLUDE processing is NORESTRICTED.

On standard userid overviews, this field is usually shown as the third position in a group column headed RIRP (REVOKED, REVOKE_INACTIVE, RESTRICTED, and PROTECTED).

RESUMEDT

Resume date of a user from the user profile or group-connect. Found in user profiles. See also the CGRESMDT field.

RETAIN

For GENERAL profiles, flag byte field in the DLFDATA segment that contains the retain setting which indicates whether the DLF object can be retained after use.

RETPD

This field is found in GENERAL profiles and can only be used for output. The retention period, for example, the number of days protection is provided for the tape data set. A numerical value in the range 0 to 65533, with the value 99999 indicating no expiration.

REVOKE, REVOKED

This field is found in USER BASE segments. It indicates whether the user is revoked. The alias REVOKED can only be used for SELECT/EXCLUDE processing. It can be specified as an attribute, e.g., SELECT REVOKE. This field takes the revoke date, resume date, and the date of the RACF database unload (or the current date for a database) into account as well as the revoked flag. Use the FLAG4 (or CGFLAG4) field to display just the revoke flag. The field's opposite for the purpose of SELECT/EXCLUDE processing is NOREVOKE.

On standard userid overviews, this field is usually shown as the first position in a group column headed RIRP (REVOKED, REVOKE_INACTIVE, RESTRICTED, and PROTECTED).

REVOKED

This is an alias of REVOKE (see “REVOKE”).

REVOKE_INACTIVE

This pseudo-field flag indicates whether the user would be revoked due to inactivity the moment he tried to logon or start a job. It takes into account the global SETROPTS INACTIVE setting and the user's last use date.

On standard userid overviews, this field is usually shown as the second position in a group column headed RIRP (REVOKED, REVOKE_INACTIVE, RESTRICTED, and PROTECTED).

REVOKECT

Count of unsuccessful password attempts. This field is only found in user profiles.

Note: RACF only updates this value if user-revokes are in effect because of a SETROPTS PASSWORD(REVOKE) command.

REVOKEDT

Revoke-by date of a user. Found in USER and CONNECT profiles. See also the CGREVKDT field.

RINGCT

This field can be found in the CERTDATA segment of the DIGTCERT general resource class. It is a count of the keyrings to which the digital certificate is connected.

RINGNAME

This field can be found in the CERTDATA segment of the DIGTCERT general resource class. It is a repeat group field; the repeat count is stored in the RINGCT field. It contains a list of full names (`userid` and `keyringname`) of the keyrings to which this digital certificate is connected.

RINGSEQN

This field can be found in the CERTDATA segment of the DIGTRING general resource class. It contains an automatically generated sequence number, defining the ring.

ROLEN

This field is found in GENERAL, GROUP and DATASET profiles and is part of the TME segment. It is the count of roles associated with the profile. These roles are listed in ROLES.

ROLES

This field is found in GENERAL, GROUP and DATASET profiles as part of the TME segment. It is a repeat group field; the repeat count is stored in the ROLEN field. It contains the list of roles associated with the profile.

RSLKEY

This repeated field is found in user profiles and is part of the CICS segment. It contains the Resource Security Level Keys that are assigned to the user. The number of RSLKEYs is stored in the RSLKEYN field. For administration purposes it is recommended to use the CICS_RSLKEY pseudo field instead, which supports command generation and the `overtype` option for changing field values from an ISPF panel.

RSLKEYN

This field is found in user profiles and is part of the CICS segment. It contains the number of Resource Security Level Keys that is assigned to the user. The keys themselves are listed in the RSLKEY field.

SALT

This field can be found in the KERB segment for the REALM General Resource class. It contains the seed used by this realm in its random generation processing. This field is removed from any UNLOAD made.

SCRIPTN

This field is found on the SVMR segment of the SYSMVIEW general resource profile. It contains the SystemView script name.

SEARCHKEY

This field contains the profile key in RACF sort order, for example, generic characters sort after alphanumerical characters. The main use of this field is to

change the sort order. Because it contains unprintable data, the NONDISPLAY output modifier is recommended. Sort RACF profiles in search order by making SEARCHKEY(NONDISPLAY) the first field of a SORTLIST/DISPLAY.

SECLABEL

User/data set/resource security label. This field is found in USER, DATASET, GENERAL profiles.

SECLEVEL

User/data set/resource security level. This field is found in USER, DATASET, and GENERAL profiles. For SELECT/EXCLUDE processing, a hexadecimal (internal) value must be specified.

SECUREEXPORT

Flag field that can only be found in the ICSF segment which specifies attributes for the keys controlled by general resources profiles in classes CSFKEYS, GCSFKEYS, XCSFKEY,and GXCSFKEY. It indicates whether the asymmetric key controlled by these profiles can be used to export or import symmetric keys. You can use overriding format $NO for command generation in combination with the ASYMUSAGE keyword. See also “CSFAUSE” on page 1154.

SEGCNT

This field is only found in very old (pre-RACF 1.9.2), so-called *non*-RDS, RACF databases, for all profile types. It indicates the number of segments included in the profile. The basic profile contents (which is called the BASE profile) is not counted as a segment. The segment names are listed in the SEGNAME field.

SEGMENT

This indicates the 8 character segment type of the selected profile segment, including BASE. Use the SEGNAME field to display all segment names from the profile.

For SELECT/EXCLUDE processing, this parameter selects the indicated segment types.

SEGNAME

This repeated field is only found in very old (pre-RACF 1.9.2), so-called *non*-RDS, RACF databases, for all profile types. It lists the names of the segments included in the profile. The basic profile contents (which is called the BASE profile) are not counted as a segment. The number of segment names that are listed is in the SEGCNT field.

SENTCNT

For GENERAL profiles: field in the SESSION segment containing the number of session entities. The entities are listed in the SENTITY and SENTFLCT fields.

SENTFLCT

For GENERAL profiles: field in the SESSION segment containing the number of failed attempts for the session entity. This is a repeated field that can be combined with the SENTITY field. The number of entities listed is in the SENTCNT field.

SENTITY

For GENERAL profiles: field in the SESSION segment containing the session entity name. This is a repeated field that can be combined with the SENTFLCT field. The number of entities listed is in the SENTCNT field.

SESSION

This field can only be used for SELECT/EXCLUDE processing. It selects SESSION segments.

SESSKEY

For GENERAL profiles: field in the SESSION segment containing the session key. This is an 8 byte DES key stored in clear text. The low-order bits of each byte are parity bits that do not change the actual key.

SHMEMMAX

This field is found in user profiles and is part of the OMVS segment. It indicates the maximum number of bytes of shared memory that can be allocated by the user. It is a numeric value between 0 and 16 777 215, followed by the letter M, G, T, or P. The M, G, T or P stand for megabyte, gigabyte, terabyte and petabyte, respectively. This field supports the `overtype` option.

SIGAUDIT

SIGAUDIT is found in GENERAL resource profiles and is part of the SIGVER segment. The value in this field indicates under what conditions RACF records an SMF type 80 record with qualifier code 86. The possible conditions are: `ALL`, `SUCCESS`, `ANYBAD`, `BADSIGONLY`, `NEVER`.

Table 404. Signature Verification validation - Conditions for logging

Value	Description
ALL	Specifies logging all signature verifications, whether successful or not.
SUCCESS	Specifies logging only signature verification successes.
ANYBAD	Specifies logging only signature verification failures, regardless of the cause.
BADSIGONLY	Specifies logging only signature verification failures caused by an incorrect digital signature.
NONE	Specifies that signature verification events are *never* to be logged.

SIGREQUIRED, SIGREQD

SIGREQUIRED is found in `GENERAL` resource profiles and is part of the `SIGVER` segment. This is a flag field that indicates whether a signature is required in order for a program to be loaded. This field can have the following values:

- `YES` specifies that a program protected by the profile must be digitally signed.
- `NO` specifies that a program protected by the profile need not be digitally signed.

Selection can be based on the value of the field or the presence of the field.

SIGVER

This is the name of an optional PROGRAM class GENERAL resource profile segment. This field can only be used for SELECT/EXCLUDE processing. It selects SIGVER segments.

SINGLEDS

This field can only be used for SELECT/EXCLUDE processing. It corresponds to bit 0 in the RESFLG field found in TAPEVOL BASE segments. It indicates whether the single-data set flag is set. It can be specified as an attribute, e.g.,

SELECT SINGLEDS. Its opposite for the purpose of SELECT/EXCLUDE processing is NOSINGLEDS. See also the RESFLG field.

SLSFAIL

For general resource profiles, this field provides the current number of invalid attempts field. This field is in in the SESSION segment listing.

SLSFLAGS

For GENERAL profiles: flags in the SESSION segment. Currently, only one flag bit (bit 0) has been defined. If set, the profile is locked out.

SNAME

This field is found in user profiles and is part of the LNOTES segment. It indicates the Lotus Notes short name for this user. Care must be taken to ensure that this field has a unique value for each user.

SPEC

This is an alias of SPECIAL (see "SPECIAL").

SPECIAL, SPEC

This field is an alias for the FLAG2 field found in USER BASE segments. It indicates whether the user has the system-special attribute. It can be specified as an attribute, e.g., SELECT SPECIAL. Its opposite for the purpose of SELECT/EXCLUDE processing is NOSPECIAL.

On standard userid overviews, this field is usually shown as the first position in a group column headed SOA (SPECIAL, OPERATIONS, and AUDITOR).

SSKEY

This field is found in PTKTDATA profiles and is part of the SSIGNON segment. It contains an encrypted (or masked) 8 byte secure-signon key. The default display format is hex. An `UNLOAD` operation replaces this field by asterisks (X'5C').

STAMP

If the RACF database is an `UNLOAD` file, this field displays the local date and time of the `UNLOAD` operation. If the database is live, it displays current date and time. For a copy of a database, it is displayed as '00:00:00.000000'.

STDATA

This field can only be used for SELECT/EXCLUDE processing. It selects STDATA segments.

STGROUP

This field is found in STARTED profiles and is part of the STDATA segment. It contains the group id to be used for a started procedure matching the STARTED profile. The special value =MEMBER indicates that the started procedure name must be used as the groupid.

STORCLAS

For GROUP, user profiles: DFP-storage class in DFP segment.

STUSER

This field is found in STARTED profiles and is part of the STDATA segment. It contains the userid to be used for a started procedure matching the STARTED profile. The special value =MEMBER indicates that the started procedure name must be used as the userid.

SUBGRPCT

This field lists the number of subgroups. This field is only found in group profiles. The SUBGRPNM field lists the subgroups.

SUBGRPNM

This is a repeated field listing the subgroups of a group. This field is only found in group profiles. The SUBGRPCT field contains the number of subgroups.

SUPGROUP

The superior group of a group. This field is only found in group profiles.

SVFMR

This field can only be used for SELECT/EXCLUDE processing. It selects SVFMR segments.

SYMEXPORTABLE

See “CSFAUSE” on page 1154.

SYMEXPORTCERTS

See “CSFSCLBS” on page 1156.

SYMEXPORTKEYS

See the “CSFSKLBS” on page 1156.

SYMCPACFWRAP

See the CSFSCPW field.

TACCNT

This field is found in user profiles and is part of the TSO segment. It indicates the user's default account number.

TAPE

This is an alias of TAPEDSN. See “TAPEDSN.”

TAPEDSN, TAPE

This field can only be used for SELECT/EXCLUDE processing. It corresponds to bit 2 in the DSTYPE field found in DATASET BASE segments. It indicates whether the profile is a tape data set profile. It can be specified as an attribute, e.g., SELECT TAPEDSN. Its opposite for the purpose of SELECT/EXCLUDE processing is NOTAPEDSN. For output, use the DSTYPE field.

TCOMMAND

This field is found in user profiles and is part of the TSO segment. It indicates the user's default command at logon.

It can be set using the CKGRACF FIELD command, or by the RACF ALTUSER command.

TCONS

This field is found in user profiles and is part of the TSO segment. It indicates the consoles support.

TDEST

This field is found in user profiles and is part of the TSO segment. It indicates the user's default output destination identifier.

TERMUACC

This flag field can only be used for SELECT/EXCLUDE processing and acts as an opposite to the NOTERMUACC field. It selects GROUP BASE segments without the NOTRMUAC attribute, for example, terminal access might be granted through the UACC of TERMINAL profiles. It can be specified as an attribute, for example, SELECT TERMUACC.

THCLASS

This field is found in user profiles and is part of the TSO segment. It indicates the user's default hold class.

THREADSMAX

This field is found in user profiles and is part of the OMVS segment. It indicates the maximum number of pthread_created threads, including those running, queued, and exited but not detached, that this user can have currently active. It lies between 0 and 100,000.

TIMEOUT

This field is found in user profiles and is part of the CICS segment. It indicates the user's terminal time-out value, which is the number of minutes a user must be inactive before CICS times out the terminal. This is a hh:mm value with mm in the range 0 to 59. Note that CICS rounds values up to the nearest multiple of 5. The length of this field is 5.

TJCLASS

This field is found in user profiles and is part of the TSO segment. It indicates the user's default job class.

TLPROC

This field is found in user profiles and is part of the TSO segment. It indicates the user's logon procedure.

TLSIZE

This field is found in user profiles and is part of the TSO segment. It indicates the user's logon region size, in units of 1024 bytes.

TMCLASS

This field is found in user profiles and is part of the TSO segment. It indicates the user's default message class for submitted jobs.

TME

This field can only be used for SELECT/EXCLUDE processing. It selects TME segments.

TMSIZE

This field is found in user profiles and is part of the TSO segment. It indicates the user's maximum region size, in units of 1024 bytes.

TOPTION

This field is found in user profiles and is part of the TSO segment. This field can only be used for output and displays TSO logon options in a 4 character field. It can be a combination of the letters MNRO for MAIL, NOTICE, RECOVER and OIDCARD, respectively.

TPERFORM

This field is found on the TSO segment of the user profile. It contains the performance group to which this user belongs.

TRBA

This field is found in user profiles and is part of the TSO segment. It indicates the RBA of the user's broadcast area (the offset within the SYS1.BRODCAST data set).

TREELINE

Internal sort key for a group-tree display. This field, which is only defined for group profiles, and might only be used with the SORTLIST, DISPLAY and (D)SUMMARY commands, indicates the position of the group within the group tree. This field does not result in 'pretty' output. Sort the group entries in a tree by making TREELINE(NONDISPL) the first field of a SORTLIST/DISPLAY.

TSCLASS

This field is found in user profiles and is part of the TSO segment. It indicates the user's default `sysout` class for printed output.

TSLKEY

This repeated field is found in user profiles and is part of the CICS segment. It contains the Transaction Security Level Keys that are assigned to the user. The number of TSLKEYs is stored in the TSLKEYN field. For administration purposes it is recommended to use the CICS_TSLKEY pseudofield instead, which supports command generation and the `overtype` option which permits authorized users to change the field value from an ISPF panel.

TSLKEYN

This field is found in user profiles and is part of the CICS segment. It contains the number of Transaction Security Level Keys that is assigned to the user. The keys themselves are listed in the TSLKEY field.

TSO

This field can only be used for SELECT/EXCLUDE processing. It selects TSO segments.

TSOSLABL

This field is found in user profiles and is part of the TSO segment. It indicates the default logon `seclabel` for the user.

TUCNT

This field is found in user profiles. It indicates the number of target userid entries. The entries are listed in the TUKEY and TUDATA fields.

TUDATA

This field is found in user profiles in the BASE and TSO segments.

In the TSO segment, it contains the TSO user data (carried over from SYS1.UADS). This field consists of 4 characters in the range 0-9 and A-F.

In the BASE segment, it is a repeated field that is described with the TUCNT field. Each entry contains the RACLINK status fields used for automatic command redirection. The corresponding target user is described in the TUKEY field. When output, this field contains the following subfields:

Table 405. TUDATA output - fields and descriptions

Field	Values	Meaning
Type	Master Peer Slave	Link type Authorized users can change the value in this field interactively in the RACLINK section of the User Profile detail display panel. See"User profile detail display" on page 92.
Stat	Err Pend (blank)	Link status (error, pending approval, or approved)
Pwd	Sync (blank)	Password synchronization flag. Authorized users can change the value in this field interactively from the ISPF User Profile detail display. See "User profile detail display" on page 92.
Defined	Time stamp	Time link was defined
Approved	Time stamp	Time link was approved
Creator	Userid	User that created link

See also the RACLINK field.

TUKEY

This field is found in user profile in the BASE segment. It is a repeated field that is described with the TUCNT field. Each entry contains a target userid for automatic command redirection. The corresponding RACLINK flags are described in the TUDATA field.

TUNIT

This field is found in user profiles and is part of the TSO segment. It indicates the user's default unit name for data set allocations.

TUPT

This field is found in user profiles and is part of the TSO segment. It can only be used for output. It contains data from the UPT control block, which describes the user's profile settings.

This field cannot be set using the normal RACF command; it can be set using the CKGRACF FIELD command.

TVTOC

This field can only be used for SELECT/EXCLUDE processing. It corresponds to bit 2 in the RESFLG field found in TAPEVOL BASE segments. It indicates profiles with a TVTOC. It can be specified as an attribute, e.g., SELECT TVTOC. Its opposite for the purpose of SELECT/EXCLUDE processing is NOTVTOC. See also the RESFLG field.

TVTOCCNT

This field is found in GENERAL profiles and indicates the number of TVTOC entries. The entries are listed in the TVTOCSEQ, TVTOCCRD, TVTOCIND, TVTOCDSN, TVTOCVOL, and TVTOCRDS fields.

TVTOCCRD

This field is found in GENERAL profiles and indicates the creation date of a tape data set. It is a repeated field that can be combined with the TVTOCSEQ, TVTOCIND, TVTOCDSN, TVTOCVOL, and TVTOCRDS fields. The number of entries listed is in the TVTOCCNT field.

TVTOCDSN

This field is found in GENERAL profiles and indicates the RACF internal name of a tape data set. It is a repeated field that can be combined with the TVTOCCRD, TVTOCIND, TVTOCSEQ, TVTOCVOL, and TVTOCRDS fields. The number of entries listed is in the TVTOCCNT field.

TVTOCIND

This field is found in GENERAL profiles and indicates whether a discrete data set profile exists. It is a repeated field that can be combined with the TVTOCCRD, TVTOCSEQ, TVTOCDSN, TVTOCVOL, and TVTOCRDS fields. The number of entries listed is in the TVTOCCNT field.

TVTOCRDS

This field is found in GENERAL profiles and indicates the name used when creating the tape data set. It is a repeated field that can be combined with the TVTOCCRD, TVTOCIND, TVTOCSEQ, TVTOCDSN, and TVTOCVOL fields. The number of entries listed is in the TVTOCCNT field.

TVTOCSEQ

This field is found in GENERAL profiles and indicates the file sequence number of a tape data set. It is a repeated field that can be combined with the TVTOCCRD, TVTOCIND, TVTOCDSN, TVTOCVOL, and TVTOCRDS fields. The number of entries listed is in the TVTOCCNT field.

TVTOCVOL

This field is found in GENERAL profiles and indicates the volumes on which a tape data set resides. It is a repeated field that can be combined with the TVTOCCRD, TVTOCIND, TVTOCSEQ, TVTOCDSN, and TVTOCRDS fields. The number of entries listed is in the TVTOCCNT field.

UACC, UNIVACS

The Universal Access Authority of a profile. This field is found in GROUP, DATASET, and GENERAL profile types. For DATASET profiles, UNIVACS is an alias. See also the CGUACC field.

For group profiles, the UACC is NONE for all groups but VSAMDSET, where it is set to CREATE. This indicates that all users, even if they are not connected to the VSAMDSET group, are permitted to create VSAMDSET data sets.

The DATASET and GENERAL profiles can have any of the following UACC values:

- ALTER
- CONTROL
- UPDATE
- READ
- EXECUTE
- NONE

For the general resource class DIGTCERT this field has a different function. It indicates whether the digital certificate represented by the DIGTCERT profile is to be trusted (used for access). For this class the possible values are TRUST and NOTRUST.

The access given through UACC applies to all `userids`, even if they are undefined to RACF. For access given to all defined users, see `IDSTAR`.

UAUDIT

This field is found in USER BASE segments. It indicates whether the user is being audited. It can be specified as an attribute, e.g., SELECT UAUDIT. Its opposite for the purpose of SELECT/EXCLUDE processing is NOUAUDIT.

UID

This field is found in user profiles and is part of the OMVS segment. It indicates the numerical userid used for z/OS UNIX. When the `overtype` option is active, you can suffix the number with an S (e.g. 1001S), so the SHARED command keyword is added. You can also specify AUTO, which results in addition of the AUTOUID command keyword. The SHARED and AUTOUID command keywords are available in z/OS 1.4. or with APAR OW52135.

UNAME

This field is found in user profiles and is part of the NDS segment. It indicates the NDS user name. Care must be taken to ensure that this field has a unique value for each user.

UNIT

This is an alias of DEVTYPX field.

UNIVACS

This is an alias of UACC. See "UACC" on page 1204.

UNIVERSAL

This field is an alias of the UNVFLG field found in GROUP BASE segments. It indicates whether the group has the universal attribute, for example, that more than 5957 users can be connected to it. It can be specified as an attribute, e.g., SELECT UNIVERSAL. Its opposite for the purpose of SELECT/EXCLUDE processing is NOUNIVERSAL.

UNVFLG

This field is present on the group profile and is a flag byte indicating whether the group has the universal attribute, for example, more than 5957 users can be connected to it, unless they have special connect attributes. See also the UNIVERSAL and NOUNIVERSAL fields.

USEMAP

This field is found in the ICTX segment of IRR.ICTX.DEFAULTS.** profiles in the LDAPBIND general resource class. It specifies whether the Identity Context Extension (ICTX) stores an identity mapping to a local z/OS user ID when provided by the application. This field supports the `overtype` option which permits authorized users to change the value from an ISPF panel.

USER2ACS

RACF user or group id of a conditional access list entry. This is a repeated field that can be combined with the PACSCNT, PROGACS, PROGRAM, and ACL2VAR fields. Found in DATASET profiles. The number of conditional access

list entries is contained in the ACL2CNT field. The ACL combination field is the easiest way to display normal and conditional access list entries.

USERACS

This field contains the access level of an access list entry. This is a repeated field that can be combined with USERID, ACSCNT. Found in GROUP, DATASET, and GENERAL profiles. The ACLCNT field contains the number of entries.

Group profiles can have any of the following USERACS values:

- JOIN
- CONNECT
- CREATE
- USE

DATASET and general resource profiles can have any of the following USERACS values: ALTER, CONTROL, UPDATE, READ, EXECUTE, NONE.

The ACL and CONNECT combination fields are the easiest way to display this information in combination with the related fields.

USERDATA

Variable defined in C2RXDEF1 that is equivalent to USR, except that it excludes entries in use by the CKGRACF component of zSecure, queued commands, schedules, and multiple authority settings for example. See USR for subselect processing. See CKGAUTH, CKGEVENTS, CKGOTHER, CMDSEXEC, CMDSINACT, and CMDSPEND for the various CKGRACF entries.

USERDS

This is an alias of USERDSN (see "USERDSN").

USERDSN, USERDS

This field can only be used for SELECT/EXCLUDE processing. It is the complement of the FLAG1 field found in DATASET BASE segments. It indicates whether the profile covers user data sets, for example whether the high-level qualifier is a user id. It can be specified as an attribute, for example, SELECT USERDSN. Its opposite is GROUPDSN.

USERID

RACF user or group id of an access list entry. This is a repeated field of 8 characters that can be combined with USERACS, ACSCNT. Found in GROUP, DATASET, and GENERAL profiles. The ACLCNT fields lists the number of entries.

Warning: If you use this field with the USERACS field to display an access list, do *not* sort the USERID field, since the sort order of the USERACS is not changed accordingly. To display a sorted access list, use the ACL field instead.

USERNL1

This field is found in user profiles and is part of the LANGUAGE segment. It contains a 3-character code indicating the user's primary language.

USERNL2

This field is found in user profiles and is part of the LANGUAGE segment. It contains a 3-character code indicating the user's secondary language. See the USERNL1 field.

USR

The USR field is a rather special case in Security zSecure, somewhat like the ACL field. The DEFINE SUBSELECT command can be used to select only specific entries for output. See “Subselect clauses” on page 755. To select on specific combinations of values per repeat group entry, the SELECT USR(...) command can be used. See “SELECT USR(...)” on page 892.

To print just the USRDATA portion the USRDATA format can be used. See “Specifying syntax for RACF command input” on page 810.

Because entries with a `USRNM` starting with `CNG` are used for special purposes in Security zSecure, it is common to display only the other `USR` entries on many panels. See the `USERDATA` description.

As an example, to just print the USRDATA portion of the non-CNG entries one could code `userdata(usrdata,"Userdata")` in a query.

The USR field The USR field is a combination of the USRNM, USRFLG, and USRDATA fields provided by Security zSecure (the fields making up the USR field are also supported individually). Using the USR combination field instead of the individual fields has the following advantages:

- In ISPF, action characters can be used to generate CKGRACF commands to alter, copy, or delete the user fields in a profile.
- The entries used by CKGRACF are displayed in an appropriate format.
- The DEFINE command can be used to define a *subselection* of the USR field; this can be used to display only the repeat-group entries that are of interest. See “DEFINE” on page 750 for more details on subselection.

As described in the preceding paragraphs, each USR field repeat-group entry contains a USRNM field, a USRFLG field, and a USRDATA field. The USRNM field length is 8 characters long, is used as an *index*; the variable-length USRDATA field is used as the *contents*.

Security zSecure treats each USR field repeat-group entry according to its USRNM index value. All entries with an USRNM-value starting with *CNG* are treated specially. These values are reserved for use by Security zSecure. All other entries are considered installation-defined. In restricted mode, Security zSecure only grants access to those installation-defined entries to which the user is also authorized by CKGRACF. Authorization is granted using the CKGRACF profiles. See “Auditing CKGRACF” on page 371.

When the USR field is displayed, installation-defined entries are displayed in the format `USRNM USRFLG USRDATA'`. Security zSecure reserved entries are displayed in an appropriate format.

Use by Security zSecure

The CKGRACF authorized component of Security zSecure stores various types of information in the USR field of user profiles. When the USR field is displayed, these are printed in an appropriate format. This section describes the types of information stored, and the meaning of the output.

Security zSecure stores the following types of information in the USR field:

Multiple-authority settings
The multiple-authority setting determines the number of administrators required to process a CKGRACF USER command. This value is also available as the CKGMULTI field.

Default passwords
A default password is the password used by the CKGRACF

USER PWRESET and USER PWSET DEFAULT commands. Note that the default password itself cannot be displayed; its presence and the audit trail can be displayed.

Queued commands
When a user is subject to multiple-authority, a command is *queued* in the user profile until the appropriate administrators have approved (or denied) its execution. The USR field displays the queued command, a short indication of its current status, and the administrators' actions so far. The status of the queued command is also available as the CKGSTATUS field.

Scheduled revoke/resume actions
A user can be subject to multiple independent revoke/resume *schedules*, each containing revoke and resume *actions*. Each such action is stored in a USR repeat-group entry. The USR field displays the schedule name, the revoke/resume date, and the audit trail. The schedule name is also available as the CKGSCHEDULE field.

Figure 516 shows sample output of the USR field.

```
Authority setting TRIPLE set by R##PROB at 17 Feb 1994 22:07
Default password set by R##PROB at 17 Feb 1994 22:07
Queued command (R): USER CRM###3 PWDEFAULT PASSWORD;
   request by C###ROB at  4 Mar 1994 15:38
Scheduled event: Schedule 'FIRED' disable  1 Jan 1995;
   set by R##PROB at 28 Feb 1994 20:00
DBTEST   00 Installation-defined data
```

Figure 516. Sample USR fields

In the sample output, the first four entries are defined by zSecure; the last entry is installation-defined with index DBTEST. The (*R*) in the queued command indicates the current status is *request*. For a full list, see the description of the CKGSTATUS field in "SELECT and EXCLUDE" on page 884.

Action characters for the USR field

When the USR field is used in an ISPF display, action characters can be used to generate CKGRACF commands to alter, delete, or copy the USR entries. See the ISPF reference (Chapter 1, "Introduction," on page 1) for a basic description of action characters. The action characters that are permitted and the commands that are generated are dependent on the USRNM index value of the USR field. Table 406 lists the available action characters and associated action. More information about the actions is provided in the paragraphs following the table.

Table 406. Action characters and effect

Action character	Action
A	Approve a queued command
C	Create a copy of the USR entry
D	Delete a USR entry/Deny a queued command
H	Hold a queued command
I	Insert a new (blank) USR entry of the same type/index
R	Create a copy of the USR entry using ISPF panels
S	Select a USR entry for more detailed information

The action characters available are dependent on the type of USR entry:

Installation-defined USR entries
The C, D, I, and R action characters can be used with installation-defined USR entries. These commands generate a CKGRACF USRDATA command. The difference between the C and R action characters is that R prompts with an ISPF panel first, and C generates the command immediately.

Scheduled actions
The C, D, I, R, and S action characters can be used for scheduled USR actions. S displays the action in more detail. All other action characters generate a CKGRACF USER SCHEDULE command.

Queued commands
The action characters in the preceding table can be used for queued commands. The S action displays the command in more detail, including the audit trail. The A, H, and D actions approve, hold, or deny the queued command. When entered, these actions generate a CKGRACF USER command with the appropriate action. The C, I, and R actions create a new CKGRACF USER command to be requested. C immediately generates a command, I prompts with a blank ISPF panel, and R prompts with a filled-in ISPF panel.

Multiple-authority and default-password entries
No action characters can be used with multiple-authority and default-password entries.

Alternative fields to display USR data

To select profiles with USR fields, or sub-select USR repeat-group entries, a number of fields is derived from the USR field. These fields have names starting with CKG, and are described in preceding paragraphs. Beside those fields, the following fields can also be used for profile selection:

- The USRCNT field contains the number of USR entries in a profile. If the USRCNT field is zero, no USR entries can be found. A useful selection can be SELECT USRCNT>0.
- The USRNM field, which contains the index of the USR field, can be used to select profiles with relevant entries. If your installation uses the USR field with index values DB2PROJ and CICSPROJ, and you want to select those profiles with DB2PROJ entries, use SELECT USRNM=DB2PROJ. Note that the USR field still displays *all* entries in the selected profile, unless a sub-selection is used.
- The USRDATA field, which contains the contents of the USR field, can be used to select profiles with relevant contents. Because this is a variable-length field, we advise you to use the *substring scan* operator (`=:`) to search for profiles with relevant entries. If you want to find all profiles with USR fields that contain the word 'OKAYED', use SELECT USRDATA=:OKAYED. Note that the USR field still displays *all* entries in the selected profile, unless a sub-selection is used.

IBM Security zSecure Admin-specific information derived from the USR field
The following table lists the fields that describe zSecure Admin-specific information derived from the USR field. All of these fields can be used for output and profile selection. In the current version of zSecure, the date fields cannot be used for USR subselection. The **Repeated** column indicates whether the field is repeated more than once per profile. For more information, see the description of the individual fields in this section.

Table 407. IBM Security zSecure Admin-specific information derived from the USR field

Field	Type	Sub-select	Repeated	Meaning
CKGAUTHOR	Text	Yes	Yes	User who requested a queued command. Repeated for each queued command stored in the profile; undefined if the profile does not contain queued commands.
CKGCHGDATE	Date	No	Yes	Date a queued command was last changed. Repeated for each queued command stored in the profile; undefined if the profile does not contain queued commands.
CKGEXPIRY	Date	No	No	First date on which any of the queued commands expires. (Each queued command has an expire date; the earliest is taken.) Undefined if the profile does not contain queued commands.
CKGMULTI	Text	Yes	No	Multiple-authority setting.
CKGREFRESH	Date	No	No	Date after which a CKGRACF REFRESH command is required; undefined if the profile does not contain scheduled revoke/resume actions or queued commands.

Table 407. IBM Security zSecure Admin-specific information derived from the USR field (continued)

Field	Type	Sub-select	Repeated	Meaning
CKGREQUEST	Date	No	Yes	Date a queued command was requested. Repeated for each queued command stored in the profile; undefined if the profile does not contain queued commands.
CKGSCHEDULE CKGSCHED	Text	Yes	Yes	Schedule name of a scheduled revoke/resume action. Repeated for each scheduled action stored in the profile; undefined if the profile does not contain scheduled actions.
CKGSTATUS	Text	Yes	Yes	Current status of a queued command. Repeated for each queued command stored in the profile; undefined if the profile does not contain queued commands.

USRCNT

The USRCNT field is found in all profile types and describes the number of user fields. These fields are installation-reserved and are used by CKGRACF and third-party software packages. Each user field contains a USRNM index field, a USRFLG flag field, and a USRDATA contents field. The field is also available as the USR combination field.

USRDATA

The USRDATA field is found in all profile types and contains the contents part of the 'user fields' repeat group. See also the USR and USRCNT fields.

USRFLG

The USRFLG field is found in all profile types and contains the flag part of the 'user fields' repeat group. See also the USR and USRCNT fields.

USRNM

The USRNM field is found in all profile types and contains the index part of the 'user fields' repeat group. See also the USR and USRCNT fields.

UUID

This field is found on the DCE segment of the user profile. It contains the universal unique identifier of the principal. The UUID is exactly 36 characters, in the format *nnnnnnnn-nnnn-nnnn-nnnn-nnnnnnnnnnnn* where n is any hexadecimal digit.

VERSION

Profile/template version number.

VOL

This is an alias of VOLSER (see "VOLSER").

VOLCNT

For DATASET and GENERAL profiles, this field specifies the number of volumes containing the tape data set. The volume serials are listed in the VOLSER field.

VOLSER, VOLUME, VOL

For DATASET and general resource profiles, this repeated field lists the volume serials of the volumes containing the (tape) data set. The number of volume serials is listed in the VOLCNT field.

The VOL field name can only be used for SELECT/EXCLUDE processing.

VOLUME

This is an alias of VOLSER (see "VOLSER").

VSAM

This field can only be used for SELECT/EXCLUDE processing. It corresponds to bit 0 in the DSTYPE field found in DATASET BASE segments. It indicates whether the profile is a VSAM data set profile. It can be specified as an attribute, e.g., SELECT VSAM. Its opposite for the purpose of SELECT/EXCLUDE processing is NONVSAM. See also the DSTYPE field.

WAACCNT

This field is found in user profiles and is part of the WORKATTR segment. It indicates the account number for APPC/MVS processing.

WAADDR1

This field is found in user profiles and is part of the WORKATTR segment. It indicates SYSOUT delivery address line 1.

WAADDR2

This field is found in user profiles and is part of the WORKATTR segment. It indicates SYSOUT delivery address line 2.

WAADDR3

This field is found in user profiles and is part of the WORKATTR segment. It indicates SYSOUT delivery address line 3.

WAADDR4

This field is found in user profiles and is part of the WORKATTR segment. It indicates SYSOUT delivery address line.

WABLDG

This field is found in user profiles and is part of the WORKATTR segment. It indicates the building for delivery.

WADEPT

This field is found in user profiles and is part of the WORKATTR segment. It indicates the department for delivery.

WANAME

This field is found in user profiles and is part of the WORKATTR segment. It indicates the user name for SYSOUT delivery.

WARN

This is an alias of WARNING (see "WARNING").

WARNING, WARN

This field is found in the BASE segment of DATASET and GENERAL profiles and indicates whether the data set or resource has the WARNING attribute, which indicates whether access is granted even if the access level requested is higher than the one permitted by other profile settings. This is a non-standard field because bit 7, not bit 0, is used. The alias WARN can only be used for SELECT/EXCLUDE processing. It can be specified as an attribute, SELECT WARNING for example. Its opposite for the purpose of SELECT/EXCLUDE processing is NOWARNING.

WAROOM

This field is found in user profiles and is part of the WORKATTR segment. It indicates the room for delivery.

WORKATTR

This field can only be used for SELECT/EXCLUDE processing. It selects WORKATTR segments.

X509REGISTRY, X509REG

This field is found in the EIM segment of LDAPBIND and FACILITY class general resource profiles. On the IRR.PROXY.DEFAULTS profile in the FACILITY class it specifies the name of the X.509 registry in the EIM domain that the system is configured to use. On other profiles it is ignored. This field supports the `overtype` option.

XRFSOFF

This field is found in user profiles and is part of the CICS segment. It is a flag field indicating whether CICS is to sign-off the operator following an XRF takeover.

RACF_ACCESS: Connects and permits

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•		

The `RACF_ACCESS NEWLIST (NEWLIST TYPE=RACF_ACCESS)` provides information about the permits and connects used for RACF access. The input data for this `NEWLIST` type can be both the RACF database records and the Access Monitor summary

data sets which consolidate the actual access events logged over a given time interval. Alternatively, you can use the SIMULATE RACF_ACCESS command to limit the input to the RACF database records.

If you use both the RACF database and the Access Monitor summary data, the report provides information on actual permits and connect use.

If you use the RACF_ACCESS NEWLIST in combination with the SIMULATE_RACF_ACCESS option, the report provides information on the permits and connects allowed based on the RACF database profile definitions. The output is an exploded view of all permits and connects defined in the RACF database, including the effect of RACLIST merge processing.

A record in RACF_ACCESS NEWLIST output can contain any of the following types of access information:

- A permit for a profile or profile member.
- A connect for a profile or profile member.
- A group authority for a profile or profile member.

Grouping profile members are only present as separate records for RACLISTed grouping classes,

For SETROPTS or GLOBAL=YES RACLIST-ed classes, permits per member profile or grouping profile member might be present twice because the RACLIST merge result is also returned for records that have the flag RACLIST_MERGE set on.

Access counts for each access event are increased based on the following rules:

1. If SIMULATE RACF_ACCESS is not used, access events found in Access Monitor records saved in the Access Monitor summary data are counted under the profile implied by the access summary records as long as the profile key is still present in the RACF database. If a profile key is present in the access summary data but is no longer present in the specified RACF input source, the access is counted against a missing profile. In the RACF_ACCESS NEWLIST output, these types of access are listed as proftype=missing.
2. If SIMULATE RACF_ACCESS is specified, you can observe what the recorded RACF access decisions would have been, based on the specified RACF input source.

Important:

If you run a NEWLIST type=RACF_ACCESS command concurrently with a NEWLIST type=ACCESS command, the SIMULATE specification for NEWLIST TYPE=RACF_ACCESS takes precedence over the use of SIM_* fields in the NEWLIST TYPE==ACCESS. If you specify NEWLIST TYPE=RACF_ACCESS with the SIMULATE RACF_ACCESS setting, the SIM_* fields are present. If you run NEWLIST TYPE=RACF_ACCESS without the SIMULATE RACF_ACCESS setting, all SIM_* fields in the NEWLIST TYPE=ACCESS is reported as missing. For more information on the ACCESS NEWLIST type, see "ACCESS: Access Monitor Records" on page 953.

Field descriptions

The RACF_ACCESS NEWLIST provides the following fields for reporting.

ACCESS

Indicates the type of access. The following types are reported:

- ACL access for a permit.

- The connect authority for a connect.
- QUALOWN for access authority through a data set High-level qualifier.

The default field width is 9 characters.

ACCESS_COUNT_SUCC

Count of successful accesses as counted for this entry. Successful access is counted for all possible ways the user has access to the resource because the system does not determine which method is actually used by RACF. The maximum count is 2**32-1. When the maximum count has been reached, the count is not increased even if additional access events are found in the access records.

Note: This field is only supported if zSecure Admin is installed and active. In environments that only have zSecure Audit, the fields are shown as missing (blank).

ACCESS_COUNT_UNK

Count of accesses that cannot be explained by this access record entry. For example, an unknown access can be a result of an access summary record that shows successful access events that are higher than the permit access level on a user permit, or that shows a violation where the current RACF database indicates that the access permit level should have resulted in access being granted. The number has a ceiling of 65535. When the maximum count has been reached, the count is not increased even if additional unknown access events are found in the access records.

Note: This field is only supported if zSecure Admin is installed and active. In environments that only have zSecure Audit, the fields are shown as missing (blank).

ACCESS_COUNT_VIO

Count of violations that this access record entry might have caused. The number has a ceiling of 65535. When the maximum count has been reached, the count is not increased even if additional unknown access events are found in the access records.

Note: This field is only supported if zSecure Admin is installed and active. In environments that only have zSecure Audit, the fields are shown as missing (blank).

ACCESS_FIRSTUSE

The Access Monitor data collection only tracks `ACCESS_LASTUSE`. For example, if a particular access specification is used five times a day, the daily consolidation access summary file shows the last time the access specification was used during that day. If the current `RACF_ACCESS` report uses multiple daily consolidation files, the last use data for each individual daily consolidation file is the `ACCESS_LASTUSE` value recorded for each day. The `ACCESS_FIRSTUSE` field stores the value of the earliest occurrence of the `ACCESS_LASTUSE` value in all the consolidation files.

If the current `RACF_ACCESS` report uses a single Access Monitor summary file, the `ACCESS_FIRSTUSE` value is the same as the `ACCESS_LASTUSE` value in the summary file.

ACCESS_INTENT_MAX_SUC

Indicates the highest allowed access intent found in the access summary. For example, on an UPDATE permit record where the user read data, the field value is READ.

ACCESS_INTENT_MIN_VIO

Shows the lowest access violation level found in the access summary.

ACCESS_LASTUSE

Shows the date and time of last use in TOD clock format.

ACCESS_REDUCED

Flag field that indicates whether the access level granted to ID is less than the access granted using any of the GROUPS that ID is a member of, the access granted to ID(*), or the UACC.

If ID is a group, ACCESS_REDUCED=YES when the access granted by ID(*) or by UACC is higher than that granted by the group.

For ID(*), ACCESS_REDUCED=YES if its access is less than that granted by the UACC.

CLASS

Provides the 8-character RACF profile class for the profile listed in the PROFILE field. See "PROFILE" on page 1217.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

GENERIC

Flag field that shows if the profile is generic.

ID

The ACL ID for a permit, or a connected user ID for a GROUP profile, or one of the special values listed in Table 408.

Table 408. RECORD Types for NEWLIST TYPE=ACCESS

Value	Description
-UACC-	Reflects the Universal Access attribute which means that even undefined users can access the record.
- any -	Reflects access provided through the global access table which means that even undefined users can access the record.
-other-	Reflects the access level for a missing profile to count accesses.
-error-	Unexpected condition - low priority program defect.

MEMBER_CLASS

For a grouping profile member, this field provides the member class.

For grouping class profile records, a single grouping class profile is represented by multiple RACF_ACCESS records: One record describes the grouping profile itself. The remaining records describe the members. The MEMBER_CLASS for the grouping profile record is the name of the grouping class. For the multiple records describing the members, the MEMBER_CLASS is the name of the class that is linked to the grouping class (the member class).

For a non-grouping class profile the value of MEMBER_CLASS is the same as that of CLASS.

MEMBER_KEY

Shows the member key for a grouping profile member.

For grouping class profile records, a single grouping class profile is represented by multiple records. One record describes the grouping profile itself. The other records describe the members. The MEMBER_KEY for the grouping profile record is the same as the profile key in the PROFILE field. The MEMBER_KEY for the member records contains the member name.

For non-grouping class profile records, MEMBER_KEY always has the same value as the PROFILE field.

The MEMBER_KEY field represents the member key in human readable form which means that the generic member keys are sorted alphabetically and cannot be sorted by generic search order.

MERGED_ACCESS_REDUCED

Flag field that indicates if the access level granted to ID is less than that granted using any of the less specific access list entries in the profiles used during merge of grouping and member profiles. For example, if ID is a userid with READ and another merged grouping class profile specifies ID(*) with UPDATE, the access level READ is reduced from what the userid would have if access READ was not specified.

MERGED_ACCESS_REDUCED is similar to ACCESS_REDUCED except that the access specifications used to determine the value of MERGED_ACCESS_REDUCED can be taken from different profiles that are merged during the RACF RACLIST process. For the ACCESS_REDUCED field, the value is determined by access specifications for the same profile.

This field is missing for non-grouping resource classes and for records with RACLIST_MERGE=YES.

PROFILE

The PROFILE field provides the profile key in human readable form. Because the value is human readable, the RACF_ACCESS NEWLIST type does not allow you to sort the generic profiles by generic search order. The default width for this field is 44, the maximum length is 246.

For the profile class, see "CLASS" on page 1216.

PROFTYPE

Shows the profile type. Table 409 lists the available types.

Table 409. Profile Types for NEWLIST TYPE=RACF_ACCESS

Profile Type	Description
connect	Connect record.
DISCRETE	Discrete general resource profile record.

Table 409. Profile Types for NEWLIST TYPE=RACF_ACCESS (continued)

Profile Type	Description
GENERIC	Generic data set or general resource profile record.
GLOBAL	Global access table entry record.
GROUPING	Member in a grouping profile record.
missing	Indicates that a profile key is present in the access summary data but the profile key is no longer present in the specified RACF database input source.
MODEL	Model profile record.
NONVSAM	Discrete non-VSAM DATASET profile record.
TAPEDSN	Discrete tape data set profile record.
VSAM	Discrete VSAM profile.

QUALIFIED_RESOURCE

This field concatenates values in the RESOURCE_LOCATION and RESOURCE fields (separated by a colon) and shows which transaction name is defined in which region. It has a default length of 64 characters and a maximum length of 282 characters. An example value is IPO1.CICS.CICSTS41.TRN:CEMT. The format is as follows:

system.subsys-type.subsys-identification.restype:<resource>

Note: The maximum number of entries is the product of the number of entries in these two fields. If there are 10 resource names and 20 resource locations, the QUALIFIED_RESOURCE field might contain as many as 200 entries.

RACLIST_MERGE

Flag field that indicates whether the record is part of the RACLIST merge result. When the flag value is `YES`, the record represents the in-storage profile built during the RACF RACLIST process. If you only want to see basic database permits and connects, filter the report results using `RACLIST_MERGE=NO`.

Note:
The RACLIST process is used by RACF either during the SETROPTS RACLIST command processing or when an application that starts `RACROUTE REQUEST=LIST,GLOBAL=YES.`

RESOURCE

Select or show the names of resources that match the permit. The RESOURCE field shows only those resources that are effectively protected by the permit to the PROFILE. For RACLISTed resource classes, the RACLIST merge process can result in overruling the access specified in one grouping class profile by a (higher) access specified in another grouping or member class profile. If access is overruled, the RESOURCE field for the PROFILE is empty. For other IDs, an access overrule might not apply and the RESOURCE field includes all applicable resources.

You can also automatically include which sensitive resources or data sets are covered by each profile using the command `REPORT RESOURCE` or `REPORT DATASET`, respectively. To include both types, specify the command `REPORT RESOURCE DATASET`. Before using these options, consider the amount of output that will be generated, especially when including data sets. Without any further

SELECT statements, these options cause a combinatorial explosion of the number of resources in the system times the number of permits in the profiles that cover them. The volume of output generated might exceed acceptable job output size at your site. You can issue the SUPPRESS AUTO_RESOURCE command to limit the report to resources for which you have issued a SIMULATE CLASS or SIMULATE RESOURCEcommand or a SIMULATE SENSITIVE command.

RESOURCE_LOCATION

Identifies the resource name environment. This repeat group field includes the RESOURCE_LOCATION field only. The default and maximum length is 35 characters. An example value with four qualifiers is IPO1.CICS.CICSTS41.DATASET. The SIMULATE command automatically generates resource names. Names can include two or four qualifiers. The *subsys-identification* and *restype* qualifiers are optional. The format is as follows:

system.subsys-type.subsys-identification.restype

If you want to see which transaction name is defined in which CICS region, use the QUALIFIED_RESOURCE field in your report instead of using the RESOURCE and RESOURCE_LOCATION fields. The RESOURCE_LOCATION repeat group produces results that are independent of the RESOURCE field even though the results might appear related if these fields appear side-by-side in a report.

VOLSER

Shows the first volume serial. This field is only present for discrete VSAM, non-VSAM, and tape DATASET profiles.

REPORT_AC1: Authorized module protection

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	

The REPORT_AC1 NEWLIST (NEWLIST TYE=REPORT_AC1) only reports on the default system. The default system is set using the DEFAULT command.

This NEWLIST has been built to audit the protection of programs that run with a system-level authorization and are callable by users that do not yet have such an authorization level. Penetrating the security built into those programs usually yields total control over the operating system to a *normal* user. This makes these programs a target for hackers. For a list of the authorizations checked see the AUTH field.

A CKFREEZE file is required and must include PDS directory information for this function. This means that zSecure Collect must be run on z/OS with the proper focus. The focus will automatically be OK if you run zSecure Collect with the same entitlements as CKRCARLA. If you are analyzing a CKFREEZE file created on z/OS with different entitlements or a specific focus, you must be aware that for REPORT AC1 the focus must include at least one of AUDITRACF, AUDITACF2, or ADMINRACF. It must also be run APF authorized or non-APF authorized with PDS=YES added and sufficient access on *all* linklist and APF data set directories. When run without APF authorization, PPT information and module information where the CKFCOLL caller has no read access will be missing.

The CARLa script CKRRAC1 containing this NEWLIST type is included automatically by the REPORT AC1 command if the NEWLIST type was not yet specified in the input above the REPORT command.

Field descriptions

The REPORT_AC1 NEWLIST provides the following fields for reporting.

AUTH

This repeat group field indicates sources of authorization for the module. Table 410 provides the value and description for the authorization source type that can be reported.

Table 410. TYPE=REPORT_AC1 - AUTH parameter values for module authorization source types

Authorization source type	Description
AC=1:Bypass	RACF and password security, from the Program Property Table (PPT).
AuthCMD	Can be called as TSO authorized command.
AuthPGM	Can be called under TSO as an authorized program.
AuthTSF	Can be called as authorized through the TSO service facility.
IEAAPP00	I/O appendage that is authorized for use by non-APF users
Key=n	System key from the PPT.
RACINIT	from RACF authorized caller table ICHAUTAB
RACLIST	from ICHAUTAB.
Signed	The signed attribute bit is on in the PDSE directory entry for the module. The Signed attribute bit being on does not mean that the signature is valid or even present.
SigProb	A problem occurred when the zCollect program (CKFCOLL) attempted signature verification.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

DSN

Contains the name of the data set where the module resides or presumably was loaded from (for LPA modules). In addition, it can contain the string '*** LPA

' to indicate that it was present in the link pack area in-storage but that no corresponding load module name was found in an LPA data set. Also, it can contain the string ' module not found ***' to indicate that it was not found in the link pack area in-storage nor in any PDS.

HIDDEN_LINKLIST

This is a flag that indicates that this module is hidden from view in the link list (for example, in the concatenation, a different module will be loaded).

HIDDEN_LPALIST

Flag field that indicates if this module is hidden from view in the LPA list. That is, in the concatenation, a different module is loaded.

LINKLIST

Concatenation number of the module's data set in the current link list set. It might be empty to indicate the module is not in the current link list set.

LPALIST

Concatenation number of the module's data set in the LPA list. It might be empty to indicate the module is not in the LPA list.

LPA_TYPE

One-character field that can have one of the following values: `F` for Fixed Link Pack Area, `M` for Modified Link Pack Area, `P` for Pageable Link Pack Area, or blank if the module is not in the LPA

MEMBER

Returns the member name that contains the load module for the program, or the major name of a module in-storage where the actual member could not be found in a PDS directory.

MODULE

Returns the name of a program entry point that is available in the system. It is not necessarily equal to the member name, a load module can contain more than one program entry point.

ORDER

Returns a number that when sorted corresponds to the sort order designated by the REPORT BY= parameter. It can be used with the modifier NONDISPL to implement the REPORT BY= parameter.

PAGEBY

Returns a number that increases at each page break implied by the REPORT PAGEBY= parameter. It can be used with the modifiers PAGE,NONDISPL to implement the REPORT PAGEBY= parameter.

PROGRAM

Returns the name of a RACF PROGRAM profile if it covers the program when loaded from a data set. Note that an LPA module is not subject to program control in its already loaded form, although it is considered to be a 'controlled' program anyway.

PROGRAM_TYPE

Since z/OS V1.4, RACF can run in Enhanced program security mode. In this mode, a program can be defined as MAIN or BASIC program. This field returns the type of the program.

PROFILE

Returns the name of the RACF DATASET profile that protects the load library where the load module member resides.

STAMP

Returns the unload time stamp of the security database.

SYSTEM

Returns the name of the system this report pertains to. The REPORT_AC1 NEWLIST describes only one system, the default system. It can be changed by the DEFAULT command.

UACC

For a RACF system, this field contains the consolidated universal access for the program. To arrive at this universal access, a number of questions are first answered internally to get a full picture of the protection. These are:

1. (RACF) Do the DATASET profiles covering the APF data sets containing the module have UACC(NONE)?
2. (RACF) Is the module covered by a PROGRAM profile in all data sets?
3. (RACF) Does the PROGRAM profile have UACC(NONE)?
4. Is one of the APF data sets part of the linklist concatenation?
5. Which (APF or non-APF) data set is the first in the linklist concatenation to contain the module?
6. Is the module present in LPA?
7. Is the module present in MLPA?
8. (RACF) Is the data set covered by a global access table entry with READ or higher?
9. (RACF) Is the data set profile in warning mode?

The program determines the answers to these questions, and deduces the resulting universal access to the module, showing EXECUTE or higher if anybody (not explicitly denied access) can execute it. This column can display some special access levels not normally defined by the security package. The following table shows all possible UACC levels.

Table 411. UACC levels and descriptions

UACC level	Description
ALTER	The data set UACC allows ALTER to any task or user in the system. This is a major leak.
AD-UPD-NX	The data set UACC allows ALTER to any task or user in the system, but the program is not directly executable because the PROGRAM profile UACC is NONE. This is a major leak.
UPDATE	The data set UACC allows UPDATE to any task or user in the system. This is a major leak.
UPD-NX	The data set UACC allows UPDATE to any task or user in the system, but the program is not directly executable because the PROGRAM profile UACC is NONE. This is a major leak.
READ	The data set UACC allows READ to any task or user in the system. This makes it vulnerable to analysis by a hacker.
READLPA	The data set UACC does not allow READ, but module can be read in LPA. This makes it vulnerable to analysis by a hacker.

Table 411. UACC levels and descriptions (continued)

UACC level	Description
LOADEXE	The data set UACC does not allow READ, but the module can be executed, and it can be read by issuing LOAD (this requires that you know the module name).
EXECUTE	The data set UACC does not allow READ, and the module can only be executed in a controlled environment.
COPY	The module can be read, but it cannot be executed. If its operation does not depend on APF or library residence (PADS), anyone can access its functionality by copying it to his own load library.
HIDDEN	The module UACC is NONE, because it is hidden by a similar-named module concatenated in front of the LPA or linklist concatenation.
NONE	The module UACC is NONE. It is only available to specifically authorized users or groups.

Note: Since z/OS V1.4, modules protected by the `*` or `**` `PROGRAM` profile and read from `SYS1.LINKLIB` can always be executed. In effect, those `PROGRAM` profiles have at least `UACC(READ)`.

VOLSER

Contains the volume serial where the data set indicated in DSN resides.

REPORT_NONDEFAULT: RACF profiles changed from default

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•		

For group data sets, this lists 'out-of-group' access as discussed in “REPORT_OUTOFGROUP: RACF profiles accessible outside group” on page 1226 as well as 'out-of-group' access where the 1st qualifier is another group than the OWNER. However, userids in the access list are not checked for connects, but always marked as non-default, unless they are equal to either the OWNER or the 1st qualifier (an explicit PERMIT command must have been used to create this situation, and in this sense they are non-default).

In addition, user data set profiles are listed where other people than the owner are in the access list or in the OWNER field (or UACC not equal to NONE). The profiles can be augmented with the actual data sets they cover by making sure the REPORT DATASETS option is present.

The CARLa script CKRRNDEF containing this NEWLIST type is included automatically by the REPORT NONDEFAULT command if the NEWLIST type was not yet specified in the input above the REPORT command.

Field descriptions

The `REPORT_NONDEFAULT NEWLIST` provides the following fields for reporting.

ACCESS

Repeat group field that returns the access level column of the annotated combined access list defined by MARK, ID, ACCESS, and PROGRAM.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

ID

Repeat group field that returns the user or group ID column of the annotated combined access list defined by MARK, ID, ACCESS, and PROGRAM.

KEY

Repeat group field that returns the RACF profile name followed by the data set names that it covers. The data set names are only present when the `REPORT DATASETS` parameter has been requested.

MARK

Repeat group field that returns the annotation column of the annotated combined access list defined by MARK, ID, ACCESS, and PROGRAM. This field contains an arrow '->' to highlight a specific access list entry that is not default.

ORDER

Returns a number that when sorted corresponds to the sort order designated by the REPORT BY= parameter. It can be used with the modifier NONDISPL to implement the REPORT BY= parameter.

PAGEBY

Returns a number that increases at each page break implied by the REPORT PAGEBY= parameter. It can be used with the modifiers PAGE, NONDISPL to implement the REPORT PAGEBY= parameter.

PROFTYPE

Part of a repeat group with the KEY and VOLUME fields, this field returns the RACF profile type (GENERIC, NONVSAM, TAPE, MODEL) for the first or only line, and the data set type for subsequent lines. For a list of data set types, see "PROFTYPE" on page 1244.

PROGRAM

Repeat group field that returns the program conditional access column of the annotated combined access list defined by MARK, ID, ACCESS, and PROGRAM.

QUAL

Indicates the first qualifier of the data set profile as modified by ICHCNX00 and ICHNCV00. This value can be used to group related profiles together on separate pages.

REASON

Returns a reason why the profile is considered to be a non-default profile. There might be more reasons, but only one is spelled out. However, *all* access list entries present that are considered non-default are marked with an arrow in the field MARK. The reasons that can be present are:

Table 412. Reason field values and descriptions

Reason	Description
Conditional access	An entry in the conditional access list is always considered non-default.
Group access	The owning group or the data set's 1st qualifier group must be in the access list of a group data set profile to be considered default. In addition, the access must be either ALTER or UPDATE. ALTER is the preferred way, especially in a generic profile environment with PROTECTALL active, since data set creation is otherwise impossible. However, the RACF default set by the GRPACC attribute is UPDATE, therefore this is considered default, too. The entry will be marked with an arrow unless it is missing from the access list.
Missing access	To be considered default, access must be granted either to the first qualifier identity or to the owner, either implicitly (e.g. 1st qualifier is a userid) or explicitly (by means of an access list entry).
More than 1 group	For an access list to be considered default, it might contain only one group, either the 1st qualifier group or the owning group. Other groups are marked with an arrow.
Not owner or group	An identity in the access list is only considered default if it is the owner, or if it is a group and equal to the 1st qualifier. An undefined identity is never considered default. The identity is one of the entries marked with an arrow.
Owner access not ALTER	To be considered default, the identity owning the profile must have ALTER access to his data.
Owner not in group	The owner of a group data set profile is a user without connect to the group. Note that the notion of data set groups presupposes that ownership is a user group, not a user.
Universal access	UACC is unequal to NONE, giving access outside the group.
User not owner	The data set name starts with a userid. To be considered default, the data set profile owner must be that userid.

STAMP

Returns the unload time stamp of the RACF database. It cannot be used for SELECT and EXCLUDE processing.

UACC

Returns the universal access of the profile.

VOLSER

A repeat group field that combines with the KEY field. On the first or only line of an entry, this field shows the volume serial of the RACF profile in the KEY field. This value is only provided for discrete profiles. In the next lines it shows the volume serial where the data sets in the corresponding lines of KEY reside. The latter are only present when the REPORT DATASETS option has been requested.

REPORT_OUTOFGROUP: RACF profiles accessible outside group

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•		

The REPORT_OUTOFGROUP NEWLIST (NEWLIST TYPE=REPORT_OUTOFGROUP results in a display of group data set profiles that have a UACC other than NONE, or an OWNER or access list entry for a user or group outside the group indicated by the first qualifier as modified by ICHCNX00 and ICHNCV00.

The report can be used by sites that have a simple RACF group structure with both user and data set profiles, to get a small report of profiles with a 'non-standard' access list, as opposed to a complete list of all profiles. This is especially useful in all-discrete environments, where typically most of the profiles have a default layout.

For sample output see "RA.3.5 OUT OF GROUP - Group data sets that can be accessed from outside the group" on page 212.

The CARLa script CKRROUTG containing this NEWLIST type is included automatically by the REPORT OUTOFGROUP command if the NEWLIST type was not yet specified in the input above the REPORT command.

Field descriptions

The REPORT_OUTOFGROUP NEWLIST provides the following fields for reporting.

ACCESS

This repeat group field returns the access level column of the annotated combined access list defined by MARK, ID, ACCESS, and PROGRAM.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

ID

Repeat group field that returns the user or group ID column of the annotated combined access list defined by MARK, ID, ACCESS, and PROGRAM.

KEY

Repeat group field that returns the RACF profile name followed by the data set names that it covers. The data set names are only present when the REPORT DATASETS parameter has been requested.

MARK

Repeat group field that returns the annotation column of the combined access list defined by MARK, ID, ACCESS, and PROGRAM. The field contains an arrow '->' to highlight the specific access list entry that points out of the group.

ORDER

Returns a number that when sorted corresponds to the sort order designated by the REPORT BY= parameter. It can be used with the modifier NONDISPL to implement the REPORT BY= parameter.

PAGEBY

Returns a number that increases at each page break implied by the REPORT PAGEBY= parameter. It can be used with the modifiers PAGE,NONDISPL to implement the REPORT PAGEBY= parameter.

PROFTYPE

This field is part of a repeat group with the KEY and VOLUME fields. IN the first or only line in the listing, the value represents the RACF profile type (GENERIC, NONVSAM, TAPE, or MODEL). For subsequent lines, it provides the data set type. For a list of data set type see "PROFTYPE" on page 1244.

PROGRAM

Repeat group field that returns the program conditional access column of the annotated combined access list defined by MARK, ID, ACCESS, and PROGRAM.

QUAL

Field that indicates the first qualifier of the data set profile as modified by ICHCNX00 and ICHNCV00. The field can be used to group related profiles together on separate pages.

REASON

Field that indicates the first reason why a profile was included in the report. There might be more reasons, but only one is spelled out. However, all access list entries referring outside the data set 1st-qualifier group are marked with an arrow in the field MARK. Table 413 lists the possible values for the REASON field.

Table 413. REPORT_OUTOFGROUP: Reason field values and descriptions

Value	Description
Universal access	UACC is unequal to NONE, giving access outside the group.
User not in group	A user in the access list or OWNER field is not connected to the data set's 1st qualifier group. If it is a user in the access list, the user is one of the entries marked with an arrow.
Other group	A group in the access list or OWNER field was present different from the data set's 1st qualifier group. If the group is part of the access list, it is one of the entries marked with an arrow.

STAMP

Returns the unload time stamp of the RACF database. This field cannot be used for SELECT or EXCLUDE processing.

UACC

Returns the universal access of the profile. This field supports overtype.

VOLSER

Repeat group field with the KEY field that shows the volume serial of the RACF profile in the KEY field on the first or only line for an entry. The value is only listed for discrete profiles. In the next lines the volume serial where the data sets in the corresponding line of KEY reside. The latter are only present when the REPORT DATASETS option has been requested.

REPORT_PADS: Programs giving access to data sets

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•		

The REPORT_PADS NEWLIST (NEWLIST TYPE = REPORT_PADS) is used for auditing the protection of programs that grant additional access to another data set when they are run. These programs occur in the conditional access list of some data set profile. For RACF, this type of access is known as PADS, Program Access to Data Sets (PADS). PADS programs are included in the conditional access list of some data set profile. Penetrating the security built into those programs usually yields control over some application, unless the data set is part of the Trusted Computing Base, in which case the operating system might be compromised. These programs are a potential target for hackers, although they are less tempting than the programs reported by the REPORT_AC1 NEWLIST.

This REPORT_PADS NEWLIST only reports on the default system. The default system can be set with the DEFAULT command. Using the REPORT_PADS NEWLIST requires CKFREEZE data that includes PDS directory information. This means that zSecure Collect must be run on a z/OS system that running zSecure Audit for RACF (zSecure Collect parameter settings FOCUS=AUDIT and FOCUS=RACF.

A CKFREEZE file is required and must include PDS directory information for this function. zSecure Collect must also be run APF authorized or non-APF authorized with the PDS=YES parameter added and sufficient access on *all* link list and APF data set directories. If the data collection is run without APF authorization, the data does not include PPT information and module information where the CKFCOLL caller has no read access.

The CARLa script CKRRPADS containing this NEWLIST is included automatically by the REPORT PADS command if the NEWLIST type was not yet specified in the command input that precedes the REPORT command.

Field descriptions

The REPORT_PADS NEWLIST field provides the following values.

AUTH

Repeat group field that indicates additional sources of authorization for the module (besides PADS). It can be *AC=1 Bypass* (bypass RACF and password security, from Program Property Table PPT), *Key=n* (system key, from PPT), *RACINIT* (from RACF authorized caller table ICHAUTAB), *RACLIST* (from ICHAUTAB), *AuthCMD* (can be called as TSO authorized command), *AuthPGM* (can be called under TSO as an authorized program), *AuthTSF* (can be called as authorized through the TSO service facility), and *IEAAPP00* (I/O appendage that is authorized for use by non-APF users).

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

DSN

Contains the name of the data set where the module resides or presumably was loaded from (for LPA modules). In addition, it can contain the string '*** LPA ***' to indicate that it was present in the link pack area in-storage but that no corresponding load module name was found in a LPA data set. Also, it can contain the string '*** module not found ***' to indicate that it was not found in the link pack area in-storage nor in any PDS.

HIDDEN_LINKLIST

Flag field that indicates if this module is hidden from view in the link list. That is, in the concatenation, a different module is loaded.

HIDDEN_LPALIST

Flag field that indicates if this module is hidden from view in the LPA list. That is, in the concatenation, a different module is loaded.

LINKLIST

Concatenation number of the data set for the module in the current link list set. This field might be empty to indicate the module is not in the current link list set.

LPALIST

Concatenation number of the data set for the module in the LPA list. This field might be empty to indicate the module is not in the LPA list.

LPA_TYPE

This one character field can have the following values: `F` for Fixed Link Pack Area, `M` for Modified Link Pack Area, `P` for Pageable Link Pack Area, or blank if the module is not in the LPA.

MEMBER

Returns the member name that contains the load module for the program, or the major name of a module in-storage where the actual member could not be found in a PDS directory.

MODULE

This field returns the name of a program entry point that is available in the system. It is not necessarily equal to the member name (a load module can contain more than one program entry point).

ORDER

Returns a number that when sorted corresponds to the sort order designated by the REPORT BY= parameter. It can be used with the modifier NONDISPL to implement the REPORT BY= parameter.

PAGEBY

Returns a number that increases at each page break implied by the REPORT PAGEBY= parameter. It can be used with the modifiers PAGE,NONDISPL to implement the REPORT PAGEBY= parameter.

PROGRAM

Returns the name of a RACF PROGRAM profile if it covers the program when loaded from a data set. Note that an LPA module is not subject to program control in its already loaded form, but it is considered controlled anyway.

PROGRAM_TYPE

Since z/OS V1.4, RACF can run in Enhanced program security mode. In this mode, a program can be defined as MAIN or BASIC program. This field returns the type of the program.

PROFILE

Returns the name of the DATASET profile that protects the load library where the load module member resides.

STAMP

Returns the unload time stamp of the RACF database. It cannot be used for SELECT/EXCLUDE processing.

SYSTEM

Returns the name of the system this report pertains to. The REPORT_PADS NEWLIST describes only one system, the default system. It can be changed by the DEFAULT command.

UACC

For a RACF system, this field contains the consolidated universal access for the program. To arrive at this universal access, the following questions are first answered internally to get a full picture of the protection:

1. (RACF) Do the DATASET profiles covering the APF data sets containing the module have UACC(NONE)?
2. (RACF) Is the module covered by a PROGRAM profile in all data sets?
3. (RACF) Does the PROGRAM profile have UACC(NONE)?
4. Is one of the APF data sets part of the linklist concatenation?
5. Which (APF or non-APF) data set is the first in the linklist concatenation to contain the module?
6. Is the module present in LPA?
7. Is the module present in MLPA?
8. (RACF) Is the data set covered by a global access table entry with READ or higher?
9. (RACF) Is the data set profile in warning mode?

The program determines the answers to these questions, and deduces the resulting universal access to the module, showing EXECUTE or higher if anybody (not explicitly denied access) can execute it. This column can display some special access levels not normally defined by the security package. The following table shows the whole range between NONE and UPDATE.

Table 414. REPORT_PADS: UACC level and description

UACC level	Description
UPDATE	The data set UACC allows UPDATE to any task or user in the system. This is a leak.

Table 414. REPORT_PADS: UACC level and description (continued)

UACC level	Description
READ	The data set UACC allows READ to any task or user in the system. This makes it vulnerable to analysis by a hacker.
READLPA	The data set UACC does not allow READ, but module can be read in LPA. This makes it vulnerable to analysis by a hacker.
LOADEXE	The data set UACC does not allow READ, but the module can be executed, and it can be read by issuing LOAD (this requires that you know the module name).
EXECUTE	The data set UACC does not allow READ, and the module can only be executed in a controlled environment.
COPY	The module can be read, but it cannot be executed. If its operation does not depend on APF or library residence (PADS), anyone can access its functionality by copying it to his own load library.
HIDDEN	The module UACC is NONE, because it is hidden by a similar-named module concatenated in front of the LPA or linklist concatenation.
NONE	The module UACC is NONE. It is only available to specifically authorized users or groups.

VOLSER

Contains the volume serial where the data set indicated in DSN resides.

REPORT_PROFILE: RACF profiles and data sets

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•		

The `REPORT_PROFILE NEWLIST` is a predefined report for listing the most-used fields of profiles that you select. It is automatically included by the `REPORT PROFILES` command. In addition, you can request the names of data sets covered by the profile to be added. Contrary to the `LD DSNS` parameter in RACF, this also includes uncataloged data sets, the original data set names for backed-up discrete profiles, and single-qualifier data set names. This is requested by adding the `DATASETS` parameter to an existing `REPORT` command or by adding a `REPORT DATASETS` command after your NEWLIST requests.

The CARLa script CKRRPROF containing the `REPORT_PROFILE NEWLIST` is included automatically by the `REPORT PROFILE` command if the NEWLIST type was not yet specified in the input above the `REPORT` command.

Field descriptions

The `REPORT_PROFILE NEWLIST`

ACCESS

Repeat group field that returns the access level column of the annotated combined access list defined by ID, ACCESS, and WHEN.

AUDITF

Returns the lowest access level that results in auditing of access attempt failures. This value is empty if failure auditing is inactive.

The reported value for the access level is derived from the following settings:

- Profile settings (including the GLOBALAUDIT settings when you are an auditor).
- LOGOPTIONS settings for the class
- Any SECLEVEL or SECLABEL settings, if SECLEVEL or SECLABEL auditing is active.

This field does not support overtype, use AUDITLVL instead.

AUDITLVL

A combination field that returns the values from the AUDITS and AUDITF fields. However, this field can support overtype so that authorized users can change the value. This field is not available for selection. Use AUDITS and AUDITF instead.

AUDITS

Returns the lowest access level that results in success auditing. It is empty if success auditing is inactive.

The reported value for the access level is derived from the following settings:

- Profile settings (including the GLOBALAUDIT settings when you are an auditor).
- LOGOPTIONS settings for the class
- Any SECLEVEL or SECLABEL settings, if SECLEVEL or SECLABEL auditing is active.

This field does not support overtype, use AUDITLVL instead.

CLASS, C

Returns the RACF class name or entity type.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

ERASE

Flag field that shows whether erase-on-scratch is active for the profile. It only shows the profile flag. To be used, the corresponding SETROPTS and HSM settings must also be on. This field supports overtype.

ID

Repeat group field that the user or group ID column of the annotated combined access list defined by ID, ACCESS, and WHEN.

KEY

This field is part of a repeat group that includes the RACF profile name followed by the data set names that it covers. The data set names are only present when the REPORT DATASETS parameter has been requested.

ORDER

Returns a number that when sorted corresponds to the sort order designated by the REPORT BY= parameter. It can be used with the modifier NONDISPL to implement the REPORT BY= parameter.

PAGEBY

Returns a number that increases at each page break implied by the REPORT PAGEBY= parameter. It can be used with the modifiers PAGE,NONDISPL to implement the REPORT PAGEBY= parameter.

PROFTYPE

This field is part of a repeat group that includes the KEY, VOLUME, and the RACF profile type (GENERIC, NONVSAM, TAPE, MODEL) for the first or only line of an entry, and the data set type for subsequent lines. For a list of data set types see "PROFTYPE" on page 1244.

RESOURCE_LOCATION

Identifies the resource name environment. This field is part of a repeat group that includes the KEY, VOLSER, PROFTYPE, and SENSTYPE fields. The default and maximum length is 35 characters. An example value is IPO1.CICS.CICSTS41.DATASET. The format is as follows:

system.subsys-type.subsys-identification.restype

STAMP

Returns the unload time stamp of the RACF database. It cannot be used for SELECT/EXCLUDE processing.

UACC

Returns the universal access of the profile. This field supports overtype.

VOLSER

Repeat group field that includes the KEY value. In the report or display panel, the first or only line for an entry shows the volume serial of the RACF profile in the KEY field. This value is only provided for discrete profiles. In the subsequent lines, the volume serial is shown for the volume where the data sets in the corresponding line of the KEY are stored. The data set volume serial numbers are present only when the REPORT DATASETS option has been specified.

WHEN

Repeat group field that returns the conditional access column of the annotated combined access list defined by the ID, ACCESS, and WHEN fields. The WHEN value contains a class name and a profile name. For unconditional access list entries, this field is left blank.

REPORT_REDUNDANCY: RACF profile redundancy

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•		

The `REPORT_REDUNDANCY NEWLIST (NEWLIST TYPE=REPORT_REDUNDANCY)` reports if data set profiles can be considered redundant and if not, the *reason* why profiles were considered non-redundant.

For a profile to be considered *redundant*, three profile properties are checked:

1. Access requirements (access list, conditional access list, and universal access).
2. Audit requirements (failure audit level, success audit level).
3. Erase-on-scratch requirement.

The first two items are simply compared to those of the most specific matching generic profile, called the *candidate* profile. They must be equal before the profile is considered redundant. However, the *erase-on-scratch* requirement is not checked if the system wide option ERASE(ALL) or NOERASE is active.

The access requirement comparison is more complicated. Simplest is the *universal access* (UACC) comparison. For a profile to be considered redundant, its UACC must either be equal to that of the candidate profile, or less than ALTER and at the same time less than or equal to the most specific matching entry of the Global Access Table (for example, a member of the DATASET profile in class GLOBAL).

The *access list* and *conditional access list* comparison takes into account group membership of userids in the list. That is, a userid in the conditional list of a redundant profile might be missing from the conditional access list of the candidate profile only, if one of the connect groups is present with the same access (and the same program name), and no connect groups are present with a higher access (and the same program name).

Note that the redundancy check does not take all fields into account; e.g. the RESOWNER and NOTIFY fields, and security categories, levels, and labels are not checked.

The NEWLIST type was primarily designed to greatly automate conversions of all-discrete environments to generic.

Unless you include select statements, the NEWLIST can list some profiles twice: once as a candidate profile, and once as a non-redundant profile.

The CARLa scripts CKRREDUN and CKRRNONR containing this NEWLIST type are included automatically by the REPORT REDUNDANT and REPORT NONREDUNDANT commands if the NEWLIST type was not yet specified in the input above the REPORT command.

Field descriptions

The `REPORT_REDUNDANCY NEWLIST` supports the following fields for reporting.

`ACCESS`

Repeat group field that returns the access level column of the annotated combined access list defined by MARK, ID, ACCESS, and PROGRAM.

`AUDITF`

Returns the lowest access level that results in auditing of access attempt failures. It is empty if failure auditing is inactive.

The reported value for the access level is derived from the following settings:

- Profile settings (including the GLOBALAUDIT settings when you are an auditor).
- LOGOPTIONS settings for the class
- Any SECLEVEL or SECLABEL settings, if SECLEVEL or SECLABEL auditing is active.

This field does not support overtype, use AUDITLVL instead.

AUDITLVL

This field is a combination of the fields AUDITS and AUDITF ; contrary to these, it supports overtype . This field is not available for selection. Use AUDITS and AUDITF instead.

AUDITS

This returns the lowest access level that results in success auditing. It is empty if success auditing is inactive.

The reported value for the access level is derived from the following settings:

- Profile settings (including the GLOBALAUDIT settings when you are an auditor).
- LOGOPTIONS settings for the class
- Any SECLEVEL or SECLABEL settings, if SECLEVEL or SECLABEL auditing is active.

This field does not support overtype, use AUDITLVL instead.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

ERASE

Flag field that shows whether erase-on-scratch is active for the profile. It only shows the profile flag. To be used, the corresponding SETROPTS and HSM settings must also be on. This field supports overtype.

ID

Repeat group field returns the user or group ID column of the annotated combined access list defined by MARK, ID, ACCESS, and PROGRAM.

KEY

A repeat group field that returns the RACF profile name followed by the data set names that it covers. The data set names are only present when the REPORT DATASETS parameter has been requested.

MARK

Repeat group field that returns the annotation column of the combined access list defined by MARK, ID, ACCESS, and PROGRAM. The field contains an arrow '->' if the corresponding access list entry makes the profile non-redundant.

ORDER

Returns a number that when sorted corresponds to the sort order designated by the REPORT BY= parameter. It can be used with the modifier NONDISPL to implement the REPORT BY= parameter.

OWNER

Returns the owner of the RACF profile. This field supports overtype.

PAGEBY

Returns a number that increases at each page break implied by the REPORT PAGEBY= parameter. It can be used with the modifiers PAGE, NONDISPL to implement the REPORT PAGEBY= parameter.

PROFTYPE

This field is part of a repeat group with KEY and VOLSER. For the first or only line in the listing, it provides the RACF profile type (GENERIC, NONVSAM, TAPE, MODEL). For subsequent lines, it provides the data set type. For a list of data set types see "PROFTYPE" on page 1244.

PROGRAM

Repeat group field that returns the program conditional access column of the annotated combined access list defined by MARK, ID, ACCESS, and PROGRAM.

QUAL

Contains the data set qualifier as it can have been modified by the naming convention table ICHNCV00 and naming exit ICHCNX00.

REASON

This field helps to determine the reason why the profile is included in the report. In addition, the field MARK contains arrows to point to entries in the access list (or the OWNER field) that make the profile different from the most specific matching generic. While all access list entries are considered for marking with an arrow, the REASON field returns only the first condition that caused inclusion on the report. This condition does not necessarily result in an arrow in the MARK column, and neither does an arrow need to correspond with the first reason listed.

The reasons that can appear in the redundancy report are described in Table 415.

Table 415. REPORT_PROFILE REASON field: values and descriptions

Reason	Description
- candidate -	This is a generic profile or entry in the global access table that was the most specific matching generic for one of the profiles considered non-redundant.
- redundant -	This is only present if you requested REPORT REDUNDANT. It marks all profiles that were considered redundant.
Access	The access level of a user or group in the access list of this profile was different from the access level in the access list of the candidate profile for the same identity (user or group), and it was not overruled anyway by an entry in the global access table. The entry is one of the entries marked with an arrow.
Audit	The audit requirements are different from the candidate generic profile.
Erase	The erase-on-scratch requirement is different from that of the candidate generic profile. These profile requirements are not considered if the ERASE(ALL) or NOERASE global options are active.
Extra group	The access list of this profile contains a group that is not present on the access list of the candidate generic profile. It is one of the entries marked with an arrow.

Table 415. REPORT_PROFILE REASON field: values and descriptions (continued)

Reason	Description
Missing group	The access list of this profile does not contain a group that is present in the access list of the candidate generic profile. You must look up the candidate profile access list to see which group. No arrow is present.
Missing user	The access list of this profile does not contain a userid that is present in the access list of the candidate generic profile. Nor is that userid given the same access anyway by means of one of his connects. You must look up the candidate profile access list to see which group. No arrow is present.
No generic	There is no matching generic to serve as candidate.
Undefined id	There is an extra user or group present in the access list that is not present in the access list of the candidate generic profile. However, the user or group was not defined.
Used as model	The profile is used as a model on a USER or group profile and hence not redundant.
User no connect	Might also be called Extra User. A userid is present in the access list that is not present in the access list of the candidate profile. Nor does that user have a connect to any of the groups present in the access list of the candidate generic profile. The userid will be one of the entries marked by an arrow.
User privileged	A userid is present in the access list that is given more access than the equivalent entry in the access list of the candidate profile (either the userid or the connect group giving the highest access). The userid will be one of the entries marked by an arrow. You will have to look at the candidate profile access list to find the access level involved.
User restricted	A userid is present in the access list that is given less access than the equivalent entry in the access list of the candidate profile (either the userid or the connect group giving the highest access). The userid will be one of the entries marked by an arrow. You will have to look at the candidate profile access list to find the access level involved.
Universal access	UACC is different from the candidate profile's UACC.

STAMP

Returns the unload time stamp of the RACF database. It cannot be used for SELECT/EXCLUDE processing.

UACC

Returns the universal access of the profile. This field supports overtype.

VOLSER

Repeat group field that includes the KEY and PROFTYPE values. In the report or display panel, the first or only line for an entry shows the volume serial of the RACF profile in the KEY field. This value is only provided for discrete profiles. In the subsequent lines, the volume serial is shown for the volume where the data sets in the corresponding line of the KEY are stored. The data set volume serial numbers are present only when the REPORT DATASETS option has been specified.

REPORT_SCOPE: RACF profiles and data sets in scope

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
		•	•	•		

The REPORT_SCOPE NEWLIST (NEWLIST TYPE=REPORT_SCOPE) reports the scope of a user or group. This NEWLIST shows the profiles, and optionally, the resources to which a user or group has *direct* or *indirect* access. An example of indirect access is the ability to modify a profile to give oneself direct access. To generate the report, the NEWLIST TYPE=REPORT_SCOPE statement must be followed by a REPORT command. The REPORT command must include one or more SCOPE=*id* parameters that specify the users or groups to be included in the report. To prevent inadvertent listing of all or almost all profiles and resources in the system, the system-wide *special*, *operations*, and *auditor* attributes are *not* reported. The following access types are taken into account during the reporting process:

- Access permitted by universal access and warning mode of profiles.
- Access permitted by group ownership authority (special, operations, and auditor)
- Access permitted by CREATE authority through a connect or class authorization.
- Access through the Global access table.
- Access through missing profiles.
- Access through discrete/generic DATASET profiles mismatches (in a NOPROTECTALL environment).

Access through ownership, group-special, -operations, and -auditor authority is taken into account. as well as CREATE authority through a connect or class authorization

If the NEWLIST type was not yet specified in the input preceding the REPORT command, the REPORT SCOPE= command automatically includes the CARLa script CKRRSCOP that contains this NEWLIST type.

In the ISPF interface, the REPORT_SCOPE NEWLIST can be run from option **RA.3.4**.

Field descriptions

The REPORT_SCOPE NEWLIST provides the following fields for reporting.

ACCESS

Provides the access level the ID has to the resource listed in CLASS and KEY via the path specified through VIA and WHEN. If you want to support overtype for this field, use the ACCESS_VIA_WHEN field instead of ACCESS.

See "ACCESS= level" on page 876 for an explanation of ACCESS field values.

ACCESS_VIA_WHEN

This field is a combination of the ACCESS, VIA, and WHEN fields. However, the ACCESS_VIA_WHEN field can be modified (overtypeable), while the ACCESS and VIA fields cannot be modified. The ACCESS_VIA_WHEN field cannot be used in SELECT and EXCLUDE statements. To use this information for selection criteria, use the separate ACCESS, VIA, and WHEN fields.

CLASS, C

Returns the RACF class name or entity type.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

ID

Lists the user ID or group name that is used to determine the scope. This field must have been specified on a `REPORT SCOPE=`*id* command.

KEY

Repeat group that returns the RACF profile name followed by the data set names that it covers. The data set names are only present when the REPORT DATASETS parameter has been requested. See "REPORT" on page 875.

ORDER

Returns a number that when sorted corresponds to the sort order designated by the `REPORT BY=` parameter. It can be used with the modifier NONDISPL to implement the `REPORT BY=` parameter. See "REPORT" on page 875.

PAGEBY

Returns a number that increases at each page break implied by the `REPORT PAGEBY=` parameter. This value can be used with the modifiers `PAGE` and `NONDISPL` to implement the `REPORT PAGEBY=` parameter. See "REPORT" on page 875.

PROFTYPE

Part of a repeat group with the `KEY` and `VOLSER` fields. For the first or only line of an entry, this field returns the RACF profile type (*GENERIC*, *NONVSAM*, *TAPE*, *MODEL*) for the first or only line, and the data set type for subsequent lines. For a list of data set types see "PROFTYPE" on page 1244.

RESOURCE_LOCATION

Identifies the resource name environment. This field is part of a repeat group that includes the KEY, VOLSER, PROFTYPE, and SENSTYPE fields. The default and maximum length is 35 characters. An example value is IPO1.CICS.CICSTS41.DATASET. The format is as follows:

system.subsys-type.subsys-identification.restype

STAMP

Returns the unload time stamp of the RACF database. It cannot be used for `SELECT` and `EXCLUDE` processing.

VIA

Shows either a keyword in dashes or a user ID or group name that was instrumental in getting the access to the resource. For example, the value can be a connect group of the ID. If access was permitted through class authorization, the field value contains the user ID. To provide users with the ability to modify (overtype) this value, use the ACCESS_VIA_WHEN field instead of VIA.

Table 416. REPORT_SCOPE VIA field keywords and descriptions

Keyword	Description
-AUDIT-	Audit access permitted by the group=auditor attribute.
-CREATE-	Access permitted by connect authority of CREATE, JOIN or CONNECT. This access is even honored for revoked connects.
-CLAUTH-	Access permitted by user ID class authorization. Class authorization applies by POSIT number, and SETROPTS GENERICOWNER does not restrict adding profiles and members in a grouping class.
-GLOBAL-	Access permitted by the global access table.
-OPER-	Access permitted by the group-operations attribute.
-RACDCT-	Access permitted through an IRR.DIGTCERT.*function* resource in the FACILITY class.
-RACMAP-	Access permitted by the IRR.RACMAP.*function* resource in the FACILITY class.
-SCP.G-	Resource in scope due to access permitted on a CKG.SCP.G... scope check.
-SCP.ID-	Resource in scope due to access permitted on a CKG.SCP.ID... scope check.
-SCP.U-	Resource in scope due to access permitted on a CKG.SCP.U... scope check.
-UACC-	Access permitted through universal access.
-UNPROT-	Resource is not protected.
-WARN-	All access permitted due to warning mode.

VOLSER

Repeat group field that includes the KEY value. On the first or only line of an entry, this group field shows the volume serial for the RACF profile in the KEY field. This information is provided only for discrete profiles. In the subsequent lines, the volume serial is shown for the volume where the data sets in the corresponding line of the KEY are stored. The data set volume serial numbers are present only when the REPORT DATASETS option has been specified.

WHEN

Provides the class and profile name that must be in control for access to be permitted by RACF. To provide users with the ability to modify (overtype) this value, use the ACCESS_VIA_WHEN field instead of the VIA field.

REPORT_SENSITIVE: Sensitive data sets by profile

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	

The REPORT_SENSITIVE NEWLIST (NEWLIST TYPE=REPORT_SENSITIVE) has been designed to verify that sensitive data sets are adequately protected. Updates must be tightly controlled for some data sets like APF data sets, security databases, and page or swap data sets. For other data sets like the security database and page or swap data sets, read access to the information must be tightly controlled. zSecure Collect recognizes some sensitive data sets automatically. zSecure Admin and zSecure Audit verify RACF protection according to either *confidentiality* or *integrity* demands. The sensitive data sets checked automatically are:

- APF data sets (integrity)
- LPA data sets (integrity)
- Linklist data sets (integrity)
- Page data sets (confidentiality and integrity)
- System Storage Index data sets (confidentiality and integrity)
- Swap data sets (confidentiality and integrity)
- RACF data sets (confidentiality and integrity)
- SMF recording data sets (confidentiality and integrity)
- System dump data set (confidentiality and integrity)
- TSO user administration data set UADS (confidentiality and integrity)
- Other system data sets: SYS1.NUCLEUS and SYS1.LPALIB (integrity)
- JES2 and JES3 checkpoint data sets (confidentiality and integrity)
- JES2 and JES3 spool data sets (confidentiality and integrity)
- JES2 and JES3 parameter data set (confidentiality and integrity)
- JES2 and JES3 STC/TSU/JOB proclib (integrity, but only when SIMULATE SENSITIVE PROCLIB has been specified)
- JES2 spool offload data set (confidentiality and integrity)
- MSTR proclib (integrity)
- MSTR parameter library (integrity)
- MSTR VIO administration (integrity)
- DFHSM data set BCDS, MCDS, OCDS (integrity)
- DMS database DMSFILES (integrity)
- DMS authorized parameter library (integrity)
- DMS default parameter library (integrity)
- CA1 tape management catalog TMC (integrity)
- DFSMS SCDS and ACDS (integrity)
- IODF file, if DSN could be found (integrity)
- RMM control dataset and parmlib (integrity)
- TLMS volume master file VMF (integrity)
- ABR archive control file ACF (integrity)
- IPL load parameter data sets (integrity)
- HFS and zFS data sets (integrity)
- RRSF IN/OUT data sets (confidentiality and integrity)
- IEFJOBS data sets (integrity)
- Catalog data sets (ALTER)
- CS Resolver configuration files (integrity)

You can add your own data sets using the SIMULATE SENSITIVE command. See "SIMULATE" on page 911. LINKLIST data sets are automatically reported as APF

data sets, unless the IEASYSxx member in your system contains LNKAUTH=APFLST. If LINKLIST data sets are not automatically APF authorized, you can use the SIMULATE SENSITIVE LINKLIST command to report LINKLIST anyhow. SIMULATE SENSITIVE PROCLIB can be used to flag integrity problems in the JES2 proclibs used for batchjobs.

The security policy adhered to conforms to the DOD 5200.28-STD standard ('Orange Book') at C2 level or to the Common Criteria V1.0 profile CS1.

The security policy adhered to for *confidential* data sets is:

1. Confidential data sets must be protected against READ access.
2. READ access must be audited.
3. Information must be erased physically when deleted.

The security policy adhered to for *integrity-sensitive* data sets is:

1. Integrity-sensitive data sets must be protected against UPDATE.
2. UPDATE access must be audited.

For the check on audit trail on RACF systems, both AUDIT and GLOBALAUDIT settingsare checked. GLOBALAUDIT is not checked in PADS mode if you don't have the AUDITOR attribute. In addition, the LOGOPTIONS setting is considered as well as SECLEVELAUDIT and SECLABELAUDIT settings when SECLEVELs or SECLABELs are active. The check is passed if any of these settings provides the required level of auditing.

The REPORT_SENSITIVE NEWLIST returns a record for each sensitive data set found, grouped by the covering data set profile.

The CARLa script CKRRSENS containing this NEWLIST type is included automatically by the REPORT SENSITIVE command if the NEWLIST type was not yet specified in the command input preceding the REPORT command.

Field descriptions

The REPORT_SENSITIVE NEWLIST provides the following fields for reporting.

ACCESS

This repeat group field returns the access level column of the annotated combined access list defined by MARK, ID, ACCESS, and PROGRAM.

AUDITCONCERN,CONCERN

This field returns a concatenation of audit concerns for the profile. Table 417 shows the default audit priority and concerns. The priority can be higher due to a SIMULATE POLICY statement.

Table 417. REPORT_SENSITIVE: AUDITCONCERN priorities and descriptions

Priority	Audit Concern	Description
60	Unprotected	There is no profile protecting the data set, and PROTECTALL(FAILURES) is not set
55	Global access	The access given through the Global Access Table is too high
50	UACC too high	Universal access should be NONE or READ
45	ID(*) too high	ID(*) on the access list has too high access
45	Warning mode access	Warning mode on profile resulted in ALTER access

Table 417. REPORT_SENSITIVE: AUDITCONCERN priorities and descriptions (continued)

Priority	Audit Concern	Description
35	No erase	Erase on scratch required for confidentiality
15	Read fail audit	Read failure audit required for confidentiality
15	Update fail audit	Update failure audit required for integrity
15	Alter fail audit	Alter failure audit required for integrity
10	No read audit	Read audit required for confidentiality
10	No update audit	Update audit required for integrity
10	No alter audit	Alter audit required for integrity

The command VERIFY SENSITIVE can be used to generate RACF commands that remedy profile deficiencies.

AUDITF

This returns the lowest access level that results in auditing of access attempt failures. It is empty if failure auditing is inactive.

The reported value for the access level is derived from the following settings:

- Profile settings (including the GLOBALAUDIT settings when you are an auditor).
- LOGOPTIONS settings for the class
- Any SECLEVEL or SECLABEL settings, if SECLEVEL or SECLABEL auditing is active.

This field does not support overtype, use AUDITLVL instead.

AUDITLVL

This field is a combination of the fields AUDITS and AUDITF ; contrary to these, it supports overtype . This field is not available for selection. Use AUDITS and AUDITF instead.

This field returns the audit priority for the profile. See field AUDITCONCERN for a table with the concerns and their priorities. The actual audit priority can be higher because of e.g. a SIMULATE POLICY C2 statement.

AUDITS

This returns the lowest access level that results in success auditing. It is empty if success auditing is inactive.

The reported value for the access level is derived from the following settings:

- Profile settings (including the GLOBALAUDIT settings when you are an auditor).
- LOGOPTIONS settings for the class
- Any SECLEVEL or SECLABEL settings, if SECLEVEL or SECLABEL auditing is active.

This field does not support overtype, use AUDITLVL instead.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

ERASE

This flag field shows whether erase-on-scratch is active for the profile. It only shows the profile flag. To be used, the corresponding SETROPTS and HSM settings must also be on. This field supports overtype.

ID

This repeat group field returns the user or group ID column of the annotated combined access list defined by MARK, ID, ACCESS, and PROGRAM.

KEY

For RACF, this repeat group field returns the profile name covering the sensitive data sets on the first line. On subsequent lines, the (sensitive) data sets it covers are listed. It is part of the same repeat group as PROFTYPE, SENSTYPE and VOLSER. If the REPORT DATASETS option has been added (specify behind your NEWLIST requests), then all non-sensitive data sets covered will be included as well.

MARK

This repeat group field returns the annotation column of the combined access list defined by MARK, ID, ACCESS, and PROGRAM The field contains an arrow '->' to highlight a specific access list entry that has a problem.

ORDER

This field returns a number that when sorted corresponds to the sort order designated by the REPORT BY= parameter. It can be used with the modifier NONDISPL to implement the REPORT BY= parameter.

OWNER

This field returns the owner of the RACF profile. This field supports overtype.

PAGEBY

This field returns a number that increases at each page break implied by the REPORT PAGEBY= parameter. It can be used with the modifiers PAGE,NONDISPL to implement the REPORT PAGEBY= parameter.

PROFTYPE

This repeat group field returns RACF profile the type of (missing, GENERIC, NONVSAM, TAPE or MODEL) on the first line, and the type of data set for a data set repeat group entry (nvsam, clust, tape, etc.) on subsequent lines. It is part of the same repeat group as KEY, PROFTYPE, SENSTYPE and VOLSER. Table 418 shows the data set types and their meaning.

Table 418. REPORT_SENSITIVE: PROFTYPE dataset types and descriptions

bkpclu	Backup of a VSAM cluster. Normally, this is only listed below a backed-up discrete profile (for example, a discrete profile with a system-generated name). The source for the cluster name is the HSM BCDS or a DMS DMSFILES data set.
clustr	VSAM cluster (catalog entry). The volume listed is the volume of the catalog. The source for the cluster names can be a catalog, HSM MCDS, ABR ACF, DMS DMSFILES data set, or VVDS.

	index	Index component of a VSAM cluster residing on the indicated DASD volume.
	data	Data component of a VSAM cluster residing on the indicated DASD volume.
	aixix	Index component of a VSAM alternate index residing on the indicated DASD volume.
	aixda	Data component of a VSAM alternate index residing on the indicated DASD volume.
	migcl	Migrated or archived VSAM cluster. This is listed below a cluster entry instead of the components. The volume is equal to MIGRAT or ARCIVE.
	clust	Backup of VSAM cluster. This is listed below a bkpclu entry instead of the components. The volume is equal to MIGRAT or ARCIVE.

cmmtap	Cataloged, managed tape file on a managed, non-scratch tape volume.
cnmtap	Cataloged, non-managed file on a managed, non-scratch volume. This means that the catalog entry conflicts with the tape management information.
cnntap	Cataloged, non-managed tape file, on a non-managed volume.
cnstap	Cataloged, non-managed file, on a managed volume in scratch status.
gdg	Base name of a GDG (Generation Data Group), obtained from a catalog.
mdisk	VM minidisk. The minidisk resource name has the form USERID.DEVN or ACIGRP.USER.DEVN
notfnd	Data set name is in some table but the data set itself does not exist.
nvsam	Non-VSAM disk data set, migrated if volume is MIGRAT (for HSM or ABR) or archived if the volume is ARCIVE (for DMS). This information is obtained from the VTOC for data sets on disk, the HSM MCDS and the ABR ACF for migrated data sets, and the DMSFILES data set for archived data sets. The information is not derived from the catalog entries.
priv	General resource name where even access less than READ is a sensitive privilege.
secvol	Secondary volume of a multi-volume data set.
sens-a	General resource name where ALTER access is sensitive.
sens-r	General resource name where READ access is sensitive.
sens-w	General resource name where WRITE access is sensitive.
ummtap	Uncataloged, managed tape file on a managed, non-scratch tape volume.
unmtap	Uncataloged, non-managed file on a managed, non-scratch volume. The source for such an entry is probably the TVTOC of a TAPEVOL profile.
unntap	Uncataloged, non-managed tape file, on a non-managed volume. The source for such an entry is probably the TVTOC of a TAPEVOL profile.
unstap	Uncataloged, non-managed file, on a managed volume in scratch status. The source for such an entry is probably the TVTOC of a TAPEVOL profile.

PROGRAM

This repeat group field returns the program conditional access column of the annotated combined access list defined by MARK, ID, ACCESS, and PROGRAM.

RESOURCE_LOCATION

Identifies the resource name environment. This field is part of a repeat group that includes the KEY, VOLSER, PROFTYPE, and SENSTYPE fields. The default and maximum length is 35 characters. An example value is IPO1.CICS.CICSTS41.DATASET. The format is as follows:

system.subsys-type.subsys-identification.restype

PROGRAM

This repeat group field returns the program conditional access column of the annotated combined access list defined by MARK, ID, ACCESS, and PROGRAM.

SENSTYPE

This repeat group field denotes the type of sensitivity of an individual data set. It is part of the same repeat group as KEY, PROFTYPE, SENSTYPE, and VOLSER.

In case of multiple sensitivities for a single data set, only the prime sensitivity or sensitivities are represented. For instance, a data set can be a MSTR parmlib, a JES2 parmlib, an STC proclib and a JOB proclib all at the same time. In this case, JES2 parmlib will win because that data set might contain human readable passwords.

STAMP

This field returns the time stamp of the security database. It cannot be used for SELECT/EXCLUDE processing.

UACC

For a RACF system, this field returns the combined universal access of the profile UACC, the global access table, and the protectall setting (in case the profile is missing). This field supports overtype.

VOLSER

This field is a repeat group with KEY PROFTYPE, SENSTYPE, and VOLSER. On the first line it shows the volume serial of the RACF profile in the KEY field (only filled in if it is a discrete). On the following lines the volume serial where the data sets in the corresponding line of KEY reside is shown.

REPORT_STC: Started procedure protection

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	

The `REPORT_STC NEWLIST` (`NEWLIST TYPE=REPORT_STC`) helps determine which started procedures pose a risk to the installation. This `NEWLIST` returns a record for each JCL member that can be started with the `START` command.

The CARLa script CKRRSTC containing this `NEWLIST` type is included automatically by the `REPORT STC` command if the NEWLIST type was not yet specified in the input above the `REPORT` command.

The consistency of the three information sources (ICHRIN03, RACF database, and procedure libraries) can be verified by running the VERIFY STC command.

Field descriptions

The REPORT_STC NEWLIST provides the following fields for reporting.

AUDITOR

Flag field that indicates in a RACF system that the started procedure will run with a RACF userid that has system-wide AUDITOR authority.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

CONCAT

This field is part of a repeat group together with the field SUBSYS It lists the sequence number of the procedure library listed by DSN in the concatenation. Each subsystem on each system can have its own concatenation. See also HIDDEN

DSN

The field lists the data set name of the started procedure library where the JCL member resides.

FLAGS

This is a text field that contains special authorizations or conditions for the started task. This information comes from the RACF user profile and connect definition, from the Start Procedure Table ICHRIN03 entry, or from the RACF STARTED profile. A letter can be displayed at a specific column. Table 419 describes the possible values for this field..

Table 419. REPORT_STC Flags field - Available values

Flag	Description
*	An unusual condition exists for this task, a database or table mismatch for example. The reason might be found by running VERIFY STC.
r	The user assigned to the started procedure is revoked. Depending on your RACF and PTF level, the task cannot be started because it is revoked, or the task will run with reduced functionality. It might have problems submitting batch jobs, allocating new SMS-managed data sets, or obtaining printed output.
s	System-wide SPECIAL authority.
o	System-wide OPERATIONS authority.

Table 419. REPORT_STC Flags field - Available values (continued)

Flag	Description
a	System-wide AUDITOR authority.
p	The task is privileged. This means that all access requests (except those that request a profile to be returned in-storage through the use of the CSA or PRIVATE keywords) are granted and auditing is suppressed.
t	The task is trusted. This means that all access requests (except those that request a profile to be returned in-storage through the use of the CSA or PRIVATE keywords) are granted and only limited auditing possibilities exist. Auditing is only possible via SETROPTS LOGOPTIONS and the UAUDIT setting for the userid.
D	The group specified in the Started Procedures Table or the STARTED profile is the default group for the user. [12]
S	The procedure uses a RACF STARTED profile.
3	The procedure uses ICHRIN03.

GROUP

The current connect group that is used if the task is started.

GROUP_DFLTGRP

For a RACF system, this flag field indicates that the started task runs under the default group for the RACF user.

HIDDEN

Flag field that indicates that the procedure JCL is hidden from view in the STC proclib concatenation. This can happen if there is a similarly named member in a procedure library concatenated in front of this library.

ICHRIN03

Flag field that indicates in a RACF system that the procedure name is part of the started task table ICHRIN03.

ISPF_DATE

The last modification date in the ISPF statistics of the JCL member. This has only documentary value and no security relevance since it can be changed at will by the updater. For detailed instructions on how to use this field in SELECT/EXCLUDE specifications, see “Date fields” on page 903.

ISPF_USERID

This is the userid present in the ISPF statistics of the JCL member. This has only documentary value and no security relevance since it can be changed at will by the updater.

LAST_CHANGE

This field indicates the date and time when the JCL member was last changed or when it was created, whichever is more recent. If the current JCL member version belongs to a PDSE data set and has extended member statistics, this

12. Job submission from started tasks used to be protected by assuring that the started task RACF user default group was a RACF group specifically for started tasks, and making sure that the connect to this group was revoked. This construction made sure that no job could be submitted without a password. Since the class PROPCNTL has been introduced this mechanism can be replaced by a profile for the started task in that class. In addition, it is now customary to allow submission with a GROUP= parameter on the JOB card without specifying a password, so the old protection mechanism does not really work anymore.

field provides the extended member statistics. Otherwise, this field provides ISPF statistics information for the member which includes the ISPF_DATE. For information on using this field in SELECT and EXCLUDE statements, see "Combined date and time fields" on page 904.

LAST_CHANGE_USERID

This field indicates the user ID that was last used to modify the JCL member. If the current JCL member version belongs to a PDSE data set and has extended member statistics, this field provides the user ID taken from the extended member statistics. Otherwise, this field provides the user ID taken from the ISPF statistics for the member. (See "ISPF_USERID" on page 1248.)

OPERATIONS

Flag field that indicates in a RACF system that the started procedure will run with a RACF userid that has system-wide OPERATIONS authority.

ORDER

This field returns a number that when sorted corresponds to the sort order designated by the REPORT BY= parameter. It can be used with the modifier NONDISPL to implement the REPORT BY= parameter.

PAGEBY

This field returns a number that increases at each page break implied by the REPORT PAGEBY= parameter. It can be used with the modifiers PAGE,NONDISPL to implement the REPORT PAGEBY= parameter.

PRIVILEGED

Flag field that indicates in a RACF system that the started procedure runs with the privileged attribute. All access requests (except those that request a profile to be returned in-storage through the use of the `CSA` or `PRIVATE` keywords) are granted and auditing is suppressed. If the `PRIVILEGED` flag is set, RACF ignores the value of the `TRUSTED` setting. Accordingly, the `REPORT_STC NEWLIST` reports the `TRUSTED` flag as not set.

PROCNAME

The name of the procedure JCL member in the procedure library. This name is used on the START command to start the task.

PROFILE

The RACF STARTED profile, if one is found.

PROTECTED

This flag field indicates whether the user ID associated with the started task is protected or not. A protected user ID does not have a password and cannot be revoked by entering incorrect passwords.

SPECIAL

Flag field that indicates in a RACF system that the started procedure will run with a RACF userid that has system-wide SPECIAL authority.

STAMP

This field returns the unload time stamp of the security database. It cannot be used for SELECT/EXCLUDE processing.

SUBSYS

This field is the key of a repeat group with the field CONCAT. It lists the subsystem name the output line applies to. The START command can be issued with this subsystem name in the SUB= parameter. The SUB= parameter is required to direct the START command to a subsystem other than the default (primary) subsystem.

SYSTEM

This is the SMF id of the system NEWLIST record applies to. Note that each system can have its own Started Procedure Table ICHRIN03, even while sharing the RACF database.

TRUSTED

For a RACF system, this flag field indicates that the started procedure runs with the trusted attribute. All access requests (except those that request a profile to be returned in-storage through the use of the CSA or PRIVATE keywords) are granted and only limited auditing possibilities exist. Auditing is only possible via SETROPTS LOGOPTIONS and the UAUDIT setting for the userid. If the PRIVILEGED flag is set, RACF ignores the value of the TRUSTED setting. Accordingly, the REPORT_STC NEWLIST reports the TRUSTED flag as not set.

UACC

This field returns the universal access of the JCL member. If this is UPDATE, and the started task has system level authorities, then a major leak exists. If it is UPDATE and the userid has no system level authorities, a trojan horse risk exists. If it is READ then this is of value to hackers if they have found a way to issue a START command. This field is only present for RACF systems.

USERID

This field lists the userid assigned by the RACF Started Procedure Table ICHRIN03, or by a STARTED profile. This field can contain *, this is the default RACF user for a task originating from within the system. If you want to suppress these report lines, specify SUPPRESS ID=*. For an invalid STARTED profile, this column can contain ++++++++, which is the 'undefined' user.

VOLSER

This field lists the volume serial where the procedure library listed by field DSN resides.

ROUTER: SAF Router Table

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•		

The ROUTER NEWLIST (NEWLIST TYPE=ROUTER) displays the SAF (System Authorization Facility) router table. It generates one entry per entry in the table. A unique key is SYSTEM ORDER.. Unless otherwise noted, you can use all fields for SELECT and EXCLUDE processing as well as in the following output commands: LIST, SORTLIST, SUMMARY, and DISPLAY.

Field descriptions

The ROUTER NEWLIST provides the following fields for reporting.

ACTION

This string indicates the action to be taken for this requestor, class, and subsystem. It has the value 'NONE' when RACROUTE requests are to be ignored (RC=0), and 'RACF' when RACF is to be called, for example, a value of 'NONE' indicates that authorization requests by the indicated requestor and subsystem for the indicated class is allowed without checking any profiles.

AUDITCONCERN, CONCERN

This field indicates the reason for the audit priority. You should not use the exact value of this field as a programming interface. The audit concern currently defined is:

- Class not in CDT

  This means that SAF (System Authorization Facility) cannot pass a security check in this class to RACF, because RACF does not know it. If the router table indicates it is passed to RACF, this is given priority 15; if not, 3.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 420. ROUTER NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

CLASS, C

The class name passed to the RACROUTE call.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. The complex name can come from the ALLOC COMPLEX parameter or default to a system name.

INCDT

This flag indicates whether the current class is included in the Class Descriptor Table (CDT, see NEWLIST TYPE=CLASS). Normally, the only non-general resource classes that can have INCDT=NO are DATASET, USER, CONNECT, and GROUP.

ORDER, ORG

The original order (entry number) of this class entry in the RACF router table. The first entry in the table has ORDER=1.

REQSTOR

The requestor name passed to the RACROUTE call.

SUBSYS

The subsystem name passed to the RACROUTE call.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. The field length is 8 characters to cater to VM systems.

RRNG: RACF Database Range Table

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•		

The RRNG NEWLIST (NEWLIST TYPE=RRNG) describes the RACF Database Range Table. This table determines which RACF profiles are stored in which RACF data set. This NEWLIST generates one entry per key range per system. A unique key is SYSTEM ORDER. It displays the in-storage range table loaded from module ICHRRNG during IPL. Unless otherwise noted, you can use all RRNG NEWLIST fields for SELECT and EXCLUDE processing as well as in the following output commands: LIST, SORTLIST, SUMMARY, and DISPLAY.

Field descriptions

The RRNG NEWLIST provides the following fields for reporting.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. The complex name can come from the ALLOC COMPLEX parameter or default to a system name.

DB

RACF data set sequence number. This number identifies the data set in the Database Name Table (DSNT) that must be used for this key range. Information on these data sets can be displayed with a NEWLIST TYPE=DSNT.

KEY

Lowest profile key for this data set. Profiles with keys higher than or equal to this key (and lower than the next lowest key in the table) are routed to the data set with a sequence number DB (value of the DB parameter). Unreadable characters are *not* replaced by a period.

KEYHEX

Lowest profile key for this database, in hexadecimal format. Profiles with keys higher than or equal to this key (and lower than the next lowest key in the table) are routed to the data set with sequence number DB.

ORDER, ORG

The original order (entry number) of this entry in the resource range table. The first entry in the table has ORDER=1.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. The field length is 8 characters to cater to VM systems.

RRSFNODE: RRSF configuration information

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•	•			•	•	•

The RRSFNODE NEWLIST (NEWLIST TYPE=RRSFNODE) returns the RRSF node information for the current system configuration. The information is obtained from existing CKFREEZE files. This NEWLIST type supports processing multiple CKFREEZE files to provide a multinode view of the entire configuration.

Note: For information about NEWLIST statements, processing, and formatting options, see "NEWLIST" on page 846.

Field descriptions

The RRSFNODE NEWLIST provides the following fields for reporting.

ADDRESS
The host name or IP address entered on the TARGET command when defining an RRSF node with TCP protocol.

APPC_LUNAME
Logical Unit name for RRSF connection to the TARGET_NODE if the APPC communication protocol is APPC.

APPC_MODENAME
SNA mode name designating the network properties to be used when setting the APPC connection to the TARGET_NODE.

APPC_TPNAME
The APPC Transaction Profile Name (TPNAME). The value returned can have between one and 64 characters.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX
Name of the security complex that contains the system where the RRSF node is defined. The value returned can be from the ALLOC COMPLEX parameter or default to a system name.

DESCRIPTION
The user-specified description for this RRSF node.

IS_LOCAL
Flag field (Yes/No) that indicates whether this node is designated as the local node for SYSTEM.

IS_MAIN
This Flag field (Yes/No) that indicates if this system is the main system in the RRSF node.

LOCAL_NODE
The name of the local RRSF node for this system.

PORTNUM
The port number entered on the TARGET command when defining an RRSF node with TCP protocol.

PROTOCOL
Protocol for communication. The value can be APPC (Advanced Program-to-Program Communications) or TCPIP for (Transmission Control Protocol/Internet Protocol).

SYSTEM
Name of the system where the RRSF node is defined.

TARGET_NODE
The name of the remote RRSF node.

TARGET_SYSNAME
The (GRS) name of the remote system. The target node is local to this system.

TARGET_SYSTEM
The (SMF) name of the remote system. The target node is local to this system.

TARGET_COMPLEX
The target system is a member of this complex.

TARGET_STATE
The state of the remote RRSF node. Table 421 lists the possible state values.

Table 421. RRSF node state values

Value	Description
O_A	Operative Active
O_P_C	Operative Pending Connect
O_P_V	Operative Pending Verify
O_E	Operative Error
D_L	Dormant Local
D_R	Dormant Remote
D_B	Dormant Both
D_E	Dormant Error
???	Unknown state

USERID
The ID of the user that created this RRSF node definition.

WORKSPACE_PREFIX
The high-level qualifiers for the workspace data set. This value is specified by the PREFIX keyword on the TARGET command. The format for the prefix value is different for local and remote data sets. For a local workspace data set, the prefix is specified as `prefix .sysname | wdsqual .INMSG | OUTMSG`. For data sets available through a remote connection, the prefix is formatted as `prefix . local_luname . remote_luname | wdsqual . INMSG | OUTMSG`.

WORKSPACE_QUALIFIER
The middle qualifier for the workspace data set name. This value is specified by the WDSQUAL keyword on the TARGET command.

WORKSPACE_VOLUME
The volume serial number for the workspace data set if configured.

WORKSPACE_FILESIZE
The file size for the DEFINE CLUSTER of a VSAM workspace data set. This value represents the maximum number of entries that the data set can hold.

WORKSPACE_DATACLAS
The SMS DATACLAS for the workspace data set.

WORKSPACE_STORCLAS
The SMS STORCLAS for the workspace data set.

WORKSPACE_MGMTCLAS
The SMS MGMTCLAS for the workspace data set.

SENSDSN: Sensitive Data Set Names

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•	•			•	•	•

The SENSDSN NEWLIST (NEWLIST TYPE=SENSDSN) describes the sensitive data set names, taken from the in storage APFLIST, LINKLIST, and LPALIST tables, and from common and private system and subsystem control blocks. Each entry in this NEWLIST represents one sensitive data set, and is uniquely identified by the fields SYSTEM DATASET VOLSER.

A SENSDSN NEWLIST (NEWLIST TYPE=SENSDSN) comparison report can show a change for a sensitive data set that is accessible from only one of the systems being compared. This occurs because a sensitive data set from any of the input CKFREEZE files is considered as sensitive on the other systems as well. However, when a sensitive data set resides on a non-shared DASD, it is treated as not mounted on some systems and mounted on other systems. A CKFREEZE file for each system does not provide any information about the DSN and volume inventory on any other system. When multiple CKFREEZE files are input to the comparison, the volsers and data sets are treated as if they were potentially sensitive in every system. This design provides a report that shows a consolidated overview of all the sensitive data sets and their status in the entire combined environment. Consequently, a sensitive data set is considered sensitive everywhere, even if the data set was not accessible from a system when the CKFREEZE file was created.

Field descriptions

The SENSDSN NEWLIST provides the following fields for reporting.

APF

This flag field indicates whether the data set is APF-authorized. The data set is part of the APFlist, the linklist if it is authorized, or the LPAlist.

Note: A data set can be part of the APFlist and not be APF-authorized. In that case, the APF flag is not set, and the APFLIST flag is set. The following reasons for this exist:

- The data set named in the APF list does not have a volume serial, but is cataloged to a non-SMS-managed volume.
- The data set named in the APF list is an alias.
- The data set named in the APF list has a volume serial, but no such data set exists.

- The data set named in the APF list has a volume serial, but the volume is not mounted.
- The data set named in the APF list does not have a volume serial, but is not cataloged.

In this, Security zSecure follows the MVS rules.

APFLIST

This flag field indicates whether the data set is part of the APFlist, or part of the linklist if it is authorized.

AUDITCONCERN, CONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field. The AUDITCONCERN field can contain one or more concerns separated by commas. The following audit concerns have currently been defined:

In APFlist but no volser and not cataloged to SMS-managed volume

The data set is in the APFlist without volume serial, but the data set is cataloged to a non-SMS-managed volume. The data set is not APF-authorized.

In APFlist but an alias

The data set is in the APFlist but is an alias. The data set is not APF-authorized.

In APFlist but data set not on volume
The data set is in the APFlist with volume serial, however no such data set exists.

In APFlist but volume not mounted

The data set is in the APFlist with volume serial, but the volume is not mounted. The data set is not APF-authorized.

In APFlist but data set not cataloged

The data set is in the APFlist without volume serial but the data set is not cataloged. The data set is not APF-authorized.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 422. SENSDSN NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

BOX_SERIAL

This field describes the DASD unit's volume serial number and device id for the data set. This field can be used to disambiguate between DASD volumes with the same VOLSER. See also “BOX_SERIAL field for DASDVOL report” on page 1014.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. The complex name can come from the ALLOC COMPLEX parameter or default to a system name.

DATASET, DSN

This field contains the data set name. When combined with the SYSTEM and VOLUME fields, this field uniquely identifies an entry in the NEWLIST TYPE=SENSDSN.

ERASE

This field is empty in Security zSecure.

LINKLIST

This field indicates the linklist concatenation number of the data set, if it is part of the linklist.

LNKAUTH

This flag field indicates whether the data set is in the linklist and the linklist is considered APF-authorized (because of a LNKAUTH=LNKLIST in the effective IEASYSxx parmlib member).

LPALIST

This flag field indicates the LPAlist concatenation number of the data set, if it is part of the LPAlist.

MOUNTED

This flag field indicates whether the data set volume is mounted. In this release, this flag is only valid if the DASDVOL report is also used.

RESOURCE_LOCATION

Identifies the resource name environment. This field is repeat group field. The default and maximum length is 35 characters. An example value is IPO1.CICS.CICSTS41.DATASET. The format is as follows:

system.subsys-type.subsys-identification.restype

RISK

This field indicates the lowest access level considered an exposure, which is dependent on the data set sensitivity type. Possible RISK values are READ, UPDATE, and ALTER.

Data set types with a READ risk

ACF2 databases, alternate clusters and backup databases

ICSF key data sets CKDS, PKDS, and TKDS

JES2 parameter, checkpoint, spool and spool offload data sets

RRSF IN/OUT data sets
SMF recording data sets
System dump, page, and swap data sets
UADS data set

Data set types with an UPDATE risk

Aliases in the APFlist
ABR archive control file (ACF)
ACF2/CICS parameter library (CICS ACF2pr)
ACF2 MAINT, BLPPGM and LINKLST record libraries
APF list data sets
CA1 tape management catalog (TMC)
CICS program library (CICS Loadlb).
CICS resource definition data set (CICS CSD)
CICS parameter library (CICS Parms)
Communications Server configuration and include files
Couple data sets (Primary and Alternate)
CS Resolver configuration files
DB2 Bootstrap data set (BSDS)
DMS database and parameter libraries
HSM MCDS, OCDS, and BCDS data sets
HFS and zFS data sets
IMS program library (IMS PROCLIB)
IPL nucleus data set
IPL parameter libraries
JES2 and JES3 STC/TSU/JOB proclibs
LPA list data sets
Linklist data sets
RMM parameter library and control data sets
SMS ACDS, COMMDS, and SCDS data sets
Storage index data set
System active IODF data set
System IEFJOBS data sets
System parameter library
System REXX library
TLMS volume master file (VMF)
UNIX zFS file system in a VSAM linear data set (zFS data set)

Data set types with an ALTER risk

Catalogs
Data sets in the APF list with a volume serial that does not exist
Data sets in the APF list with a volume serial that is not mounted
Data sets in the APF list without a volume serial that are cataloged to a non-SMS-managed volume
Data sets in the APF list without a volume serial that are not cataloged

SENSITIVITY

This field indicates the type of sensitivity of the data set. The following sensitivity types have been defined:

Table 423. SENSDSN: Sensitivity types and descriptions

Sensitivity	Meaning
ABR ACF	ABR Archive Control File (ACF)
Active IODF	System active IODF data set
APF library	APF library, not in linklist or LPAlist
APF lib+Lnk	Library in APFlist and linklist, not in LPAlist
APF linklst	Library in linklist (authorized), not in APF list, nor in LPA list
APF LPA+Lnk	Library in APF list, LPA list and linklist
APF LPAlist	Library in APF list and LPA list, not in linklist
CA1 TMC	CA1 Tape Management Catalog (TMC)
Catalog	Catalog data sets
CICS Loadlb	CICS program library
CICS CSD	CICS resource definition data set
CICS Parms	CICS parameter library
CICS ACF2pr	ACF2/CICS parameter library
Couple Alt	Alternate couple data set
Couple Prim	Primary couple data set
CSconfig	Default library found in the standard Communications Server configuration file search sequence
CSinclude	Communications Server include file
DB2 BootSDS	DB2 Bootstrap data set (BSDS)
DftTCPIPDta	CS Resolver default TCPIP.DATA file
DftIPNODES	CS Resolver default IPNODES file
DMS AuthPrm	DMS authorized parameter library
DMS parmlib	DMS default parameter library
DmsFiles	DMS DMSFILES database
HFS data set	HFS
GlbTCPIPDta	CS Resolver default TCPIP.DATA file
GlbIPNODES	CS Resolver global IPNODES file
HSM BCDS	HSM BCDS data set
HSM MCDS	HSM MCDS data set
HSM OCDS	HSM OCDS data set
ICSF CKDS	Cryptographic Key data set with encrypted symmetric keys
ICSF PKDS	Cryptographic Key data set with encrypted asymmetric (public/private) key
ICSF TKDS	Data set with cryptographic tokens (encrypted or clear)
IMS PROCLIB	IMS program library.
IPL LoadPrm	Library in logical parmlib concatenation used at IPL
IPL nucleus	z/OS nucleus data set, executable code loaded at IPL time
JES2 Ckpt	JES2 checkpoint data set

Table 423. SENSDSN: Sensitivity types and descriptions (continued)

Sensitivity	Meaning
JES2 prmlib	JES2 parameter library
JES2 Spool	JES2 spool data set
JES3 Ckpt	JES3 checkpoint data set
JES3 prmlib	JES3 parameter library
JES3 Spool	JES3 spool data set
JOB proclib	JES2 or JES3 JOB proclib (this sensitivity type is only shown when SIMULATE SENSITIVE PROCLIB has been specified)
Linklist	Linklist library (not authorized), not in APF list, nor in LPA list
LPA+APF Lnk	Library in LPAlist and linklist (authorized), not in APF list.
LPA+Linklst	Library in LPA list and linklist (not authorized), not in APF list
LPAlist	LPA list library, not in APF list, nor in linklist
MSTR prmlib	Master parameter library
MSTR STClib	Master Started Procedure library
NoAPF alias	Alias in the APFlist
NoAPFnonSMS	Library in the APFlist without a volser, but cataloged to a non-SMS-managed volume
NoAPFnoCtlg	Library in the APF list without a volume serial, but not cataloged
NoAPFnotMnt	Library in the APF list with a volume serial, but the volume is not mounted
NoAPFnoDsn	Library in the APF list with a volume serial, but the data set does not exist
Offload	JES2 spool offload data set
Pagedataset	System page data set
RACF back	RACF backup database
RACF prim	RACF primary database
ResolvSetup	CS Resolver setup file
RMM Control	RMM control data set
RMM parmlib	RMM parameter library
RRSFdataset	RRSF IN/OUT data set
Sens Read	READ sensitive on another system, but also available on this system
Sens Update	UPDATE sensitive on another system, but also available on this system
SMF dataset	SMF recording data set
SMS ACDS	SMS ACDS data set
SMS COMMDS	SMS COMMDS data set
SMS SCDS	SMS SCDS data set
STC joblib	System IEFJOBS data set
STC proclib	JES2 or JES3 STC proclib
StgIndex	System Storage Index data set
Swapdataset	System swap data set
System Dump	System dump data set

Table 423. SENSDSN: Sensitivity types and descriptions (continued)

Sensitivity	Meaning
System REXX	Library with REXX programs that execute APF authorized
TLMS VMF	TLMS Volume Master File (VMF)
TSO UADS	UADS data set
TSU proclib	JES2 or JES3 TSU proclib
zFS data set	UNIX zFS file system (in a VSAM linear data set)

In case there are multiple sensitivities for a single data set, only the prime sensitivity or sensitivities are represented. For instance, a data set can be a MSTR parmlib, a JES2 parmlib, an STC proclib and a JOB proclib all at the same time. In this case it will be shown as a JES2 parmlib, because that data set can contain human readable passwords.

Note that for data sets on the LPA list and linklist the APF flag might be set. This is because the LPA, where a program is first searched for when no JOBLIB/STEPLIB is specified, is always treated as APF-authorized. The linklist, where the program is searched next, when it was not found in LPA, is likewise treated as APF-authorized if the effective IEASYSxx member in your parmlib specifies LNKAUTH=LNKLST.

SYSPLEX

The name of the sysplex the SYSTEM is a part of (if applicable).

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. The field length is 8 characters for compatibility with other NEWLIST types. When combined with the DATASET and VOLUME fields, this field uniquely identifies an entry in the NEWLIST TYPE=SENSDSN.

VOLSER, VOLUME

For non-VSAM data sets this field contains the volume serial of the data set. For VSAM data sets it is missing. When combined with the SYSTEM and DATASET fields, this field uniquely identifies an entry in the NEWLIST TYPE=SENSDSN.

VOLSER_OR_SMS

For non-VSAM data sets, this field contains the volume serial of the data set unless the volume is SMS-managed, in which case the field contains *SMS*. For VSAM data sets, the field is missing. When combined with the SYSTEM and DATASET fields, this field uniquely identifies an entry in the NEWLIST TYPE=SENSDSN.

SETROPTS: System-wide RACF Options in database

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•		

The SETROPTS NEWLIST (NEWLIST TYPE=SETROPTS) displays system-wide options as they are stored in the RACF database in the ICB (Inventory Control Block). This NEWLIST generates one entry per complex. A unique key is COMPLEX. This NEWLIST does not include an AUDITCONCERN field because the information is too extensive to report for the entire system. You can report on audit concerns using

the AUDIT NEWLIST. Unless otherwise noted, you can use all fields for SELECT and EXCLUDE processing as well as in the following output commands: LIST, SORTLIST, SUMMARY, and DISPLAY.

Field descriptions

The SETROPTS NEWLIST provides the following fields for reporting.

ADSP, SETRADSP, SYSTEMADSP

This RACF flag indicates whether Automatic Data Set Protection (ADSP) is in effect (due to a SETROPTS ADSP command). If set (ADSP=YES), RACF creates a discrete profile for each new data set created by users that have the ADSP attribute on their user profile or on their current connect group. If not set, individual user or connect group ADSP attributes are not honored. This field supports overtype.

AIM_DB_STAGE

This field contains the stage of implementation of the Application Identity Mapping feature of RACF.

APPLAUDIT

This RACF flag indicates whether APPC transactions will be audited through the APPL class. If set (APPLAUDIT=YES), APPC transaction start and end will be audited (if an APPL class profile is present and has success auditing specified). If not set, the APPC transaction start and end is not audited.

The option indicated by this flag can be set by a SETROPTS APPLAUDIT command. This field supports overtype.

AUDIT_GROUP

This flag indicates whether RACF is logging all RACF commands and DEFINE requests affecting profiles in the GROUP class. These commands are ADDGROUP, ALTGROUP, CONNECT, DELGROUP, and REMOVE. It reflects the SETROPTS AUDIT(GROUP) setting. This field supports overtype.

AUDIT_USER

This flag indicates whether RACF is logging all RACF commands and DEFINE requests affecting profiles in the USER class. These commands are ADDUSER, ALTUSER, CONNECT, DELUSER, PASSWORD and REMOVE. It reflects the setting SETROPTS AUDIT(USER). This field supports overtype.

BATCHALLRACF

This RACF flag indicates whether JES is only to accept jobs containing either a valid RACF userid and password or propagated RACF information. If set (BATCHALLRACF=YES), any job not containing this user identification fails. If not set, jobs without RACF userid runs with default authority, and have access according to UACC and the Global Access Table.

The option indicated by this flag can be set by a SETROPTS JES(BATCHALLRACF) command. This field supports overtype.

CATDSNS

This string indicates whether RACF prevents users from accessing uncataloged, new or system temporary data sets. It reflects an option set by a SETROPTS CATDSNS command. The following table documents the CATDSNS values, the corresponding SETROPTS commands, and their meanings.

Table 424. SETROPTS: CATSDNS values, associated SETROPTS command, and description

CATDSNS value	SETROPTS command	Meaning
No	SETROPTS NOCATDSNS	Uncataloged data sets are not protected from access
Warning	SETROPTS CATDSNS(WARNING)	Access to uncataloged data sets is allowed, but will result in a warning
Yes/Fail	SETROPTS CATDSNS(FAILURES)	Access to uncataloged data sets is only allowed to started tasks and SPECIAL users; access for other users will fail

This field supports overtype which means that authorized users can modify the field value through the ISPF interface.

CMDVIOL

This RACF flag indicates whether RACF is to log violations detected by RACF commands (due to a SETROPTS CMDVIOL command). If set (CMDVIOL=YES), command violations are logged. This field supports overtype.

COMPATMODE

This RACF flag indicates whether RACF is to allow users and jobs that do not have security labels on a system enforcing security labels (due to a SETROPTS COMPATMODE command). If set (COMPATMODE=YES), RACF allows users and jobs without security labels. This field supports overtype.

COMPLEX

The security complex name assigned to the security database. The complex name can come from the ALLOC COMPLEX parameter or default to a system name. It is the key for this record.

DASDVOL

This RACF flag indicates whether the DASDVOL class is active. If set (DASDVOL=YES), users that do not have ALTER access to a data set are still able to alter, rename, delete, dump and restore the data set if they have access to a profile in the DASDVOL class for the volume containing the data set.

Note: if DASDVOL is not active or if no profile covering the volume exists in the DASDVOL class, all users are granted access by DFDSS.

DLOGOPT

Auditing options for data sets (RACFclass=DATASET), due to a SETROPTS LOGOPTIONS command. The DLOGOPT values and the SETROPTS LOGOPTIONS auditing level are documented in the following table.

Table 425. SETROPTS: DLOGOPT values and associated SETROPTS LOGOPTIONS auditing level

DLOGOPT value	SETROPTS LOGOPTIONS auditing level
Always	ALWAYS
Failure	FAILURES
Never	NEVER

Table 425. SETROPTS: DLOGOPT values and associated SETROPTS LOGOPTIONS auditing level (continued)

DLOGOPT value	SETROPTS LOGOPTIONS auditing level
Profile	(determined by profile)
Success	SUCCESSES

Use the LOGOPT field of NEWLIST TYPE=CLASS to display auditing options for all classes.

EGN

This flag indicates whether Enhanced Generic Naming (EGN) is in effect (due to a SETROPTS EGN command). This field supports overtype.

ERASEONSCRATCH, EOS

String that indicates whether erase-on-scratch is in effect as a result of a SETROPTS ERASE command. If this option is in effect, data sets are physically erased when deleted or released for reuse. Table 426 lists the ERASEONSCRATCH values. Also see, the "ERASESECLEVEL" field.

Table 426. SETROPTS: ERASEONSCRATCH values and descriptions

ERASEONSCRATCH value	Meaning
All	All data sets are physically erased after delete as a result of a SETROPTS ERASE(ALL) command.
Lvl nnn	Physical erasure will be performed if the profile that protects the data set specifies ERASE or if the profile's security level is equal to or greater than the erase security level *nnn* as specified on the SETROPTS ERASE(SECLEVEL) command.
None	No data sets are physically erased after delete, even if the erase indicator in the data set profile is on (due to a SETROPTS NOERASE command).
Profile	The erase indicator in the data set profile is used to determine whether the data set is physically erased after delete (due to a SETROPTS ERASE(NOSECLEVEL) command).

Note: When migrated or backed up data sets are scratched from HSM owned DASD volumes, the field HSMERASE determines if HSM actually performs the erasure requested by the profile.

ERASESECLEVEL, SECLEVELERASE

String that indicates the security level at or above which all data sets are physically erased when deleted or released for reuse as a result of a SETROPTS ERASE(SECLEVEL) command. If the value is *None*, the ERASEONSCRATCH field determines erasure options. See "ERASEONSCRATCH." Otherwise, the value is a number representing the security level.

GENERICOWNER, GENOWN

Flag that indicates if restrictions on the creation of generic profiles are in effect as a result of a SETROPTS GENERICOWNER command. If the value is *Yes*, users can only create a generic profile more specific than any existing profile covering the same generic resource under the following conditions:

- The user has the SPECIAL attribute

- The user is the owner of the existing profile
- The profile is owned by a group and the user is group-SPECIAL in that group.
- The profile is owned by a user in a group and the current user is group-SPECIAL in that group.

This option does *not* apply to the class DATASET; for class DATASET, the CREATE authority determines who can create profiles. This field supports overtype.

GRPLIST, LISTGRP

This flag indicates whether list-of-groups processing is in effect (due to a SETROPTS GRPLIST command). If set (GRPLIST=YES), a user's authority to a resource is not based on the authority of the user's current connect group only, but on the highest authority of all groups the user is connected to. This field supports overtype.

HISTORY, PWDHISTORY

This string indicates the number of previous passwords stored by RACF (due to a SETROPTS PASSWORD(HISTORY) command). If set to '**No**', no password history is kept; otherwise, it contains a number in the range 1 to 32. This field supports overtype.

INACTIVE

This string indicates the number of days that a userid remains valid without being used (due to a SETROPTS INACTIVE command). If set to '**No**', users are never revoked because of lack of activity; otherwise, it contains a number in the range 1 to 255.

Note that inactive users are only revoked by RACF the next time user activity is attempted, for instance the next time the now inactive user tries to logon. Inactive users can be found using the CARLa script CKRLINAC. This field supports overtype.

INITSTATS

This flag indicates whether RACF statistics are updated by RACINIT processing (due to a SETROPTS INITSTATS command). This field supports overtype.

INTERVAL, PWDINTERVAL

This string indicates the maximum number of days a password remains valid (due to a SETROPTS PASSWORD(INTERVAL) command). If set to `No`, passwords never expire; otherwise, it contains a number in the range 1 to 254. This field supports overtype.

KERBLVL

This field contains the value of the SETROPTS KERBLVL setting, indicating the level of Kerberos support present on the system. It controls the types of encryption that can be used when setting up a Kerberos connection.

LVL1PREF

This string indicates whether RACF protection is in effect for data sets that have single-qualifier names (due to a SETROPTS PREFIX command). If set, it contains a 1- to 8-character first qualifier prefixed to the data set name to get the internal (resource) name. If empty, RACF protection for single-qualifier data sets is not in effect (due to a SETROPTS NOPREFIX command). This field supports overtype.

MINCHANGE

This field indicates the minimal number of days that must pass between a user's password changes (due to a SETROPTS PASSWORD(MINCHANGE()) command.) If set to '**No**', users can change their passwords more than once on the same day; otherwise, it contains a number in the range 1 to 254. This field supports overtype.

MIXEDCASE

This flag field indicates whether mixedcase passwords are used (due to a SETROPTS PASSWORD(MIXEDCASE) command.) This field supports overtype.

MLACTIVE

This string indicates whether RACF requires security labels to be present on all jobs, all resources defined in USER and DATASET, and all classes defined in the Class Descriptor Table (CDT) that require a security label. It reflects an option set by a SETROPTS MLACTIVE command. The following table documents the MLACTIVE values, the corresponding SETROPTS commands, and their meaning.

Table 427. SETROPTS: MLACTIVE values, corresponding SETROPTS commands, and descriptions

MLACTIVE value	SETROPTS command	Meaning
No	SETROPTS NOMLACTIVE	Security labels are not required
Warning	SETROPTS MLACTIVE(WARNING)	RACF allows jobs without a security label access to resources that do not have a security label, but issues a warning
Yes/Fail	SETROPTS MLACTIVE(FAILURES)	Security labels are required in all normal cases; privileged started tasks and SPECIAL users are allowed requests as long as data is not declassified

Classes in the Class Descriptor Table (CDT) that require a security label can be found using the SECLABEL field of NEWLIST TYPE=CLASS. This field supports overtype.

MLQUIET

This flag indicates whether RACF is to keep the system in a tranquil state (due to a SETROPTS MLQUIET command). If set (MLQUIET=YES), only started procedures, console operators, or SPECIAL users are able to logon, start new jobs, or access resources. This field supports overtype.

MLS

This string indicates whether RACF prevents users from declassifying data in a system using security labels. It reflects an option set by a SETROPTS MLS command. The following table documents the MLS values, the corresponding SETROPTS commands, and their meanings.

Table 428. SETROPTS: MLS values, corresponding SETROPTS commands, and descriptions

MLS value	SETROPTS command	Meaning
No	SETROPTS NOMLS	Users are allowed to declassify data
Warning	SETROPTS MLS(WARNING)	Users are allowed to declassify data, but any such action results in a warning
Yes/Fail	SETROPTS MLS(FAILURES)	Users are not allowed to declassify data

This field supports overtype.

MLSTABLE

This flag indicates whether the system has stabilized security labels (due to a SETROPTS MLSTABLE command). If set (MLSTABLE=YES), security labels can only be altered if MLQUIET is in effect. This field supports overtype.

MODELGDG

This flag indicates whether Generation Data Group (GDG) modeling is in effect (due to a SETROPTS MODEL(GDG) command). If set (MODELGDG=YES), the GDG base name, not the GDG generation name, is used to find the data set profile for the data set. This field supports overtype.

MODELGROUP

This flag indicates whether group modeling is in effect (due to a SETROPTS MODEL(GROUP) command). If set (MODELGROUP=YES), RACF uses a model profile to complete new group-named data set profiles. This field supports overtype.

MODELUSER

This flag indicates whether user modeling is in effect (due to a SETROPTS MODEL(USER) command). If set (MODELUSER=YES), RACF uses a model profile to complete new userid-named data set profiles. This field supports overtype.

NJEUSERID

This string indicates the userid to be used for SYSOUT or network jobs that are sent to the system without an RTOKEN or UTOKEN. The value of the string cannot be set to a userid defined in the RACF database.

The NJEUSERID can be set by a SETROPTS JES(NJEUSERID) command. The default value is a series of question marks (????????). This field supports overtype.

NOADDCREATOR

This flag indicates whether the system has to suppress the ALTER permit added by default to each newly created profile for the userid of the creator. This field supports overtype.

OPERAUDIT

This flag indicates whether RACF is logging all actions allowed only because a user has the OPERATIONS or group-OPERATIONS attribute. It reflects an option set by the SETROPTS OPERAUDIT command. This field supports overtype.

PRIMARY_LANGUAGE

This field indicates the RACF primary language setting as set by SETROPTR LANGUAGE(PRIMARY()).

PROTECTALL

This string indicates whether RACF protect-all processing is active (due to a SETROPTS PROTECTALL command). The following table documents the PROTECTALL values, the corresponding SETROPTS commands, and their meanings.

Table 429. SETROPTS: PROTECTALL values, corresponding SETROPTS commands, and descriptions

PROTECTALL value	SETROPTS command	Meaning
No	SETROPTS NOPROTECTALL	Users can access and create data sets that are not RACF-protected
Warning	SETROPTS PROTECTALL(WARNING)	Users can access and create data sets that are not RACF-protected, but any such action results in a warning
Yes/Fail	SETROPTS PROTECTALL(FAILURES)	Normal users are not allowed to access or create data sets that are not RACF-protected. Privileged started tasks and SPECIAL users are allowed to do so, but any such action results in a warning

This field supports overtype.

PWDRULE1

This string displays RACF password rule 1. RACF supports 8 different password rules, of which any one might be active or inactive (due to a SETROPTS PASSWORD(RULE)) command. If active, the password rule is of the form '**Length(min:max) Pattern**' or '**Length(max) Pattern**'. The Pattern is a string of **max** characters indicating what characters are valid at that position. The following table documents the possible character values and their meanings.

Table 430. SETROPTS: PWDRULE1 Character values and meanings

Pattern character	Meaning
*	Any character
$	National
A	Alphabetic
C	Consonant
c	Mixed consonant
L	Alphanumeric
m	Mixed numeric
N	Numeric
V	Vowel

Table 430. SETROPTS: PWDRULE1 Character values and meanings (continued)

Pattern character	Meaning
v	Mixed vowel
W	No vowel

Note that, when multiple password rules are active, RACF attempts to match a new password to *any* active rule, not *all* active rules. A password that is not accepted by one rule and accepted by another is therefore allowed by RACF.

PWDRULE2

This string displays RACF password rule 2. See the PWDRULE1 field.

PWDRULE3

This string displays RACF password rule 3. See the PWDRULE1 field.

PWDRULE4

This string displays RACF password rule 4. See the PWDRULE1 field.

PWDRULE5

This string displays RACF password rule 5. See the PWDRULE1 field.

PWDRULE6

This string displays RACF password rule 6. See the PWDRULE1 field.

PWDRULE7

This string displays RACF password rule 7. See the PWDRULE1 field.

PWDRULE8

This string displays RACF password rule 8. See the PWDRULE1 field.

RACFLEVEL, RACFLVL

A string that indicates the software level of RACF, for example: 'HRF7709'. This string is often tested by other products.

RACF_MLFSOBJ

This string indicates whether RACF requires security labels for files and directories. When the SECLABEL class is active, and MLFSOBJ is active, access to files and directories without security labels is denied except by trusted or privileged started tasks. Since HFS filesystems do not fully support security labels (except in read-only mode), conversion to zFS file systems is advisable before turning on this option. This field reflects the option set by a SETROPTS MLFSOBJ(ACTIVE|INACTIVE) command. This field supports overtype.

RACF_MLIPCOBJ

This string indicates whether RACF requires security labels for interprocess communications. When the SECLABEL class is active, and MLIPCOBJ is active, access to semaphores, message queues and shared memory without associated security labels is denied except by trusted or privileged started tasks. This field reflects the option set by a SETROPTS MLIPCOBJ(ACTIVE|INACTIVE) command. This field supports overtype.

RACF_MLNAMES

This string indicates whether the RACF name hiding function is in effect. This function has the following effects:

- Users cannot view the names of z/OS UNIX files and directories that their current security label does not give them authority to read.
- Users cannot view the names of data sets that a mandatory access check followed by a discretionary access check does not allow them to read.
- Users listing catalogs or directories cannot see the names of resources that they cannot currently read.
- Users cannot read a VTOC directly, unless they have been given authorization to the profile in the FACILITY class that protects the VTOC.

This field reflects the option set by a SETROPTS (NO)MLNAMES command. This field supports overtype.

RACF_SECLBYSYSTEM

This string indicates whether RACF allows security labels to be activated on a system image basis. When SECLBYSYSTEM is active, the SMF ID values specified in the member list of the profiles in the SECLABEL class will determine whether or not the security label is valid for each system. Security labels that are not valid for a system are considered inactive and cannot be used or listed by users without SPECIAL or AUDITOR on that system. This field reflects the option set by a SETROPTS (NO)SECLBYSYSTEM command. This field supports overtype.

REALDSN

This flag indicates whether RACF logging uses the real data set name (REALDSN=YES) or the naming-conventions name (REALDSN=NO) for logging purposes. It reflects an option set by the SETROPTS REALDSN command. This field supports overtype.

RETPD

This string specifies the RACF security retention period for tape data sets (due to a SETROPTS RETPD command). It is set to a number in the range 0 to 65533 for a tape data set that expires, and to 99999 for a tape data set that never expires. This field supports overtype.

REVOKE, PWDREVOKE

This string indicates the maximum number of consecutive invalid password attempts before a userid is revoked on the next invalid attempt (due to a SETROPTS PASSWORD(REVOKE) command). If set to '**No**', userids are never revoked because of invalid password attempts; otherwise, it contains a number in the range 1 to 254.

A REVOKE value of 5 means a userid is revoked at the *sixth* (not fifth) consecutive invalid password attempt. SPECIAL users are not revoked automatically after too many invalid password attempts. Instead, console message ICH301I is issued, and the operator must decide whether or not to revoke the SPECIAL user. This field supports the Overtype function which permits authorized users to edit the value from the ISPF interface.

RVARYSTATUSPWSET

This flag indicates whether the password for RVARY STATUS has been changed from the default value.

RVARYSWITCHPWSET

This flag indicates whether the password for RVARY SWITCH has been changed from the default value.

SAUDIT

This flag indicates whether RACF is logging all commands issued by users having the SPECIAL or group-SPECIAL attribute. It reflects an option set by the SETROPTS SAUDIT command. This field supports overtype.

SECLABELAUDIT

This flag indicates whether security label auditing is in effect (due to a SETROPTS SECLABELAUDIT command). If set (SECLABELAUDIT=YES), RACF uses the security label's auditing options in addition to the profile's auditing options for all access attempts. If no auditing options are set on the security label's profile, this option has no effect. This field supports overtype.

SECLABELCONTROL

This flag indicates whether security label control is in effect (due to a SETROPTS SECLABELCONTROL command). If set (SECLABELCONTROL=YES), the only users allowed to use the SECLABEL keyword of RACF commands are:

- SPECIAL users (all RACF commands)
- group-SPECIAL users (ADDUSER and ALTUSER commands)

If not set, all users with at least READ authority on the SECLABEL's profile can change profiles with this SECLABEL. This field supports overtype.

SECLEVELAUDIT

This string indicates whether security level auditing is in effect (due to a SETROPTS SECLEVELAUDIT command). If set to '**None**', auditing is not based on security levels; otherwise, it specifies the security level above which all access attempts are audited. This field supports overtype.

SECONDARY_LANGUAGE

This field indicates the RACF secondary language setting as set by SETROPTR LANGUAGE(SECONDARY()).

SESSIONINTERVAL, SESSINT

This string specifies the maximum session key interval that can be specified by RDEFINE or RALTER. It is set to a value in the range 1 to 32767 if session keys expire (SETROPTS SESSIONINTERVAL command); to '**None**' if no limit is set (due to a SETROPTS NOSESSIONINTERVAL command). This field supports overtype.

TAPEDSN

This flag indicates whether tape data set protection is in effect (due to a SETROPTS TAPEDSN command). If set (TAPEDSN=YES), RACF can protect tape data sets as well as tape volumes. This field supports overtype.

TAPEVOL

This flag indicates whether the TAPEVOL class is active.

If TAPEVOL is inactive, RACF is not able to guarantee the integrity of tapevolumes. Even if TAPEDSN is active, and even if you have a tape management system that assures 44 character data set name integrity (a tape only physically contains the last 17 in its data set header labels), it is still possible to circumvent security because of the fact that there is no protection between data sets on one tape. If you have access to one data set on a tape, you can use a non-APF-authorized program to access information of *all* data sets on the tape. So if you have TAPEVOL inactive, anyone can add an empty data set to that tape (unless it is completely full), and then access the other data sets.

The only way a tape management system can prevent this is by always checking access to the tape based on the first data set on the tape or by preventing multiple data sets on a tape.

Another protection that is inactive if TAPEVOL is off, is the protection against Bypass Label Processing (BLP). If TAPEVOL is off, no RACHECKS are done by DFP on the FACILITY profile ICHBLP.

TERMINAL

This flag indicates whether the TERMINAL class is active (due to a SETROPTS CLASSACT(TERMINAL) command).

TERMUACC

This string indicates the default universal access authority associated with undefined terminals (due to a SETROPTS TERMINAL command). It can have the values 'NONE' and 'READ'. This field supports overtype.

UNDEFINEDUSER

This string indicates the userid to be used for local jobs that enter the system without a userid; it might not be set to a userid defined in the RACF database.

The UNDEFINEDUSER can be set by a SETROPTS JES(UNDEFINEDUSER) command; the default is '**++++++++**'.

If a RACF version before 1.9 is used, this is set to '**n/a**'. This field supports overtype.

WARNING, PWDWARNING

This string indicates the maximum number of days before the expiration of a password, at which RACF is to issue a warning message to a user (due to a SETROPTS PASSWORD(WARNING) command). If set to '**No**', no warning is issued; otherwise, it contains a number in the range 1 to 255. This field supports overtype.

WHENPROGRAM, PROGRAM

This flag indicates whether RACF program control is active (due to a SETROPTS WHEN(PROGRAM) command). If set (WHENPROGRAM=YES), RACF protection is in effect for access to load modules and Program Control to Data Sets (PADS), independently of whether the PROGRAM class is active or not. This field supports overtype.

XBMALLRACF

This flag indicates whether JES2 is to test jobs to be run with an execution batch monitor for either a valid RACF userid and password or propagated RACF information. If set (XBMALLRACF=YES), all jobs not containing this user identification fail.

The option indicated by this flag can be set by a SETROPTS JES(XBMALLRACF) command. This field is modifiable.

SETROPTS_CLASS: RACF Class Settings in database

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•		

The SETROPTS_CLASS NEWLIST (NEWLIST TYPE=SETROPTS_CLASS) lists class-specific SETROPTS options as they are stored in the RACF database ICB (Inventory

Control Block). Unless otherwise stated, all fields can be used for SELECT/EXCLUDE processing as well as in the output commands (LIST, SORTLIST, DISPLAY and SUMMARY).

It generates one entry per so-called POSIT value in the database; a unique key is COMPLEX POSIT. It is closely related to the NEWLIST TYPE=CLASS reports, in the sense that those display the incore settings from RCVT bits that supposedly should match those in the database. The main advantage of SETROPTS_CLASS over CLASS is that you do not need to have a CKFREEZE file with the proper content. This might be the case under VM, for instance, or if you are analyzing an old backup of a RACF database, or if you are analyzing the security of a system where you could not run zSecure Collect. Another advantage of SETROPTS_CLASS is that you do not see modifiable fields that in fact cannot be set independently since the classes have the same POSIT value. On the other hand, the advantage of TYPE=CLASS is that it combines the POSIT-based class settings with information from the CDT (Class Descriptor Table), like the actual class name. See "CLASS: RACF Class Descriptor Table" on page 989.

Class activity options for class DATASET do not have a POSIT number, but are nonetheless displayed. They can also be displayed with NEWLIST TYPE=SETROPTS as well. Note that site-defined classes will not display a class name, since there is no default class name for the site-defined POSIT values.

Field descriptions

The `SETROPTS_CLASS NEWLIST` provides the following fields for reporting.

ACTIVE

RACF protection for this class is active (due to a SETROPTS CLASSACT command). This field supports overtype.

AUDIT

Command auditing for this class is active (due to a SETROPTS AUDIT command). This field supports overtype.

AUDITCONCERN, CONCERN

This field returns a concatenation of audit concerns for the class. The following table shows the default audit priorities for active and non-active classes and the audit concerns. It is sorted by highest audit priority without a policy statement.

Table 431. SETROPTS_CLASS: audit priorities and associated audit concern descriptions for active and non-active classes

Audit priority active class	Audit priority non-active class	Audit concern
25	15	GENCMD off but GENERIC on
15	2	GENCMD on but GENERIC off
15	2	Violations not logged - LOGOPTIONS(NEVER)
5.	1	SETROPTS GLOBAL inactive, but profile present

The priority is 40 higher if the concern is not compliant to the policy that has been selected. A priority of 0 means the concern is not issued unless the policy has explicitly been requested.

The following audit concerns have been defined:

GENCMD off but GENERIC on

For this class the generic command processing has been turned off, while the class is being used as a generic class. Newly created profiles would turn out to be DISCRETE profiles, even if they contain generic characters. This situation should not occur.

GENCMD on but GENERIC off

The creation and deletion of generic profiles is possible, but RACF does not use them for access control. This could lead to data that is unprotected against expectations. This situation is intended for use when migrating from discrete profiles to generic profiles.

Violations not logged - LOGOPTIONS(NEVER)

This is undesirable since violations would not be journalled to SMF. Journalling violations and follow up tracking is critical to securing the resources within an installation.

SETROPTS GLOBAL inactive, but profile present

This suggests that somebody wanted to add entries for this class to the global access table, but did not succeed in doing so.

AUDITPRIORITY

This field returns the audit priority for the profile. See field AUDITCONCERN for a table with the concerns and their priorities. The actual audit priority can be higher because of e.g. a SIMULATE POLICY C2 statement.

DEFAULT_CLASS

Most commonly used class name that is controlled by the current POSIT value, as documented by IBM. Note that site-defined classes will not display a class name, since there is no default class name for the site-defined POSIT values. The link between POSIT value and class name is not stored in the RACF database, but in a load module (the Class Descriptor Table). See NEWLIST TYPE=CLASS for the mapping that a specific system uses when deploying the database.

COMPLEX

The security complex that contains the system. The complex name can come from the ALLOC COMPLEX parameter or default to a system name.

DESCRIPTION

This 64 character field returns a short explanation of the purpose of the class.

GEN

This string is set to '**Discrete**' if generic profiles in this class are not checked, and is empty otherwise.

GENCMD

Generic profile command processing for this class is active (due to a SETROPTS GENCMD or a SETROPTS GENERIC command). This field supports overtype.

GENERIC

Generic profile checking for this class is active (due to a SETROPTS GENERIC command). This implies that generic command processing for this class is active. This field supports overtype.

GENLIST

This flag indicates that this class has been GENLISTed, for example, that generic profiles for this class are shared in-storage (due to a SETROPTS GENLIST command). If this flag is set, the RACLIST flag cannot be set. This field supports overtype.

GLB

String indicating global access checking activity. It is set to `Glob` if global access checking is active, and blank if global access checking is inactive.

GLOBAL

Flag indicating Global Access Checking activity. Undefined if no Global Access checking is allowed, set if Global Access checking is active, and not set if Global Access checking is inactive. This field supports overtype.

LOGOPT

Auditing options for this class, due to a SETROPTS LOGOPTIONS command. The LOGOPT values and the SETROPTS LOGOPTIONS auditing level are documented in the following table.

Table 432. SETROPTS_CLASS: LOGOPT values and associated SETROPTS LOGOPTIONS auditing levels

LOGOPT value	SETROPTS LOGOPTIONS auditing level
Always	ALWAYS
Failure	FAILURES
Never	NEVER
Profile	(determined by profile)
Success	SUCCESSES

This field supports overtype.

POSIT

Options set id. This is a number in the range 0 to 1023 identifying a set of SETROPTS options that govern the activity of this class and all other classes having the same POSIT value. Whenever a SETROPTS command is issued for any class with a specific POSIT value, it applies to all classes with that value.

PROTECT

This is a string summarizing the protection options for this class and is based on the ACTIVE and AUDIT flags. The PROTECT values and the related values of the ACTIVE and AUDIT flags are documented in the following table.

Table 433. SETROPTS_CLASS: PROTECT values and related ACTIVE and AUDIT flag values

PROTECT value	ACTIVE flag	AUDIT flag
Inactive	NO	-
Noaudit	YES	NO
(blank)	YES	YES

RACLIST

This flag indicates that this class has been RACLISTed, for example, that both generic and discrete profiles for this class are shared in-storage (due to a

SETROPTS RACLIST(class) command). If this flag is set, the GENLIST flag cannot be set. This field supports overtype.

STATS

Flag indicating whether statistics are collected for this class (due to a SETROPTS STATISTICS command). This field supports overtype.

SMF: SMF records

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•	•			•	•	•

This section documents the fields for NEWLIST TYPE=SMF. Most fields can be used for SELECT/EXCLUDE processing as well as in the output commands (LIST, SORTLIST, DISPLAY and (D)SUMMARY), but there are some exceptions that can only be used for SELECT/EXCLUDE, or can only be used for output. The exceptions are noted in the description of the fields.

Most fields are not found in all SMF record types. The description of each field notes in which SMF record types the field is found. in addition, the end of this section contains a cross-reference table of fields and SMF record types.

- "Field descriptions"
- "Supported record types" on page 1388

Field descriptions

The `SMF NEWLIST` provides the following fields for reporting.

ACCESS

RACF allowed access. This field is found only in RACF processing records (SMF record types 80 and 83 subtype 1) written for a RACHECK (EVENT=ACCESS). Access granted through the global access table is not logged in this way.

Possible ACCESS values are documented in Table 434(increasing sort order).

Table 434. SMF record ACCESS field - available values

ACCESS value
N/A
NONE
EXECUTE
READ
UPDATE
CONTROL
ALTER
OWNER

The value N/A indicates that the preceding security label check already failed, so that the access level is not the cause of the failure

ACTION

The Action field is the action which caused the record to be created. This field is supported for the following SMF record types:

- DFSMS Statistics and Configuration records (SMF record type 42)
- INPUT (SMF record type 14)
- OUTPUT Data Set Activity (SMF record type 15)

For DFSMS Statistics and Configuration records, subtype 3 (SMF record type 42) Table 435 lists the possible action values. Only one value is returned.

Table 435. DFSMS Statistics and Configuration records - actions causing record creation

Record subtype	Actions that create records
3	ACTIVATE, ENF, VARY SMS, SAVEACDS
20	INITIALIZE
21	DELETE
22	ADD, CHANGE, DELETE
23	CREATE, EXTEND, UPDATE, READ, DELETE
24	ADD or REPLACE
25	RENAME
26	CREATE, REMOVE, RENAME

APPL

Application name as provided to RACF or the R_auditx service by the application. This field is found in RACF processing records (SMF record types 80 and 83 subtype 1) written for a RACINIT or RACHECK (EVENT=(RACINIT ACCESS)) and in R_auditx records (SMF record type 83 subtypes 2 and higher). It is also found in CICS records (SMF record type 110).

Note: This value of this field is determined by the application. It is not necessarily the same as the name of the application used for logging on.

AUTH_USER_HOSTNAME

This field is found in RACF processing and R_auditx records (SMF record type 80 and 83) and corresponds with RACF_SECTION(394) or RACF_SECTION(12), respectively. It contains the hostname cached by the Identity Context Extension (ICTX).

AUTH_USER_NAME

This field is found in RACF processing and R_auditx records (SMF record type 80 and 83) and corresponds with RACF_SECTION(392 or 424 if 392 is absent) or RACF_SECTION(10), respectively. It contains the authenticated user name cached by the Identity Context Extension (ICTX).

AUTH_USER_OID

This field is found in RACF processing and R_auditx records (SMF record type 80 and 83) and corresponds with RACF_SECTION(395) or RACF_SECTION(13), respectively. It contains the authentication object identifier cached by the Identity Context Extension (ICTX).

AUTH_USER_REGNAME

This field is found in RACF processing and R_auditx records (SMF record type 80 and 83) and corresponds with RACF_SECTION(393) or RACF_SECTION(11), respectively. It contains the registry name cached by the Identity Context Extension (ICTX).

BOX_SERIAL

This field describes the DASD unit volume serial number and device id for the data set. This field can be used to disambiguate between DASD volumes with the same VOLSER. See also "BOX_SERIAL field for DASDVOL report" on page 1014.

CATALOG

This field describes the catalog used. This field is found only in ICF processing records (SMF record types 36, 61, 65 and 66) and VSAM data set open and close records (SMF record types 62 and 64).

CERTIFICATE_ISSUER

This field is found in RACF processing records (SMF record type 80) and R_auditx records (SMF record type 83 subtypes 2 and higher) and corresponds with RACF_SECTION(332) or RACF_SECTION(2), respectively. If the user that caused this record to be written has authenticated himself to the system with a digital certificate, this field contains the distinguished name of the issuer of the certificate.

CERTIFICATE_LABEL

This repeated field is only found in RACF processing records (SMF record type 80) for RACDCERT events. It contains the certificate labels associated with this event. This field can contain up to 32 bytes of text, and is by default shown with that length.

CERTIFICATE_SERIAL

This field is only found in RACF processing records (SMF record type 80) and corresponds with RACF_SECTION(318). It contains the serial number of the certificate that is associated with this event. By default, this field is shown with a length of 10, though the contents can reach a length of 255 characters.

CERTIFICATE_SUBJECT

This field is found in RACF processing records (SMF record type 80) and R_auditx records (SMF record type 83 subtypes 2 and higher) and corresponds with RACF_SECTION(331), or RACF_SECTION(1) respectively. If the user that caused this record to be written has authenticated himself to the system with a digital certificate, this field contains the distinguished name of the subject of the certificate.

CICS_MONITOR_CLASS

For CICS monitoring records (SMF record type 110, subtype 1), this field returns the class of the monitoring record. The value is returned in decimal format. Table 436 provides a list of values and descriptions.

Table 436. CICS_MONITOR_CLASS - value

Value	Description
1	Dictionary record
3	Performance record
4	Exception record

Table 436. CICS_MONITOR_CLASS - value (continued)

Value	Description
5	Transaction resource record

The CICS_MONITOR_CLASS field is supported in both the super and sub records. The field is empty if the record is not a CICS monitoring record.

CICS_PERFORMANCE_DATA

For CICS Monitoring Performance class subrecords, (SMF 110, subtype 1, class 3), this field contains the field names and associated values for the CICS performance data stored in the record. The information reported is derived from the CICS data-dictionary and field connectors in the Performance Data section of the CICS monitoring record. If a performance data field does not contain a value, the field is not reported.

If the CICS record contains user-defined fields, the fields only display in the output if a dictionary has been read from SMF.

See the CICS monitoring facility documentation in the CICS Transaction Server for z/OS Information Center for more information: https://publib.boulder.ibm.com/infocenter/cicsts/v4r1/topic/com.ibm.cics.ts.home.doc/welcomePage/welcomePage.html.

CICS_SPECIFIC_APPL

For CICS monitoring records (SMF record type 110, subtype 1), this field identifies the specific CICS instance from which the data in the record was obtained. The value is derived from the CICS monitoring record field SMFMNSPN (Specific APPLID). Multiple CICS instances can be combined into a system using the generic APPLID name which is found in the APPL field.

CICS_TERM

This field returns the CICS terminal name associated with the transaction. This field is only supported for CICS monitoring performance sub records. (SMF 110 subtype 1, sub class 3). If this information is not available, this field is not reported.

CICS_TTYPE

For CICS monitoring performance subrecords, (SMF 110, subtype 1, class 3), this field returns a value indicating the type of transaction start (Start Code or Start Type). Table 437 shows the possible values for the CICS_TYPE field.

Table 437. CICS transaction start code or types

Value	Description
TO	The transaction was started (attached) by input of the transaction ID from the terminal user.
S	Attached by automatic transaction initiation (ATI) without data.
SD	Attached by automatic transaction initiation (ATI) with data.
QD	The transaction was started (attached) because the trigger level of an intrapartition transient data queue was reached.
U	The transaction was started (attached) by a CICS internal function generally as a result of some user request.
TP	Attached from terminal (TCTTE) transaction ID.

Table 437. CICS transaction start code or types (continued)

Value	Description
SZ	Attached by the Front End Programming Interface (FEPI).

If this information is not available, the field is not reported.

For information about transaction Start types, see the CICS-related SMF data section in the CICS Performance Analyzer for z/OS Report Reference.

CLASS

SAF class name. This field is found in the following record types:

- RACF processing and R_auditx records (SMF record types 80 and 83)
- Program signature verification records (SMF record type 86)

The CLASS field is derived for the following record types:

- SMF record types 14, 15, 17, 18, 30, 42, 60, 61, 62, 64, 65, and 66.
- HSM function statistics records.

For those SMF record types for which the SAF class is derived, the class is USER (for SMF record type 30), DATASET (when a resource name is found), or missing.

COMPCODE, COMPLETION_CODE

This field describes a job or step completion code. It is available in SMF record types 4, 5, and 30. It can describe a system abend code, a user abend code, or a return code (on successful completion). The COMPCODE field can have the following layouts:

Table 438. SMF record COMPCODE field - values for output processing

SELECT/EXCLUDE	Output code	Exploded output	Meaning
ACCESS RESOURCE	Ac	Resource	Access to the resource is being audited due to the AUDIT option, a logging request from the RACHECK exit routine, or because the operator granted access during *failsoft* processing
APPLAUDIT	Ap	Applaudit	Entity audited due to SETROPTS APPLAUDIT
CLASS	Cl	Class	SETROPTS AUDIT(class) - Changes to this class of profile are being audited
CMDVIOL	Vi	CmdViol	Violation detected in command and CMDVIOL is in effect
COMMAND ALWAYS	Cm	Command	RVARY or SETROPTS command issued: these commands are always audited
COMPATMODE COMPAT	Co	Compatmode	Entity audited due to SETROPTS COMPATMODE

Table 438. SMF record COMPCODE field - values for output processing (continued)

SELECT/EXCLUDE	Output code	Exploded output	Meaning
GLOBALAUDIT GLOBAL AUDITOR	G	Globalaudit	Access to entity being audited due to GLOBALAUDIT option
LOGOPTIONS	O	Logoptions	Class being audited due to SETROPTS LOGOPTIONS
NONE	blank	blank	No REASON value present in SMF record.
OMVS_AUTHORITY	Oa	OMVS authority	Audited because user does not have appropriate authority in OpenEdition MVS
OMVS_UNDEFINED	Ou	OMVS undefined	Audited because user not defined to OpenEdition MVS.
RACINIT	R	RACINIT failure	RACINIT failure
SECLABELAUDIT SECLABEL	Sl	Seclabel	Entity audited due to SETROPTS SECLABELAUDIT
SECLEVEL SECAUDIT	L	Seclevel	Entity audited due to SETROPTS SECLEVELAUDIT
SPECIAL	Sp	Special	SPECIAL or OPERATIONS users being audited (due to SETROPTS SAUDIT or SETROPTS OPERAUDIT).
USER	U	User	User being audited (due to ALTUSER UAUDIT)
VMEVENTVMAUDIT	Vm	VM event	VMEVENT auditing

Note: For SELECT/EXCLUDE processing, only the =, <>, and ¬= relational operators can be used.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. This value can come from the ALLOC COMPLEX parameter or default to a system name.

COMPSTAT, COMPLETION_STATUS

This field describes a job or step completion status. It is available in SMF record types 4, 5, 30, and 110 subtype 1, class 3 (CICS monitoring records performance class data). It can have the values described in Table 439 on page 1282.

Table 439. SMF record COMPLETION_STATUS field descriptions

COMPSTAT value	Types	Explanation
ABEND	4, 5, 30	User or system abend
FLUSHED	4, 30	Job or step was flushed
RC<>0	4, 5, 30	Nonzero result code, but not abended or flushed

CSSMTP_BADSPOOLDISP
A field indicating what the CSSMTP application should do with a JES spool file in case errors were encountered when processing the spool file. The field can have one of the following values:

- *Hold* Change the disposition of the spool file to HOLD so that CSSMTP cannot process it.
- *Delete* Delete the bad spool file.

The bad spool file disposition field reflects the value of CSSMTP configuration statement BadSpoolDisp parameter.

CSSMTP_DATETIME

Date and time when the reader recognized the JOB card for the CSSMTP job.

CSSMTP_EXTWRTNAME
External writer name, identifying the instance of CSSMTP which wrote the SMF record. The extermal writer name field reflects CSSMTP configuration statement ExtWrtName parameter, or, if there is no such statement, it reflects the CSSMTP job name.

CSSMTP_ CKPFILE
Name of the file where checkpoint information is saved.

CSSMTP_CN_ESMTP
The type of the server associated with the connection. The field can have one of the following values:

- *SMTP* indicates it is an SMTP server.
- *ESMTP* indicates it is an ESMTP (Extended SMTP) server.

CSSMTP_CN_FIPS140
Flag field indicating whether the connection is on FIPS compliance level 140.

CSSMTP_CHECKPOINTING
Specifies how the CCSMTP checkpoint records are used when CCSMTP starts. The field value is only available if the CSSMTP start option *-f* has been specified and the CSSMTP started procedure includes a CHKPOINT DD statement. This field can have the following values:

WarmStart
Indicates that checkpoint records are employed to restart JES spool files at their last known status when CSSMTP restarts

ColdStart
Indicates that any checkpoint records from the previous run of CSSMTP are flushed when CSSMTP restarts.

Unavailable
Indicates that checkpointing is not performed.

CSSMTP_CN_LOCAL_IP
Local IP address of a connection.

CSSMTP_CN_LOCAL_PORT
Local port of a connection.

CSSMTP_CN_REMOTE_IP
Remote IP address for a connection.

CSSMTP_CN_REMOTE_PORT
Remote port for a connection.

CSSMTP_CN_TLS_SSL_PROTO
AT-TLS SSL protocol employed with a connection. This field can have one of the following values:

- N/A Not applicable because TLS/SSL is not employed.
- *SSL2* SSL version 2
- *SSL3* SSL version 3
- *TLS1* TLS version 1 and
- *TLS1.1* TLS version 1.1

CSSMTP_CN_TLSNC
AT-TLS negotiated cipher employed with a connection.

CSSMTP_CONFIG_FILE
Name of the file with CSSMTP configuration statements.

CSSMTP_CONSOLE
Name of the console that issued the command.

CSSMTP_DEAD_LETTER_ACTN
The action CSSMTP should take when a dead letter is detected. The field can have one of the following values:

- *Delete* Do not save the dead letter to a z/OS UNIX file system.
- *Store* Store the mail message to the directory reported in the CSSMTP_DEAD_LETTER_DIR field

The CSSMTP_DEAD_LETTER_ACTN field returns the value from the CSSMTP configuration statement UNDELIVERABLE parameter DeadLetterAction.

CSSMTP_ DEAD_LETTER_DIR
This field represents the z/OS UNIX directory that CSSMTP uses for storing dead letters when the value of the CSSMTP_DEAD_LETTER_ACTN field is *Store*. The CSSMTP_DEAD_LETTER_DIR field reflects the value of the CSSMTP configuration statement UNDELIVERABLE parameter DeadLetterDirectory.

CSSMTP_DOMAIN_NAME
Domain Name used for a resolver MX query. This field reflects the value of the CSSMTP configuration statement TargetServer parameter TargetMx.

CSSMTP_HOST_NAME
Host name or fully qualified host name used for a resolver A or AAAA query. This field reflectsthe value of the CSSMTP configuration statement TargetServer parameter TargetName.

CSSMTP_LOGFILEC
CSSMTP client log file name.

CSSMTP_LOGLEVEL
The level of logging and tracing. The field reflects CSSMTP configuration statement LogLevel parameter.

CSSMTP_MAIL_ADMIN_MBOX
Repeated field with up to four e-mail addresses. These are the administrator

addresses to which CSSMTP delivers reports for certain errors. If the field is empty, no e-mail addresses have been configured to send a report. Each field value reflects the value of the CSSMTP configuration statement `MailAdministrator` parameter.

CSSMTP_MH_CMD_ERROR
Mail header text of command in error.

CSSMTP_MH_DATE
Mail header `Date` value.

CSSMTP_MH_ERROR_TEXT
Mail header error message text.

CSSMTP_MH_FROM
Mail header `Mail From` value.

CSSMTP_MH_MSGID
Mail header `Message-id` value.

CSSMTP_MH_RCPT_REPLY
Mail header `Reply to RCPT TO` value.

CSSMTP_MH_REPLY_TO_ERROR
Mail header text of reply to command in error.

CSSMTP_MH_SUBJECT
Mail header `Subject` value.

CSSMTP_MH_TO
Mail header `RCPT TO` value.

CSSMTP_REPORT
Action taken for reporting problems with JES spool files. The field can have one of the following values:

- *None* No error reports are created.
- *Admin* Error reports are sent to the configured mail administrators.
- *Sysout* CSSMTP creates a sysout file that contains the error report.

The field reflects the value of the CSSMTP configuration statement `REPORT` parameter.

CSSMTP_RTN_TO_MAIL_FROM
Flag field that indicates if CSSMTP sends an undeliverable mail notification to the originator when mail delivery fails. The field reflects the value of the CSSMTP configuration statement `UNDELIVERABLE` parameter `ReturnToMailFrom`.

CSSMTP_SMF119
Repeated field indicating which SMF type 119 subtype 48 to 52 records are written by CSSMTP.

- *Config* indicates configuration records (subtype 48) are written.
- *Connect* indicates connection records (subtype 49) are written.
- *Mail* indicates mail message records (subtype 50) are written.
- *Spool* indicates spool records (subtype 51) are written.
- *Stats* indicates statistical records (subtype 52) are written.

The absence of any of these values indicates that SMF type 119 records of the corresponding subtype are not written. The `CSSMTP_SMF119` field reflects the value of the parameters of the CSSMTP configuration statement `SMF119`.

CSSMTP_SI_SYSTEM
System name of the MVS image where the job output was created.

CSSMTP_SI_SYSTEM
System name of the MVS image where the job output was created.

CSSMTP_STACK
The name of the job employed to start the TCP/IP stack. In a common INET configuration, CCSMTP uses this job as a socket stack and for resolver functions. If CSSMTP_STACK is empty, the TCP/IP job name is either specified by the environment variable _BPXK_SETIBMOPT or no affinity is used in a common INET configuration.

CSSMTP_TS_DSTIP
Repeat group field. The IPv4 or IPv6 address of a target server to which CSSMTP connects. The value of the field reflects the CSSMTP configuration statement: TargetServer parameter, TargetName, TargetIP, or TargetMx.

CSSMTP_TS_INDEX
Repeat group field. Numerical field which indicates the order of the target server in the repeat group.

CSSMTP_TS_NAME
Repeat group field. The host name or fully qualified host name of a target server to which CSSMTP establishes a connection for sending mail. If the value of the CSSMTP_TS_TYPE field is *ADDRESS*, the value of the CSSMTP_TS_NAME field is a formatted IP address. The field reflects the value of the CSSMTP configuration statement TargetServer parameter TargetName, TargetIP, or TargetMx.

CSSMTP_TS_PORT
Repeat group field. The port that CSSMTP uses to connect to a target server. This port must match the listening port number used by the target server. The default port is 25. The field reflects the value of the CSSMTP configuration statement TargetServer parameter ConnectPort.

CSSMTP_TS_SECURE
Repeat group field. A flag field indicating whether Transport Layer Security (TLS) is required between CSSMTP and a target server. The field reflects the value of the CSSMTP configuration statement TargetServer parameter Secure.

CSSMTP_TS_TYPE
Repeat group field. Indicates the type of target server to which CSSMTP connects. The field indicates if the CSSMTP configuration statement TargetServer included a TargetName, TargetIP, or TargetMx parameter. The field can have one of the following values:

- *Address*. The CSSMTP configuration statement TargetServer included a TargetIP parameter.
- *Name*. The CSSMTP configuration statement TargetServer included a TargetName parameter.
- *MX*. The CSSMTP configuration statement TargetServer included a TargetMx parameter.

CSSMTP_USEID

User-defined identification field taken from the common exit parameter area, not from the USER=*parameter* on the job statement.

CSSMTP_USEREXIT
This field indicates whether CSSMTP calls the CSSMTP exit program to interrogate data that is sent to CSSMTP from the JES spool data set. If the

program is called, the field indicates which exit facility is used to call it. The field can have one of the following values:

- *NONE* Do not call the CSSMTP user exit.
- *VERSION2* Call the user exit using the exit facility token name EZBTCPIPSMTPEXIT.
- *VERSION3* Call the user exit using the exit facility token name EZATCPIPCSSMTPV3.

The field reflects CSSMTP configuration statement USEREXIT parameter.

DATASET, DSNAME, DSN

Data set name. This field is found in the following record types:

- Data set activity records (SMF record types 14, 15, 17, 18, 62 and 64)
- JES2 spool offload records (SMF record type 24)
- Catalog activity records (SMF record types 60, 61, 63, 65, 66, 67 and 68)
- RACF processing records (SMF record types 80 and 83 subtype 1)
- ACF2 data set use records
- TSS processing records (SMF record type 80)
- HSM function statistics records
- DB2 type 102 subtype/IFCid 34, 38, 39, 40, 104, 114, 119, 220, 258, and 362
- CSSMTP configuration records (SMF record type 119 subtype 48)
- DFSMS statistics and configuration records (SMF record type 42)

The DATASET field reflects the use of an actual data set. So RACF commands like PERMIT specifying a generic profile will NOT result in this field being filled. See also RESOURCE and PROFILE.

This is a repeated field, though only records describing a data set rename and some CSSMTP configuration records (SMF record type 119 subtype 48) contain more than one data set name

DATE

This field is present in all record types and contains the date the SMF record was written, in European format–08Oct2001 or 8 Oct 2001, for example. For detailed instructions on how to use this field in SELECT/EXCLUDE specifications, see “Date fields” on page 903.

DATETIME

This field is present in all SMF records and contains both the date and time the record was written. For detailed instructions on how to use this field in SELECT/EXCLUDE specifications, see “Combined date and time fields” on page 904.

DB2_APPL_USERID

This field contains the original application userid, as passed by Websphere Application Server, version 7.0. The default length of the field is 16, the maximum length 128. This field can be in UTF-8. You need an output file in UTF-8 encoding to be able to see all possible values. Conversion to EBCDIC is done when needed, but can cause information loss. The field is filled in for SMF type 100, 101, and 102 if the optional correlation header section is present in the SMF record and the field contains non-blank, non-null information. This processing behavior is the case for most subtypes.

DB2_AUTHID

This field contains the DB2 primary authorization id. This might or might not be identical to the USER field. Typically, the USER field is only filled in for some DB2 SMF record subtypes on a DB2 8.1 or higher system where DB2 is configured with a SAF interface, while the primary authorization id is always filled in. DB2 subsystem level tasks events often show SYSOPR as the primary authorization id. The default length for this field is 8, the maximum length is 128. This field can be in UTF-8. You need an output file in UTF-8 encoding to be able to see all possible values. Conversion to EBCDIC is done when needed, but might cause information loss. The field is filled in for SMF type 100, 101, and 102 if the optional correlation header section is present in the SMF record and the field contains non-blank, non-null information. This processing behavior is the case for most subtypes.

DB2_COMMAND

This field contains a DB2 subsystem command (like -START TRACE or -STOP TRACE), or an SQL command. The default length of the field is 150, the maximum length 32760. This field can be in UTF-8. You need an output file in UTF-8 encoding to be able to see all possible values. Conversion to EBCDIC is done when needed, but can cause information loss. This field value is returned for SMF type 102 subtype/IFCid 4, 5, 63, 90, 92, 97, 140, 141, 142, 145, 270, 350, (if non-blank and not nulls).

DB2_CONNECTION

This field is meant to identify sequences of SMF records that apply to the same "session" connecting a user to DB2. These connections can take place through connection types like BATCH, IMS, TSO, and so on. The connection name is a readable string constructed from the following header fields in sequence as far as they are not the same value as already printed.

1. DB2 subsystem name (standard header),
2. DB2 location name (standard header),
3. network id (standard header),
4. LU name (standard header),
5. data sharing group name (data sharing header),
6. data sharing group member name (data sharing header),
7. connector type (correlation header),
8. connector name (correlation header),
9. original operator id (correlation header),
10. end-user workstation name (correlation header),
11. end-user transaction name (correlation header),
12. end-user userid (correlation header),
13. remote requestor location name (distributed header),
14. DRDA® server name (distributed header),
15. product name of application requestor (distributed header).

The default length of the field is 132. The maximum length is 32760. This field can be in UTF-8. You need an output file in UTF-8 encoding to be able to see all possible values. Conversion to EBCDIC is done when needed, but might cause information loss. The field is filled in for SMF type 100, 101, and 102 if the standard header or optional correlation header section is present in the SMF record and the field contains non-blank, non-null information.

DB2_CONTEXT

This field contains the trusted context, which is a database security object. It can be used to establish a trust relationship between a DB2 database management system and an external entity, such as a middleware server. The default length of the field is 128, the maximum length 128. This field can be in UTF-8. You need an output file in UTF-8 encoding to be able to see all possible values. Conversion to EBCDIC is done when needed, but might cause information loss. The field is filled in for SMF type 100, 101, and 102 if the optional correlation header section is present in the SMF record and the field contains non-blank, non-null information. This is the case for most subtypes.

DB2_ENDUSER_USERID

This field contains the DB2 end-user userid as passed to DB2. It is only present for certain types of remote access. The default length of the field is 16, the maximum length is 128. This field is filled in for SMF type 100, 101, and 102 if the optional correlation header section is present in the SMF record and the field contains non-blank, non-null information.

DB2_OBJECT

This repeating field contains a DB2 object name. The object type is provided by field DB2_OBJECT_TYPE, with a few exceptions. For example, names of a different type can be reported with type UserAuth, but this is what the SMF record says). Object names are often constructed as two level names like "owner.table" or "database.space". The default length for this field is 128, the maximum length is 257. This field can be in UTF-8. You need an output file in UTF-8 encoding to be able to see all possible values. Conversion to EBCDIC is done when needed, but might cause information loss. This field is filled in for SMF type 102 subtypes/IFCids 6, 7, 8, 10, 22, 23, 24, 25, 62, 105, 107, 140, 142, 143, 144, 145, 177, 183, and 258, 271 if non-blank and non-null.

DB2_OBJECT_TYPE

This field contains the DB2 object type the event pertains to. Generally the object name is returned in field DB2_OBJECT, but there are some exceptions. For example, events pertaining to object type UserAuth are famous for containing object names of a different type. The default and maximum length of this field is 16. This field is filled in for SMF type 102 subtypes/IFCids 6, 7, 8, 10, 22, 23, 24, 25, 62, 105, 107, 140, 141, 142, 143, 144, 145, 177, 183, and 258, 271, 361, and 362.

DB2_ORIGINAL_OPERATOR

This field contains the DB2 Original Operator field. This is typically the userid submitting the work. If no real user can be identified, it is usually set to SYSOPR. The default length for this field is 8, the maximum length is 128. This field can be in UTF-8. You need an output file in UTF-8 encoding to be able to see all possible values. Conversion to EBCDIC is done when needed, but might cause information loss. This field is filled in for SMF type 100, 101, and 102 if the optional correlation header section is present in the SMF record and the field contains non-blank, non-null information.

DB2_PLAN

This field contains the DB2 plan name active when the event occurred. The default and maximum length for this field is 8. This field is filled in for SMF type 100, 101, and 102 if the optional correlation header section is present in the SMF record and the field contains non-blank, non-null information.

DB2_ROLE

The field contains a DB2 role name. The role groups one or more privileges. Roles can be assigned to a primary authorization ID or to PUBLIC. The role is available only in a trusted context. The default length of the field is 20, the maximum length 128. This field can be in UTF-8. You need an output file in UTF-8 encoding to be able to see all possible values. Conversion to EBCDIC is done when needed, but might cause information loss. The field is filled in for SMF type 100, 101, and 102 if the optional correlation header section is present in the SMF record and the field contains non-blank, non-null information. This is the case for most subtypes.

DB2_SECAUTHID

This repeating field contains DB2 secondary authids. One of these IDs might be equal to the GROUP field, but typically the GROUP field is only filled in for some DB2 SMF record subtypes on a DB2 8.1 or higher system where DB2 is configured with a SAF interface. Most RACF interface authorization exits use the RACF connect groups as DB2 secondary authids. The default length for this field is 8, the maximum length is 128. This field can be in UTF-8.You need an output file in UTF-8 encoding to be able to see all possible values. Conversion to EBCDIC is done when needed, but might cause information loss. This field is filled in for SMF type 102 subtype/IFCid 83 and 87 if non-blank and non-null.

DB2_SQLID

This repeating field contains DB2 SQL ids. If there are two, the first is the new and the second the old SQL id. The default length for this field is 8, the maximum length is 128. This field can be in UTF-8.You need an output file in UTF-8 encoding to be able to see all possible values. Conversion to EBCDIC is done when needed, but might cause information loss. This field is filled in for SMF type 102 subtype/IFCid 55, 83, and 87 if non-blank and non-null.

DESCRIPTOR, DESC

RACF descriptor. This field is found in RACF processing and R_auditx records (SMF record types 80 and 83). In addition, SUCCESS is emulated for job initiation and termination records (type 30), and WARNING is set for tape data set open and close records (type 14/15) in warning mode. This field is used to select records written for violations, warnings, undefined users, or successes. (Success is defined as the absence of a warning or violation.) When used for output, the default output is condensed; full output split into several lines can be requested using the EXPLODE output modifier and an overriding length of 15, for example, DESCRIPTOR(EXPLODE,15). Table 440 shows the DESCRIPTOR values and their meaning.

Security zSecure emulates successful LOGON and LOGOFF events by using JOB INITIATION and JOB TERMINATION records. See 1290 for more information. DESC is always SUCCESS for these events.

Table 440. SMF record DESCRIPTOR, DESC - values for output processing

SELECT/EXCLUDE	Output code	Exploded output	Meaning
SUCCESS SUCCESSES	S	Success	The event is a success
UNDEFINEDUSER UNDEFINED	U	Undefined user	User is not defined to RACF
FAILURE VIOLATION VIOL	V	Violation	The event is a violation

Table 440. SMF record DESCRIPTOR, DESC - values for output processing (continued)

SELECT/EXCLUDE	Output code	Exploded output	Meaning
WARNING WARN	W	Warning	The event is a warning

Note: For SELECT/EXCLUDE processing, only the =, <>, and ¬= relational operators can be used.

DSTIP

Destination IP address. This field is found in z/OS Firewall Technologies records, SMF record type 109, SMF record type 118 (IPv4), SMF record type 119 (IPv6) and in EIM auditing records (type 83 subtype 2) where it is extracted from the EIM domain name. In record types 109, 118 and 119 it always is an IP address, in the EIM records it will mostly be a hostname.

DSTPORT

Destination port number. This field is found in z/OS Firewall Technologies records, SMF record type 109, SMF record type 118 (IPv4), SMF record type 119 (IPv6) and in EIM auditing records (type 83 subtype 2) where it is extracted from the EIM domain name.

ELAPSED

This field indicates the amount of time it took to run the transaction in TOD-clock format. It is supported in CICS SMF 110 records and subrecords (SMF 110 subtype 1, subclass 3).

ESM

This field contains the name of the External Security Manager, if known, or the text SAF. This field is filled in correctly if the program could match the SMF data set to an allocated CKFREEZE and UNLOAD or live security data base.

EVENT

The EVENT field describes the RACF event code. This field is only found in RACF processing records (SMF record types 80 and 83). When used in SELECT and EXCLUDE processing, this field is used to select both events and event qualifiers. For output, these fields are separated in EVENT and EVENTQUAL, while the output-only field EVENTDESC can be used to print a description of both event and qualifier.

When used for output, the EVENT field prints a string. Use the overriding type NUM to get the numerical event code.

For SELECT and EXCLUDE processing, each event type can be selected by number or symbolic name (for example, the RACINIT event type is also referenced as event number 1).

Starting with z/OS 1.7, a single event number can have multiple symbolic names, depending on the SMF record type and subtype. For example, the number 1 is a RACINIT event in type 80 and type 83 subtype 1, but in type 83 subtype 2 it is an EIMCONN event. It is therefore faster, and usually more accurate, to select on the symbolic name instead of on the numeric value. Each event type can be further specified by a sublist of *event qualifiers*. Event qualifiers are specified in a sublist, where a range of qualifiers can be specified using a colon (a range of events is not supported). Event qualifiers can also be specified using the symbolic values ALLOWED, SUCCESS, WARNING and FAILURE.

The following examples illustrate the syntax of the EVENT field.

Note: Only the =, <>, and ¬= relational operators can be used in SELECT and EXCLUDE statements.

```
SELECT EVENT=(PASSWORD, PERMIT, ADDSD)
SELECT EVENT=(RACINIT(1, 2, 3, 4, 5), RENAME(1))
SELECT EVENT=ALLCOMMAND(FAILURE)
SELECT EVENT=(APPCLU(FAILURE), 45(0, 1, 2), RACINIT(1:5, 8, 9))
SELECT EVENT<>(RACINIT(FAILURE) PASSWORD(ALLOWED))
```

Because RACF does not write SMF records for successful LOGON and LOGOFF events, Security zSecure emulates them from JOB INITIATION and JOB TERMINATION records (SMF type 30, subtypes 1 and 5). This emulation allows you to select and view all RACF LOGON and RACF LOGOFF events simply by selecting on RACINIT events.

The following sections provide reference information for the different types of event codes available for use in the SELECT and EXCLUDE statements.

- 1291
- 1291
- 1292
- 1293
- 1295

Symbolic event codes

In addition to the individual event codes defined in the following table, three symbolic *combination* event codes are defined:

Table 441. SMF record EVENT field - event code descriptions

Event code	Event type	Event numbers
ALLSVC	All RACF SVC events	1 through 7
ALLCOMMAND ALLCMD ALLCMDS ALLCOMMANDS	All RACF commands	8 through 25, 59, 66 and 78
ALLOMVS	All OpenEdition MVS events	28 through 58, 60 through 65, 75 through 77

Symbolic event qualifiers

The meaning of the symbolic event qualifiers is defined in the following table.

Table 442. SMF record EVENT field - symbolic event code descriptions

Symbolic qualifier	Meaning
ALLOWED	Successful and warning events: an action that succeeded
FAILURE VIOLATION	Failure event: the event did not succeed, but was a violation
SUCCESS	Success event: an action that succeeded without a warning
WARNING	Warning event: the event succeeded, but generated a warning

IBM Tivoli Key Lifecycle Manager event code descriptions

Table 443 lists the predefined Tivoli Key Lifecycle Manager event code (SMF record types 83, subtype 6) supported by Security zSecure. The first two columns list the events sorted by name. The second two columns show the same events sorted by event code. The event qualifier and descriptor text for these events are derived from the text in the SMF record.

Table 443. SMF record EVENT field - Tivoli Key Lifecycle Manager event code descriptions

Event Name	Event Code	Event Code	Event Name
TKLMAUTN	2	1	Unknown
TKLMAUTT	3	2	TLKMAUTN
TKLMAUTZ	4	3	TLKMAUTT
TKLMAUDI	6	4	TKLMAUTZ
TLKMCONF	7	5	TKLMSYNC
TKLMKEYR	8	6	TKLMAUDI
TKLMRESM	9	7	TLKMCONF
TKLMRUNT	10	8	TKLMKEYR
TKLMSYNC	5	9	TKLMRESM
UNKNOWN	1	10	TKLMRUNT

Predefined RACF and R_auditx event codes

Table 444 describes the predefined RACF and R_auditx event codes (SMF record types 80 and 83) supported by Security zSecure. The first two columns list the events sorted by name. The second two columns show the same events sorted by event code. For information on the event qualifiers for these event codes, see 1295.

Note: All event codes can also be selected by numerical value. The numerical values can also be used to select events that have not been predefined. This selection method can be useful when new event codes are introduced but are not yet supported by Security zSecure.

Table 444. SMF record EVENT field - predefined RACF and R_auditx event code descriptions

Name	Event code	Event code	Name
ACCESS	2	1	RACINIT
ADDGROUP	9	2	ACCESS
ADDSD	8	3	ADDVOL
ADDUSER	10	4	RENAME
ADDVOL	3	5	DELETE
ALTDSD	11	6	DELVOL
ALTGROUP	12	7	DEFINE
ALTUSER	13	8	ADDSD
APPCLU	26	9	ADDGROUP
CONNECT	14	10	ADDUSER
DEFINE	7	11	ALTDSD
DELDSD	15	12	ALTGROUP
DELETE	5	13	ALTUSER

Table 444. SMF record EVENT field - predefined RACF and R_auditx event code descriptions (continued)

Name	Event code	Event code	Name
DELGROUP	16	14	CONNECT
DELVOL	6	15	DELDSD
DELUSER	17	16	DELGROUP
GENERAL	27	17	DELUSER
initACEE	67	18	PASSWORD/PHRASE The PHRASE command is an alias of the PASSWORD command. These two commands are indistinguishable from each other in SMF. You can use SELECT EVENT=PHRASE as an alternative to SELECT EVENT=PASSWORD.
KTICKET	68	19	PERMIT
PASSWORD/ PHRASE	18	20	RALTER
PDACCESS	71	21	RDEFINE
PERMIT	19	22	RDELETE
PKIDPUBR	79	23	REMOVE
PTCREATE	82	24	SETROPTS
PTEVAL	81	25	RVARY
RACDCERT	66	26	APPCLU
RACINIT	1	27	GENERAL
RACLINK	59	59	RACLINK
RACPRIV	78	66	RACDCERT
RALTER	20	67	initACEE
RDEFINE	21	68	KTICKET
RDELETE	22	69	RPKIGENC
REMOVE	23	70	RPKIEXPT
RENAME	4	71	PDACCESS
RPKIEXPT	70	72	RPKIREAD
RPKIGENC	69	73	RPKIUPDR
RPKIREAD	72	74	RPKIUPDC
RPKIRESP	80	78	RACPRIV
RPKIUPDC	74	79	PKIDPUBR
RPKIUPDR	73	80	RPKIRESP
RVARY	25	81	PTEVAL
SETROPTS	24	82	PTCREATE

OpenEdition MVS event codes

Table 445 on page 1294 list the OpenEdition MVS event types supported by zSecure. The events are listed in ascending order by event code.

Table 445. SMF record EVENT field - OpenEdition MVS event code descriptions

Event code	Name
28	DIRSRCH
29	DACCESS
30	FACCESS
31	CHAUDIT
32	CHDIR
33	CHMOD
34	CHOWN
35	CLRSETID
36	EXESETID
37	GETPSENT
38	INITOEDP
39	TERMOEDP
40	KILL
41	LINK
42	MKDIR
43	MKNOD
44	MNTFSYS
45	OPENFILE
46	PTRACE
47	RENAMEF
48	RMDIR
49	SETEGID
50	SETEUID
51	SETGID
52	SETUID
53	SYMLINK
54	UNLINK
55	UMNTFSYS
56	CHKFOWN
57	CHKPRIV
58	OPENSTTY
60	CHK_IPC
61	MAKE_ISP
62	R_IPCntl
63	SETGRPS
64	CHKF2OWN
65	R_AUDIT
75	SETFACL
76	DELFACL
77	SETFSECL

Numerical event code qualifiers

The following tables list the numerical event qualifiers.

See the IBM publication *Security Server RACF Macros and Interfaces (SA22-7682)* for information on the numerical `eventqualifiers` that exist on your system for SMF record types 80 and 83.

Note: If IBM adds new event qualifiers not in these tables, Security zSecure handles them properly. Remember that symbolic qualifiers (FAILURE, WARNING, SUCCESS can also be used, and are usually preferable.

The following tables provide event qualifier information for the SMF record type 80 and 83 events.

Table 446. Event 1 qualifier codes and descriptions

Qualifier	Meaning
0	Successful start of job
1	Invalid password specified
2	The user is not a member of the used group
3	An invalid OIDCARD was used
4	The user is not authorized to the Port Of Entry
5	The user is not allowed to log on to the application specified
6	Access attempt by a revoked user
7	The RACINIT has automatically revoked the user because of excessive password and pass phrase attempts
8	Successful end of job
9	The userid specified is undefined
10	Insufficient SECLABEL authority
11	The user is not authorized to the SECLABEL specified
12	Successful verification of job or logon
13	End of job, or logoff
14	SETROPTS MLQUIET: user or job not allowed, system now requires more authority
15	RJE job not authorized
16	Surrogate job specified, but SURROGAT class not active
17	Surrogate job specified, and user not authorized to job
18	Surrogate job specified, and user not authorized to SECLABEL
19	User not authorized to job by JESJOBS class
20	Warning: insufficient SECLABEL authority
21	Warning: no SECLABEL specified

Table 446. Event 1 qualifier codes and descriptions (continued)

Qualifier	Meaning
22	Warning: the user is not authorized to the SECLABEL specified
23	The SECLABELS specified are not compatible
24	Warning: the SECLABELS specified are not compatible
25	The user's current password has expired
26	Invalid new password specified
27	Verification failed by installation exit ICHRIX01
28	Access attempt to revoked group-connect
29	An OIDCARD is required, but none was given
30	NJE job not authorized
31	Warning: unknown user propagated from trusted node
32	Successful logon using a PassTicket
33	Attempted logon using a replay of a PassTicket failed
34	Client `SECLABEL` not equivalent to servers
35	Userid automatically revoked due to inactivity
36	Invalid password phrase
37	Invalid new password phrase
38	Current password phrase has expired

Table 447. Event 2 qualifier codes and descriptions

Qualifier	Meaning
0	Successful access
1	Insufficient authority
2	Discrete profile not found
3	Warning: access only permitted because of warning mode on the profile
4	Access failed due to PROTECTALL
5	Warning: access only permitted because PROTECTALL was used in warning mode
6	Insufficient SECLEVEL or CATEGORY
7	Insufficient SECLABEL authority
8	Warning: SECLABEL required but not specified
9	Warning: Insufficient SECLABEL authority
10	Warning: Data set not cataloged
11	Data set not cataloged
12	Profile not found, resource class has RC>4.
13	Warning: Insufficient SECLEVEL or CATEGORY
14	Warning: no MAIN mode execution environment was present when using conditional access or an EXECUTE controlled program. Access granted due to ENHANCED-WARNING PGMSECURITY mode
15	A BASIC mode program used conditional access or an EXECUTE controlled program in ENHANCED PGMSECURITY mode

Table 448. Event 3 ADDVOL: Add and change volume qualifier codes and descriptions

Qualifier	Meaning
0	Successful processing of new volume
1	Insufficient authority to the profile
2	Insufficient SECLABEL authority
3	SETROPTS MLSTABLE: a less specific profile exists with a different SECLABEL

Table 449. Event 4: RENAME qualifier codes and descriptions

Qualifier	Meaning
0	Successful rename
1	Invalid HLQ specified for data set (not a user or group)
2	Data set renamed to a group data set, and user not in group
3	Insufficient authority
4	The discrete profile already exists
5	The naming convention exit has refused the userid
6	SETROPTS PROTECTALL: resource not protected
7	Warning: SETROPTS PROTECTALL: resource not protected
8	The second qualifier is not a userid
9	SETROPTS MLSTABLE: a less specific profile exists with a different SECLABEL
10	SETROPTS MLS: Insufficient SECLABEL authority
11	SETROPTS MLS: Old profile not protected by SECLABEL
12	SETROPTS MLS: New profile not protected by SECLABEL
13	SETROPTS MLS: New profile does not dominate old profile
14	Warning: SETROPTS MLS: Insufficient SECLABEL authority
15	Warning: SETROPTS MLS: Old profile not protected by SECLABEL
16	Warning: SETROPTS MLS: New profile not protected by SECLABEL
17	Warning: SETROPTS MLS: New profile does not dominate old profile

Table 450. Event 5: DELETE qualifier codes and descriptions

Qualifier	Meaning
0	Successful deletion of profile
1	Profile not found
Qualifier	Meaning
0	Successful deletion of volume
2	Invalid volume specified

Table 451. Event 6: DELVOL (delete one volume) qualifier codes and descriptions

Qualifer	Meaning
0	Successful deletion of volume.

Table 452. Event 7 DEFINE: Define resource qualifier codes and descriptions

Qualifier	Meaning
0	Successful definition of profile
1	Invalid HLQ specified for data set (not a user or group)
2	Data set renamed to a group data set, and user not in group
3	Insufficient authority
4	The discrete profile already exists
5	The naming convention exit has refused the userid
6	SETROPTS PROTECTALL: resource not protected
7	Warning: SETROPTS PROTECTALL: resource not protected
8	Warning: SETROPTS MLACTIVE: No SECLABEL specified
9	Warning: SETROPTS MLS: Insufficient SECLABEL authority
10	The second qualifier is not a userid
11	Insufficient SECLABEL authority
12	SETROPTS MLSTABLE: a less specific profile exists with a different SECLABEL

Table 453. ALLCMDS Events 8 - 25, 59, 78 qualifier codes and descriptions

Qualifier	Meaning
0	No violations detected
1	Insufficient authority to issue RACF command
2	Authority to issue RACF command, but keyword violations detected (partial update of the RACF database)
3	Successful retrieval of data set names affected by a security label change (only for DATASET commands)
4	System error retrieving data set names affected by a security label change (only for DATASET commands)

Table 454. Event 26 APPCLU: APPC session establishment qualifier codes and descriptions

Qualifier	Meaning
0	Successful session verification
1	Session established without verification
2	Local LU key will expire within 5 days
3	The partner LU access has been revoked, too many session key attempts failed
4	Partner LU key does not match local LU key
5	Session terminated because of LOCK keyword
6	Session key required but not defined
7	Possible security attack by partner LU
8	No session key defined for partner LU
9	No session key defined for local LU
10	SNA protocol error
11	Profile changed during verification
12	Local or partner session key has expired

Table 455. Event 27 General (application defined event): qualifier codes and descriptions

Qualifier	Meaning
0-99	Application-defined qualifier

Table 456. Events 28 – 30, 32 –37, 39 – 58, 60, 61 – 65, 75 – 77: ALLOMVS qualifier codes and descriptions

Qualifier	Meaning
0	No violations detected
1	Caller is not authorized to perform function
2	Security label failure

Table 457. Event 31: CHAUDIT qualifier codes and descriptions

Qualifier	Meaning
0	File's audit options changed
1	Caller does not have authority to change user audit options for this file
2	Caller does not have authority to change auditor audit options for this file
3	Security label failure

Table 458. Event 38 (INITOEDP (initialize z/OS UNIX process) qualifier codes and descriptions

Qualifier	Meaning
0	z/OS UNIX process successfully initialized
1	The user is not defined as UNIX user (no userid or no OMVS segment)
2	The user does not have a UID
3	The user's current connect group does not have a GID

Table 459. Event 59: Remote Sharing Facility RACLINK event qualifier codes and descriptions

Qualifier	Meaning
0	No violations detected
1	Insufficient authority to issue RACF command
2	Authority to issue RACF command, but keyword violations detected
3	Association was already defined
4	Association has already been approved
5	Association does not match
6	Association does not exist
7	No authorization to userid
8	Invalid password

Table 460. Event 61: MAKE_ISP qualifier codes and descriptions

Qualifier	Meaning
0	Successful creation of ISP

Table 460. Event 61: MAKE_ISP qualifier codes and descriptions (continued)

Qualifier	Meaning
1	Security label failure

Table 461. Event 67: INITACEE (certificate registration) qualifier codes and descriptions

Qualifier	Meaning
0	Successful certificate registration
1	Successful certificate deregistration
2	Caller is not authorized to register the certificate
3	Caller is not authorized to deregister the certificate
4	No user ID found for the certificate
5	The certificate is not trusted
6	Successful certificate authority certificate registration
7	Caller is not authorized to register the certificate authority certificate
8	The client SECLABEL is not equivalent to that of the server

Table 462. Event 68: KTICKET (Initial grant of Kerberos ticket) qualifier codes and descriptions

Qualifier	Meaning
0	Successful grant of Kerberos ticket
1	Failure to grant Kerberos ticket

Table 463. SMF record EVENT field - Event 69 qualifier codes and descriptions

Qualifier	Meaning
0	Successful certificate generation
1	Caller has insufficient authority to generate the certificate
2	Successful certificate generation request
3	Caller has insufficient authority to request generation of the certificate
4	Successful certificate renewal
5	Caller has insufficient authority to renew the certificate
6	Successful certificate renewal request
7	Caller has insufficient authority to request renewal of the certificate
8	Successful user preregistration
9	Caller has insufficient authority to preregister the user

Table 464. Event 70: RPKIEXPT (R_PKIServ EXPORT) qualifier codes and descriptions

Qualifier	Meaning
0	Successful certificate export
1	Caller has insufficient authority to export the certificate
2	Incorrect pass phrase specified

Table 465. Event 71: PDACCESS (Policy director access control decision) qualifier codes and descriptions

Qualifier	Meaning
0	Authorized to access object
1	Warning: Caller has insufficient authority to the object
2	Warning: Caller has insufficient traverse authority
3	Warning: Caller is not authorized due to a time-of-day check
4	Caller has insufficient authority to the object
5	Caller has insufficient traverse authority
6	Caller is not authorized due to a time-of-day check

Table 466. SMF record EVENT field - Event 72 qualifier codes and descriptions

Qualifier	Meaning
0	Successful admin QUERY or DETAILS request
1	Caller has insufficient authority for the admin QUERY or DETAILS request
2	Successful VERIFY request
3	Caller has insufficient authority for the VERIFY request
4	No record was found for the certificate in the VERIFY request

Table 467. Event 73: RPKIUPDR (R_PKIServUPDATEREQ) qualifier codes and descriptions

Qualifier	Meaning
0	Successful admin UPDATEREQ request
1	Caller has insufficient authority for the admin UPDATEREQ request

Table 468. SMF record EVENT field - Event 74 qualifier codes and descriptions

Qualifier	Meaning
0	Successful admin UPDATECERT request
1	Caller has insufficient authority for the admin UPDATECERT request
2	Successful REVOKE request
3	Caller has insufficient authority for the REVOKE request

Table 469. Event 79: PKIDPUBR (CRL publication) qualifier codes and descriptions

Qualifier	Meaning
0	Successful publication of Certificate Revocation List

Table 470. Event 80: RPKIRESP (R_PKIServRESPOND) qualifier codes and descriptions

Qualifier	Meaning
0	Successful RESPOND request
1	Caller has insufficient authority for the RESPOND request

Table 471. Event 81: PTEVAL (Passticket evaluation) qualifier codes and descriptions

Qualifier	Meaning
0	Successful passticket evaluation
1	Failure during passticket evaluation

Table 472. Event 82: PTECREATE (Passticket generation) qualifier codes and descriptions

Qualifier	Meaning
0	Successful passticket generation
1	Failure during passticket generation

Table 473. Event 83: RPKISCEP (R_PKIServSCEPREQ) qualifier codes and descriptions

Qualifier	Meaning
0	Successful AutoApprove PKCSReq request
1	Successful AdminApprove PKCSReq request
2	Successful GetCertInitial request
3	Rejected PKCSReq or CetCertInitial request
4	Incorrect SCEP transaction ID specified for GetCertInitial request
5	Caller has insufficient authority to issue a SCEPREQ request

Events defined for Event 83, subtype 2: EIM auditing

Table 474 lists the event codes for EIM auditing records. Each EIM event listed has a qualifier variable that returns event information. To see the possible values returned, see the table associated with each qualifier.

Table 474. Event 83, subtype 2: Events defined for EIM auditing (Record type 83 subtype 2) qualifier codes and descriptions

Event code	Event qualifier
1	EIMCONN (See Table 475.)
2	EIMLKUP (See Table 476 on page 1304.)
3	EIMSETUP (See Table 477 on page 1304.)
4	EIMADMIN (See Table 478 on page 1304.)

Complete information on the numerical event qualifiers that exist on your system for the different event types can be found in the Auditing chapter in the IBM publication *Integrated Security Services Enterprise Identity Mapping (EIM) Guide and Reference*.

Table 475. Event 1: EIM Connection Event - qualifier codes and description

Qualifier	Meaning
0	Successful connect to the domain controller or a disconnection from the domain controller
3	Not authorized to connect to the domain controller

Table 476. Event 2 - EIM Lookup qualifier codes and descriptions

Qualifier	Meaning
0	Successful request
1	Insufficient authority to request EIM data
2	Mapping not found or the user was not authorized to access the EIM data

Table 477. Event 3: EIM Administrative Setup event - Domain, Registry, Access qualifier codes and descriptions

Qualifier	Meaning
0	Successful request
1	Unable to connect to the EIM domain
3	Insufficient authority to modify the EIM domain or retrieve information from the domain

Table 478. Event 4 - EIM Administrative - Identifiers, Associations, Policies qualifier codes and descriptions

Qualifier	Meaning
0	Successful request
1	Insufficient authority to modify the EIM domain or retrieve information from the domain

LDAP auditing records

The following tables lists the event codes for LDAP events recorded in the SMF data set. Each LDAP event listed has a unique event code with a corresponding event code qualifier variable that returns event information.

Table 479. SMF record, event 83, subtype 3: LDAP events

Event and meaning	Qualifier and meaning
1 - ADD operation	0 (Success), 1 (Failure)
2 - BIND operation	0 (Success), 1 (Failure)
3 - COMPARE operation	0 (Success), 1 (Failure)
4 - CONNECT operation	0 (Success), 1 (Failure)
5 - DELETE operation	0 (Success), 1 (Failure)
6 - DISCONNECT operation	0 (Success), 1 (Failure)
7 - EXTENDED operation	0 (Success), 1 (Failure)
8 - MODIFY operation	0 (Success), 1 (Failure)
9 - MODIFYDN operation	0 (Success), 1 (Failure)
10 - SEARCH operation	0 (Success), 1 (Failure)
11 - UNBIND operation	0 (Success), 1 (Failure)

Table 480. SMF record, event 83, subtype 4: R_AUDIT events

Event and meaning	Qualifier and meaning
1 - Authentication	0 (Success), 1 (Info), 2 (Warning), 3 (Failure)
2 - Authorization	0 (Success), 1 (Info), 2 (Warning), 3 (Failure)

Table 480. SMF record, event 83, subtype 4: R_AUDIT events (continued)

Event and meaning	Qualifier and meaning
3 - Auth mapping	0 (Success), 1 (Info), 2 (Warning), 3 (Failure)
4 - Key management	0 (Success), 1 (Info), 2 (Warning), 3 (Failure)
5 - Policy management	0 (Success), 1 (Info), 2 (Warning), 3 (Failure)
6 - Admin config	0 (Success), 1 (Info), 2 (Warning), 3 (Failure)
7 - Admin action	0 (Success), 1 (Info), 2 (Warning), 3 (Failure)

Signature verification auditing records

The following tables lists the event codes for signature verification auditing records. Each signature verification event listed has a qualifier variable that returns event information. To see the possible values returned, see the table associated with each qualifier.

Table 481. SMF record, event 86 (PSIGVER) signature verification qualifier codes and descriptions

Qualifier	Meaning
00	Successful signature verification.
01	Signature appears valid but root CA certificate not trusted.
02	Module signature failed verification.
03	Module certification chain incorrect.
04	Signature required by module not signed.
05	Signature required but signature has been removed.

EVENT_DATETIME

The EVENT_DATETIME field indicates the date and time of the transaction start. It has the same value as the DATETIME field. This field is only supported on CICS monitoring performance class subrecords (SMF subtype 1, subclass 3), The date is reported in local time.

EVENT_DATETIME_SMF

The EVENT_DATETIME field indicates the date and time of the transaction start. It has the same value as the DATETIME field. This field is only supported on CICS monitoring performance class subrecords (SMF subtype 1, subclass 3), The date is reported in local time.

EVENTDESC

The EVENTDESC field can only be used for output. It is found in the following records:

- Tivoli Key Lifecycle Manager audit security records (SMF record types 83, subtype 6)
- RACF processing and R_auditx records (SMF record types 80 and 83)

For Tivoli Key Lifecycle Manager audit security records, the event qualifier and descriptor text are derived from the text in the SMF record.

For RACF and R_auditx records, the field contains the name of the event, an indication of the result and a short explanation of the event qualifier, *Invalid password* for example.

The result field can be:

- **Success**
- **Warning**
- **Failure**
- **Undefined**

To print the numerical event qualifier, use the EVENTQUAL output field.

The default output length of this field is 64 characters. The full length can be up to 68 characters.

Note: The values printed by the EVENTDESC field are subject to change. Therefore, do not write applications that are dependent on the output of this field.

Security zSecure emulates successful LOGON and LOGOFF events by using JOB INITIATION and JOB TERMINATION records. See 1290 for more information.

EVENTQUAL

The EVENTQUAL field can only be used for output and is only found in RACF processing and R_auditx records (SMF record types 80 and 83). It can be used to print a numerical event qualifier. To print the event code, use the EVENT field described above; to print a description of the event and event qualifier, use the EVENTDESC field described above. To select records on event qualifier, use the EVENT field. The available event qualifiers are also listed with the EVENT field.

Security zSecure emulates successful LOGON and LOGOFF events by using JOB INITIATION and JOB TERMINATION records. See 1290 for more information. The event qualifiers are 0 and 8 for JOB INITIATION and JOB TERMINATION, respectively.

EXPLANATION

This field provides an additional description of a record and might indicate the cause of the record's creation. The field is only found in z/OS Firewall Technologies records (SMF record type 109) with message identifiers (MSGID) ICA1005e, ICA1032i, ICA1033i, ICA1034i, and ICA1035i.

FIELDVAL

This field can only be used for SELECT/EXCLUDE processing and is primarily meant for debugging purposes. It can also be used to select records by criteria not provided for by Security zSecure. FIELDVAL is used to select records that have specific values set at a specific offset. No equivalent output field exists.

The FIELDVAL field has the following syntax:
FIELDVAL=(offset in record,type,value) or
FIELDVAL=(offset in record,type,(list-of-values)). Both the offset and the values are in decimal; offset 0 indicates the start of the record (the length field). No relational operators other than = are allowed.

The following table describes the types supported:

Table 482. SMF FIELDVAL field - record types, descriptions and values

Type	Meaning	Values
BYTE	1-byte value	single or list
HALF	2-byte value	single or list
FULL	4-byte value	single or list

Table 482. SMF FIELDVAL field - record types, descriptions and values (continued)

Type	Meaning	Values
MASK1	1-byte bit mask (compare operation; the record is selected if any bit is set both in the record and in the bit mask)	single
MASK2	2-byte bit mask (compare operation; the record is selected if any bit is set both in the record and in the bit mask)	single

FILE

This field describes a ddname used by a program. It can be found in data set and activity records (SMF record types 14, 15, and 64), and ACF2 data set use records. These records also have a DATASET field; when both are used, the correspondence between ddname and data set name can be found.

GROUP

Group id. This field is found in the following record types:

- CICS monitoring records (SMF record type 110, subtype 1)
- For data set and ICF catalog activity records, it is derived using the job tag system (These records are SMF record types 14, 15, 17, 18, 60, 61, 62, 64, 65 and 66).
- CSSMTP client records (SMF record type 119) with subtype 48 if non-blank and non-null
- DB2 records (SMF record type 102) with subtypes/IFCids 83, 87, 140, 142, 269, and 314 if non-blank and non-null.
- DFSORT records (SMF record type 16)
- Job Initiation and Accounting records (SMF record types 20, 30 and 32)
- HSM function statistics records
- RACF processing and R_auditx records (SMF record types 80 and 83)
- NFS audit statistics records (SMF record type 42, subtype 26)

To select a group id that is the target of a RACF command, use one of the RACFCMD_GROUP, RESOURCE or PROFILE fields instead. The GROUP field describes the current connect group of the RACF command-issuing user, not the target group.

HOSTNAME

TCP/IP host name. This field is only found in z/OS Firewall Technologies records (SMF record type 109).

INTENT

SAF intended access. This field is found in RACF processing records (SMF record types 80 and 83 subtype 1) written for a RACHECK (EVENT=ACCESS). Also, it is derived for data set or ICF catalog activity records, as shown in the following table.

Table 483. SMF INTENT field - SMF type, Subtype and descriptions

SMF Type	Subtype	Description	INTENT derived
14		INPUT or RDBACK Data Set Activity	READ
15		OUTPUT, UPDATE, INOUT or OUTIN Data Set Activity	UPDATE
17		Scratch Data Set Status	ALTER
18		Rename Data Set Status	ALTER
42	26	NFS audit statistics	ALTER
61		ICF Define Activity	ALTER
62		VSAM Component or cluster open	READ, UPDATE, or CONTROL (action-dependent)
64		VSAM Component or Cluster Status	READ, UPDATE, or CONTROL (action-dependent)
65		ICF Delete Activity	ALTER
66		ICF Alter Activity	ALTER
102	6, 7, 34, 35, 114, 115, 116, 117, 118, 144	DB2 audit reads	READ
	8, 9, 10, 32, 38, 39, 40, 41, 119, 120, 143, 258	DB2 audit writes	UPDATE
	62, 142	DB2 audit alters	ALTER
	140, 145, 220	DB2 audit	NONE, EXECUTE, READ, UPDATE, or ALTER Action dependent

Possible INTENT values are documented in the following table (increasing sort order).

Table 484. SMF INTENT field - possible values

INTENT value
NONE
EXECUTE
READ
UPDATE
CONTROL
ALTER
OWNER

Access granted through the global access table will not show for record type 8x, but will be available through the other types.

IP_AUTOLOG_JOBNAME

A Repeat group field. The IP_AUTOLOG_JOBNAME field contains the name of the job used for the PORT reservation statement. This value can be identical to the value in the IP_AUTOLOG_PROCNAME field, but for z/OS UNIX jobs that create listener threads, it is not. If IP_AUTOLOG_JOBNAME is missing, the job name is assumed to be the same as the value of the IP_AUTOLOG_PROCNAME field.

IP_AUTOLOG_OPTIONS

The IP_AUTOLOG_OPTIONS repeat group flag field provides information about the following IP autolog configuration settings.

DELAYSTART DVIPA
The AUTOLOG procedure starts after the TCP/IP stack has joined the sysplex group and has processed its dynamic VIPA configuration.

DELAYSTART TTLS
The AUTOLOG procedure starts after the Policy Agent has successfully installed the AT-TLS policy in the TCP/IP stack and AT-TLS services are available.

IP_AUTOLOG_PARMSTRING

A Repeat group field. The IP_AUTOLOG_PARMSTRING field provides the parameter string to be added following the `START procedure_name`, where *procedure_name* is the value is found in the IP_AUTOLOG_PROCNAME field.

IP_AUTOLOG_PROCNAME

A Repeat group field. The IP_AUTOLOG_PROCNAME field contains the name of a procedure that the TCP/IP address space should start.

IP_AUTOLOG_WAIT

A Repeat group field. The IP_AUTOLOG_WAIT field shows the number of minutes that TCP/IP should allow for a procedure to come down when, at startup, it is still active and TCP/IP is attempting to AUTOLOG the procedure again. This could happen if the procedure did not come down when TCP/IP was last shutdown. When the IP_AUTOLOG_WAIT value is 0, TCP/IP startup does not cancel and restart any procedures in the autolog list that are already started. TCP/IP does not cancel the procedure at initialization. TCP/IP checks every 10 seconds (until the time interval specified by wait has expired) to check if the procedure has come down. If the procedure comes down during one of these 10 second intervals, it is restarted. If the procedure is still active when the time interval specified by wait expires, then TCP/IP cancels and restarts the procedure.

IP_CONFIG_CHANGES

IP_CONFIG_CHANGES is a repeated flag field that provides detailed information about IP configuration changes. Table 485 lists the fields that can be included in the IP_CONFIG_CHANGES field.

Table 485. IP_CONFIG_CHANGES field descriptions

Field	Description
DEP_INTERFACE	DEVICE, LINK, or BSDROUTINGPARMS statements were specified for non-strategic interface types.
DEP_HOME	HOME statements were specified for non-strategic interface types.
DEP_BEGINROUTES	GATEWAY or BEGINROUTES statements were used for non-strategic interface types.

Table 485. IP_CONFIG_CHANGES field descriptions (continued)

Field	Description
DEP_SMFCONFIG	Deprecated SMF statements, SMFPARMS, or SMFCONFIG 118 statements were specified.
DEP_TRANSLATE	TRANSLATE statements were specified for non-strategic interface types.
DEP_VIPASMPARMS	Deprecated
VIPADYNAMIC	VIPASMPARMS statements were specified.
CHANGED_AUTOLOG	An Autolog Procedure section was changed.
CHANGED_DV_ROUTES	A DVIPA Routes section was changed.
CHANGED_DIST_DV	A Distributed DVIPA section was changed.
CHANGED_IPV4	An IPv4 Configuration section was changed.
CHANGED_IPV6	An IPv6 Configuration section was changed.
CHANGED_TCP	A TCP Configuration section was changed.
CHANGED_UDP	An UDP Configuration section was changed.
CHANGED_GLOBAL	A Global Configuration section was changed.
CHANGED_PORT	A Port section was changed.
CHANGED_INTERFACE	An Interface / IPv4 addresses section was changed.
CHANGED_IPA6	An IPv6 addresses section was changed.
CHANGED_ROUTE	A Routes section was changed.
CHANGED_SRCIP	A Source IP section was changed.
CHANGED_MGMT	A Management section was changed.
CHANGED_IPSECCM	An IPSec Common section was changed.
CHANGED_IPSECRULE	An IPSec Default Rules section was changed.
CHANGED_NETACC	A Network Access section was changed.
CHANGED_DVIPA	A Dynamic VIPA (Virtual IP Address) Addresses section was changed.

IP_DATETIME_STARTED

The IP_DATETIME_STARTED field provides the date and time that the TCP/IP stack was started. The format of this field is DATETIME.

IP_DSNMEM

A Repeat group field. The IP_DSNMEM field contains a profile information entry for each data set name followed by a member name between brackets ([membername]). The data set name entries can originate from the following sources: an OBEYFILE command, the default library found in the standard search sequence, or an INCLUDE statement.

IP_DYNAMICXCF_INTFID

The IP_DYNAMICXCF_INTFID field specifies the interface ID which is used to form the link-local address for the interface. If this field is missing, TCP/IP generates a random value to be used to form the link-local address. The field value can be changed through the use of IPCONFIG6 statements.

IP_DYNAMICXCF_IP

The IP_DYNAMICXCF_IP field contains the IP address to be used as the home address for all dynamically generated XCF, Same Host, and HiperSockets links. The field value can be changed through the use of IPCONFIG statements.

IP_DYNAMICXCF_IPMASK

The IP_DYNAMICXCF_IPMASK field specifies the interface-level subnet mask for the IP_DYNAMICXCF link. If using OMPROUTE, this value is overridden with a corresponding OMPROUTE interface parameter value that can be coded or set to the default value. The field value can be changed through the use of IPCONFIG statements. If the destination address is IPv6, the IP_DYNAMICXCF_IPMASK field will be missing.

IP_DYNAMICXCF_IP6

The IP_DYNAMICXCF_IP6 field specifies the fully qualified IPv6 address that is used for all dynamically generated XCF, Same Host, and HiperSockets interfaces. The field value can be changed through the use of IPCONFIG6 statements.

IP_DYNAMICXCF_PFXLEN

The IP_DYNAMICXCF_PFXLEN field specifies the number of leftmost significant bits for the address mask. The field value can be changed through the use of IPCONFIG statements.

IP_DYNAMICXCF_PFXLEN6

The IP_DYNAMICXCF_PFXLEN6 field specifies the length of the routing prefix. If this field is not missing and if IP_DYNAMICXCF generates a HiperSockets interface definition, TCP/IP creates a prefix route over the HiperSockets interface using the number of bits specified in IP_DYNAMICXCF_PFXLEN6 of the IP_DYNAMICXCF_ADDRESS6. Therefore, you can configure other stacks outside the sysplex for the same IQD CHPID using IP addresses with the same prefix. This configuration automatically provides this stack with a route to the other stacks over the HiperSockets interface generated by IP_DYNAMICXCF. If IP_DYNAMICXCF_PFXLEN6 is missing, then TCP/IP does not create a prefix route over the HiperSockets interface. For interfaces other than HiperSockets which are generated from IP_DYNAMICXCF, the IP_DYNAMICXCF_PFXLEN6 value has no meaning. The field value can be changed through the use of IPCONFIG6 statements.

IP_DYNAMICXCF_SECCLASS

The IP_DYNAMICXCF_SECCLASS field specifies the security class for IP filtering associated with each dynamic XCF interface. In order for traffic over the interface to match a filter rule, the filter rule must have the same security class value as the interface or a value of 0. The value is used only when IPSECURITY is one of the values of the IPCONFIG field. Valid security classes are integers in the range 1 - 255. The default value is 255. The field value can be changed through the use of IPCONFIG statements.

IP_DYNAMICXCF_SECCLASS6

The IP_DYNAMICXCF_SECCLASS6 field specifies the security class for IP filtering with each IPv6 dynamic XCF interface. In order for traffic over the interface to match a filter rule, the filter rule must have the same security class value as the interface or a value of 0. The value is used only when IPSECURITY is one of the values of the IPCONFIG6 field. Valid security classes are integers in the range 1 - 255. The default value is 255. The field value can be changed through the use of IPCONFIG6 statements.

IP_DYN_XCF_SOURCEVIPAINT

The IP_DYN_XCF_SOURCEVIPAINT field specifies the name of the static VIPA interface used as the source IP address when SOURCEVIPA is one of the IPCONFIG6 values and outbound packets are sent over the dynamically generated XCF or Same Host interfaces.

IP_GLOBALCONF_IQDVLAN

The IP_GLOBALCONF_IQDVLAN field returns the VLAN ID which is used when HiperSockets (iQDIO) connectivity is used for dynamic XCF support. Valid VLAN IDs are integers in the range 1 - 4094. VLAN IDs are used to partition communication across HiperSockets. Stacks on the same CPC using the same HiperSockets CHPID that use the same VLAN ID can establish communications; stacks on the same CPC using the same HiperSockets CHPID that use different VLAN IDs cannot. The field value can be changed through the use of GLOBALCONFIG statements.

IP_GLOBALCONF_MLSCHKTERM

The IP_GLOBALCONF_MLSCHKTERM flag field indicates whether the stack should be terminated after writing an informational message when inconsistent configuration information is discovered in a multilevel-secure environment. The field value can be changed through the use of GLOBALCONFIG statements.

IP_GLOBALCONF_XCFGRPID

The IP_GLOBALCONF_XCFGRPID field provides a group ID value `tt` which is needed only if you want to use subplexing. If the field is not empty, *tt* is a two-digit suffix that is used in generating the XCF group name that the TCP/IP stack joins. The group name is `EZBT`*vvtt*, where the *vv* value is the VTAM XCF group ID suffix (specified with the XCFGRPID VTAM start option).

If no VTAM XCF group ID suffix was specified, the group name is `EZBTCP`*tt*.

If no VTAM XCF group ID suffix is specified and IP_GLOBALCONF_XCFGRPID is missing, the group name is `EZBTCPCS`.

These characters are also used as a suffix for the EZBDVIPA and EZBEPORT structure names, in the form `EZBDVIPA`*vvtt* and EZBEPORT*vvtt*. If no VTAM XCF group ID suffix was specified, the structure names are EZBDVIPA01*tt* and EZBEPORT01*tt*. If IP_GLOBALCONF_XCFGRPID is missing, the XCF group name is `EZBT`*vv*`CS` and the structure names are `EZBDVIPA`*vv* and `EZBEPORT`*vv*. If no VTAM XCF group ID suffix was specified, the group name is `EZBTCPCS` and the structure names are EZBDVIPA and EZBEPORT. The field value can be changed through the use of GLOBALCONFIG statements.

IP_INTERF_SOURCEVIPAINT

A Repeat group field. The IP_INTERF_SOURCEVIPAINT field has the name of the previously defined static VIPA interface which is used for SOURCEVIPA.

IP_INTERF_VMAC_ADDRESS

A Repeat group field. The IP_INTERF_VMAC_ADDRESS field contains the virtual MAC address. The OSA-Express device uses this address rather than the physical MAC address of the device for all IPv4 packets sent to and received from this TCP/IP stack. If VMAC_ADDRESS is missing, the OSA-Express device generates a virtual MAC address.

IP_INTERFACE_ASSOC_NAME

A Repeat group field. The IP_INTERFACE_ASSOC_NAME field provides the associated name for the interface, which can be the name for a Device, OSA-Express port, or TRLE definition depending on the interface type.

IP_INTERFACE_CHPID

A Repeat group field. The IP_INTERFACE_CHPID field provides the IQD Channel Path Identifier (CHPID) for the HiperSockets interface.

IP_INTERFACE_INDEX

A Repeat group field. The IP_INTERFACE_INDEX field provides the positive number assigned to the interface by the TCP/IP stack when the stack processed the configuration statement for the interface. The index value is used heavily by SNMP as the identifier of an interface for a stack because it is easier to use a number than a name.

IP_INTERFACE_INTERFACE

A Repeat group field. The IP_INTERFACE_INTERFACE field contains the name of an IPv4 or IPv6 interface.

IP_INTERFACE_INTFID

A Repeat group field. The IP_INTERFACE_INTFID field contains the configured interface ID. This ID is used to form the link-local address for the interface. The value is also appended to any manually configured prefixes for the interface to form complete IPv6 addresses on the interface.

IP_INTERFACE_IP

Repeat group field that provides the IPv4 and IPv6 addresses associated with the interface.

IP_INTERFACE_IPMASK

A Repeat group field. The IP_INTERFACE_IPMASK field provides the IPv4 subnet masks of the IPv4 addresses associated with the interface. For IPv6 addresses, the IP_INTERFACE_IPMASK field is empty, but not missing.

IP_INTERFACE_PFXLEN

Repeat group field that shows the prefix lengths for the subnet addresses of the IPv4 addresses, if any, associated with the interfaces.

IP_INTERFACE_OPTIONS

The IP_INTERFACE_OPTIONS repeat group flag field provides information about the settings for the IP stack interface configuration options. Table 486 lists the available configuration options.

Table 486. TCP/IP Interface Configuration settings

Option	Header
INTERFACE	The INTERFACE statement was employed (as opposed to DEVICE, LINK, or HOME statements).
AUTORESTART	In the event of a device failure, the TCP/IP address space attempts to reactivate the device.
NOAUTORESTART	For most device failures, the TCP/IP address space does not attempt to reactivate this device.
IPBCAST	The link both sends and receives IP broadcast packets.
MONSYSPLEX	Sysplex autonomics monitor the status of the link.
NOMONSYSPLEX	Sysplex autonomics do not monitor the status of the link.
DYNVLANREG	If a VLAN ID is configured for this link, it is dynamically registered with the physical switches on the corresponding LAN.

Table 486. TCP/IP Interface Configuration settings (continued)

Option	Header
NODYNVLANREG	If a VLAN ID is configured for this link, it must be manually registered with the physical switches on the corresponding LAN.
VMAC ROUTEALL	All IP traffic destined to the virtual MAC is forwarded by the OSA-Express device to the TCP/IP stack. If VMAC_ADDRESS is missing, the OSA-Express feature generates a virtual MAC address.
VMAC ROUTELCL	Only traffic destined to the virtual MAC and whose destination IP address is registered with the OSA-Express device by this TCP/IP stack is forwarded by the OSA-Express. If VMAC_ADDRESS is missing, the OSA-Express feature generates a virtual MAC address.
CHECKSUM	Inbound checksum calculation is performed for all packets received on this interface.
NOCHECKSUM	Inbound checksum calculation is not performed for any packets received on this interface.
ISOLATE	OSA-Express is being prevented from routing packets directly to another TCP/IP stack that share the OSA. In this mode, OSA-Express discards any packets when the next hop address was registered by another stack that share the OSA. Packets can flow between two stacks that share the OSA only by first going through a router on the LAN.
NOISOLATE	Packets are routed directly between TCP/IP stacks sharing the OSA. In this mode, if the next hop address was registered by another stack that share the OSA adapter, then OSA-Express routes the packet directly to the sharing stack without putting the packet on the external LAN.

IP_INTERFACE_SECCLASS

A Repeat group field. The IP_INTERFACE_SECCLASS field provides the security class used for IP filtering with this interface. Valid security classes are integers in the range 1 - 255. The default value is 255.

IP_INTERFACE_TYPE

A Repeat group field. The IP_INTERFACE_TYPE field identifies the Interface type. Table 487 lists the available types.

Table 487. Possible values for the Interface type

Interface type	Description
LOOPBACK6	Loop back interface. One of the IPv6 addresses associated with the interface is `::1`. Additional loopback addresses can be defined.
IPAQENET	OSA-Express QDIO Ethernet, OSA-Express2, or OSA-Express3 interface for IPv4
IPAQENET6	OSA-Express QDIO Ethernet or Fast Ethernet interface for IPv6.
IPAQIDIO6	IPv6 HiperSockets interface.
MPCPTP6	MPC Point-To-Point Data Link Control interface. The interface can be used to carry IPv6 traffic over ESCON channels, over XCF links in a sysplex, or between z/OS Communications Server images using the simulated device provided by the IUTSAMEH function in VTAM.
VIRTUAL6 S	Static virtual interface for IPv6. The interface is not associated with real hardware and is used for fault tolerance support.

Table 487. Possible values for the Interface type (continued)

Interface type	Description
IPAQIDIO	MPCIPA for HiperSockets - Another TCP/IP within the same CPC.
MPCIPA for HiperSockets	Another TCP/IP within the same CPC.
MPCPTP	MPC Point-To-Point Data Link Control interface. The interface can be used to carry IPv4 traffic over ESCON channels or between z/OS Communications Server images using the simulated device provided by the IUTSAMEH function in VTAM.
VIRTUAL	Static virtual interface for IPv4. The interface is not associated with real hardware and is used for fault tolerance support.
LOOPBACK	Loop back interface. One of the IPv4 addresses associated with the interface is 127.0.0.1. Additional loopback addresses can be defined.

IP_INTERFACE_VLAN_ID

Repeat group field that contains the Virtual LAN identifier value. Valid VLAN IDs are in the range 1 - 4094.

IP_IPA6_INTERFACE_INDEX

Repeat group field that shows the numeric index value identifying an interface. SNMP often uses such index values because the index value is easier to reference than the interface name. An index value is assigned to an interface when processing a configuration statement for the interface.

IP_IPA6_INTERFACE_NAME

Repeat group field that contains the name of an IPv6 interface.

IP_IPA6_IP

Repeat group field that provides one of the IPv6 addresses associated with an interface.

IP_IPA6_PFXLEN

Repeat group field that shows one of the prefix lengths for the subnet address of one of the IPv6 addresses associated with the interface.

IP_IPCONFIG

The IP_IPCONFIG field is a repeated flag field that provides information about IPCONFIG parameters. The field value can be changed through the use of IPCONFIG statements. The field can have the following values:

CLAWUSEDOUBLENOP

Channel programs for CLAW devices are forced to have two NOP CCWs to end the channel programs. It is required for some vendor devices, and applies to only first-level MVS systems.

DATAGRAMFWD NOFWDMULTIPATH

The transfer of data between networks is enabled. When transferring data between networks, if there are multiple equal-cost paths to a destination, TCP/IP uses the first active route found for forwarding each IP packet.

DATAGRAMFWD FWDMULTIPATH PERPACKET

The transfer of data between networks is enabled. In transferring data between networks, if there are multiple equal-cost routes to a destination network or host, TCP/IP, upon forwarding an IP packet to a given host in that destination network, selects a route on an approximate round-robin basis from a multipath routing list to that destination host. The selected route is used for routing that IP packet. Connection or connectionless

oriented IP packets using the same destination address do not always use the same route, but they do use all possible active routes to that destination host. All IP packets for a given association with a destination host are spread across the multiple equal-cost routes.

NODATAGRAMFWD
The transfer of data between networks has been stopped by disabling IP datagram routing between different network interfaces. Forwarding is disabled.

DYNAMICXCF
Dynamic XCF support is enabled.

NODYNAMICXCF XCF
Dynamic support is not enabled.

FORMAT LONG
For stacks which are not enabled for IPv6, the command output is displayed as if it could contain IPv6 addresses. If the stack is enabled for IPv6, then the presence or absence of this value does not make any difference to the command format.

FORMAT SHORT
For stacks which are not enabled for IPv6, command output is displayed as if it could contain only IPv4 addresses and not the longer IPv6 addresses. If the stack is enabled for IPv6, this value is not present. This does not make any difference to the command format.

IGNOREREDIRECT
The IGNOREREDIRECT parameter was used in an IPCONFIG statement, or you are using OMPROUTE, or you are using Intrusion Detection Services (IDS) policy to detect and discard ICMP Redirects. As a result, TCP/IP ignores ICMP Redirect packets. IPSECURITY IPv4 IP filtering and IPv4 IPSec tunnel support are activated.

IQDIOROUTING
Inbound packets that are to be forwarded by the TCP/IP stack are eligible to be routed directly between a HiperSockets device and an OSA-Express device in QDIO mode without needing to be sent to this TCP/IP stack for forwarding. This type of routing over a HiperSockets device (iQDIO) is called HiperSockets Accelerator. If specified, HiperSockets Accelerator routes are created dynamically as this TCP/IP stack learns of destination IP addresses that can be routed to or from HiperSockets links without needing to be forwarded to this TCP/IP stack.

NOIQDIOROUTING
Inbound packets that are to be forwarded by this TCP/IP stack are not routed directly between a HiperSockets device and an OSA-Express device in QDIO mode. These packets are processed and routed by this TCP/IP stack.

MULTIPATH PERCONNECTION
The multipath routing selection algorithm for outbound IP traffic is enabled. In general, multipath routing provides the routing distribution necessary to balance the network utilization of outbound packets by load splitting. Multipath routing requires multiple equal-cost routes that are either defined statically or added dynamically by routing protocols (except for RIP, which does not provide multipath routing). The MULTIPATH parameter has no effect if there are no multipath routes in the TCP/IP configuration.

MULTIPATH PERPACKET
Connection or connectionless oriented IP packets using the same source and destination address pair do not always use the same route, but do use all possible active routes to that destination host.

NOMULTIPATH
The multipath routing selection algorithm for outbound IP traffic is disabled. If there are multiple equal-cost routes to a destination, TCP/IP uses the first active route found to send each IP packet.

PATHMTUDISCOVERY
TCP/IP is to dynamically discover the PMTU, which is the smallest MTU of all the hops in the path. This is used to prevent fragmentation of datagrams.

NOPATHMTUDISCOVERY
TCP/IP is not to provide path MTU (PMTU) discovery support.

SOURCEVIPA
TCP/IP is to use the address present in the IP_TCPSTACKSOURCEVIPA field (if that field is not missing) or the corresponding virtual IP address in the HOME list as the source IP address for outbound datagrams that do not have an explicit source address. If the outgoing interface was defined with the INTERFACE statement, TCP/IP uses the VIPA specified on the SOURCEVIPAINTERFACE parameter of the INTERFACE statement instead of the HOME list.

NOSOURCEVIPA
TCP/IP is not to use the corresponding virtual IP address in the HOME list as the source IP address for outbound datagrams.

STOPONCLAWERROR
Channel programs (HALTIO and HALTSIO) are stopped when a device error is detected.

SYSPLEXROUTING
The TCP/IP host is part of an MVS sysplex domain.

NOSYSPLEXROUTING
The TCP/IP host is not part of an MVS sysplex domain.

QDIOACCELERATOR
Inbound packets that are to be forwarded by this TCP/IP stack are eligible to be routed directly between any of the following combinations of interface types:

- A HiperSockets interface and an OSA-Express QDIO interface
- Two OSA-Express QDIO interfaces
- Two HiperSockets interfaces

These packets do not need to be sent to this TCP/IP stack for forwarding. This also applies to packets that would be forwarded by the Sysplex Distributor. This type of routing is called QDIO Accelerator.

NOQDIOACCELERATOR
Inbound packets that are to be forwarded by this TCP/IP stack are not routed directly between any of the following combinations of interface types:

- A HiperSockets interface and an OSA-Express QDIO interface.
- Two OSA-Express QDIO interfaces.
- Two HiperSockets interfaces

These packets are processed and routed by this TCP/IP stack.

IP_IPCONFIG6

The IP_IPCONFIG6 repeat group flag field provides information on the current settings for IPCONFIG6 parameters. Field value for these configuration settings can be changed through the use of IPCONFIG6 statements. Information on the following configuration settings can be included in this field.

DATAGRAMFWD NOFWDMULTIPATH
The transfer of data between networks is enabled. When transferring data between networks, if there are multiple equal-cost paths to a destination, TCP/IP uses the first active route found for forwarding each IP packet.

DATAGRAMFWD FWDMULTIPATH PERPACKET
The transfer of data between networks is enabled. In transferring data between networks, if there are multiple equal-cost routes to a destination network or host, TCP/IP, upon forwarding an IP packet to a given host in that destination network, selects a route on an approximate round-robin basis from a multipath routing list to that destination host. The selected route is used for routing that IP packet. Connection or connectionless oriented IP packets using the same destination address do not always use the same route, but they do use all possible active routes to that destination host. All IP packets for a given association with a destination host are spread across the multiple equal-cost routes.

NODATAGRAMFWD
The transfer of data between networks has been stopped by disabling IP datagram routing between different network interfaces. If the TCP/IP stack is also configured to be a sysplex distributor, datagrams destined to a sysplex-distributed dynamic VIPA are forwarded to stacks, whether or not forwarding is enabled.

DYNAMICXCF
Dynamic XCF support is enabled for IPv6.

NODYNAMICXCF
Dynamic XCF support is not enabled for IPv6 on this TCP/IP.

IGNOREREDIRECT
The IGNOREREDIRECT parameter was used in an IPCONFIG6 statement, or you are using OMPROUTE. TCP/IP ignores ICMPv6 Redirect packets.

IGNOREREDIRECT
The IGNOREREDIRECT parameter was used in an IPCONFIG6 statement, or you are using OMPROUTE. TCP/IP ignores ICMPv6 Redirect packets.

IGNOREROUTERHOPLIMIT
TCP/IP will ignore any hop limit value received in a router advertisement from a router. The global hop limit value (configured by way of IPCONFIG6 HOPLIMIT) is not overridden by the router advertisement value for all routes using the interface on which the router advertisement was received.

NOIGNOREROUTERHOPLIMIT
TCP/IP will not ignore a hop limit value received in a router advertisement from a router. This results in the configured global hop limit value being overridden by the router advertisement value for all routes using the interface on which the router advertisement was received.

IPSECURITY
IPv6 IP filtering and IPv6 IPSec tunnel support are activated.

MULTIPATH PERCONNECTION
The multipath routing selection algorithm for outbound IP traffic is enabled.

In general, multipath routing provides the routing distribution necessary to balance the network utilization of outbound packets by load splitting. Multipath routing requires multiple equal-cost routes that are either defined statically or added dynamically by routing protocols (except for RIP, which does not provide multipath routing). The MULTIPATH parameter has no effect if there are no multipath routes in the TCP/IP configuration.

MULTIPATH PERPACKET
Connection or connectionless oriented IP packets using the same source and destination address pair do not always use the same route, but do use all possible active routes to that destination host. The selected route is used for routing that IP packet. Connection or connectionless oriented IP packets using the same source and destination address pair do not always use the same route, but do use all possible active routes to that destination host. All IP packets for a given association with a destination host are spread across the multiple equal-cost routes.

NOMULTIPATH
The multipath routing selection algorithm for outbound IP traffic is disabled. If there are multiple equal-cost routes to a destination, TCP/IP uses the first active route found to send each IP packet.

SOURCEVIPA
TCP/IP is to use a virtual IP address assigned to the IP_TCPSTACKSOURCEVIPA interface (if IP_TCPSTACKSOURCEVIPA is specified) or to the SOURCEVIPAINTERFACE interface as the source address for outbound datagrams that do not have an explicit source address. If multiple addresses are assigned to the IP_TCPSTACKSOURCEVIPA interface or the SOURCEVIPAINTERFACE interface, the source address is selected from among these addresses according to the default source address selection algorithm.

NOSOURCEVIPA
TCP/IP is not to use a VIPA address as the source IP address for outbound datagrams.

TEMPADDRS
TCP/IP is to generate IPv6 temporary addresses for PAQENET6 OSA-Express QDIO interfaces for which stateless address autoconfiguration is enabled.

NOTEMPADDRS
TCP/IP should not generate IPv6 temporary addresses.

IP_IPCONFIG_IPSECURITY

The IP_IPCONFIG_IPSECURITY flag field indicates whether IPv4 IP filtering and IPv4 IPSec tunnel support have been activated. The field value can be changed through the use of IPCONFIG statements.

IP_IPCONFIG6_IPSECURITY

The IP_IPCONFIG6_IPSECURITY flag field indicates whether IPv6 IP filtering and IPv6 IPSec tunnel support have been activated. The field value can be changed through the use of IPCONFIG6 statements.

IP_IPSEC_DVIPSEC

The IP_IPSEC_DVIPSEC flag field indicates whether IPsec tunnels associated with IPv4 dynamic VIPA addresses are eligible to be distributed if the dynamic VIPA address is being distributed. The IPsec tunnels are also eligible to be

moved during dynamic VIPA takeover or giveback. The field value can be changed through the use of IPSEC statements.

IP_IPSEC_LOGENABLE

The IP_IPSEC_LOGENABLE flag field indicates whether packet filter logging is enabled. If IP_IPSEC_LOGENABLE is true, then the following log messages might also be written to the syslog by the Traffic Regulation Manager Daemon (TRMD): EZD0814I, EZD0815I, EZD0821I, EZD0832I, EZD0833I, EZD0836I, and EZD0822I. The log setting on the individual default filter rules and the implicit default rules is honored. The field value can be changed through the use of IPSEC statements.

IP_IPSEC_LOGIMPLICIT

The IP_IPSEC_LOGIMPLICIT flag field indicates whether packet-filter logging is enabled for packets that are denied by the implicit default rules. IP traffic not explicitly permitted by the default IP filter rules parameters is handled by implicit default rules generated by the stack as long as the default IP filter policy is in effect. A setting of LOGIMPLICIT is honored only when filter logging is enabled on the IPSEC statement with LOGENABLE. The field value can be changed through the use of IPSEC statements.

IP_LAST_CHANGE_DATETIME

The IP_LAST_CHANGE_DATETIME field provides the date and time that the TCP/IP stack was last changed. The format of this field is DATETIME.

IP_NETACCESS_INBOUND

A repeat group field. IP_NETACCESS_INBOUND flag field indicates whether network access control checking is enabled for inbound socket commands.

IP_NETACCESS_IP

A repeat group field. IP_NETACCESS_IP field specifies an IP address or value that identifies the network or networks that require security product access control for user requests. The possible values are as follows:

IP address
Security product access control of user requests is required for the network with the specified IP address.

DEFAULT
Security product access control of user requests is required for any networks not specifically defined by other NETACCESS statement entries.

DEFAULTHOME
Security product access control of user requests is required for all IP addresses that are local to this stack and not specifically defined by other NETACCESS statement entries.

IP_NETACCESS_IPMASK

A Repeat group field. This field contains the IPv4 subnet mask. If the destination address is in IPV6 format, this field is missing.

IP_NETACCESS_OUTBOUND

A Repeat group field.This flag field indicates whether network access control checking is enabled for outbound socket commands.

IP_NETACCESS_PFXLEN

A Repeat group field. This field contains the prefix length of the Subnet address.

IP_NETACCESS_RACF_PROF

A Repeat group field. This field identifies the profile which protects the resource identified in the IP_NETACCESS_RESOURCE field. (See 1321.) The profile is simulated with the current RACF database.

IP_NETACCESS_RESNAME

A Repeat group field. This field contains the last qualifier of the resource name found in the IP_NETACCESS_RESOURCE field. (See 1321.) Effective user ids permitted to this resource are allowed to access the network.

IP_NETACCESS_RESOURCE

A Repeat group field. IP_NETACCESS_RESOURCE field identifies an SAF SERVAUTH resource. Effective user ids permitted to this resource are allowed to access the network. The resource looks like EZB.NETACCESS.sysname.tcpname.resname where

- *sysname* is the value of the MVS &SYSNAME. system symbol; it is present in the SYSNAME field.
- *tcpname* is the name of the procedure used to start the TCP/IP stack; it is present in the STACK field.
- *resname* is the 8-character value following the network specification in a NETACCESS statement. This value is present in the IP_NETACCESS_RESNAME field. (See 1321.)

IP_NETMON_PKTTRCSERVICE

The IP_NETMON_PKTTRCSERVICE flag field indicates whether the real-time TCP/IP packet trace service (SYSTCPDA) is enabled to run on the TCP/IP stack. This service enables network management applications to access trace data collected for any active packet traces or data traces. The field value can be changed through the use of NETMONITOR statements.

IP_NETMON_SMF_IPSECURITY

The IP_NETMON_SMF_IPSECURITY flag field indicates whether real-time IPSec SMF record support is enabled. The field value can be changed through the use of NETMONITOR statements.

IP_NETMON_SMF_PROFILE

The IP_NETMON_SMF_PROFILE flag field indicates whether real-time TCP/IP profile SMF event record support is enabled. The field value can be changed through the use of NETMONITOR statements.

IP_NETMON_SMFSERVICE

The IP_NETMON_SMFSERVICE flag field indicates whether the real-time SMF record information service (SYSCPSM) is enabled to run on the TCP/IP stack. The SMF record information service provides an interface for network management applications to obtain stack information in the form of SMF 119 records. Enabling or disabling this service has no effect on the SMF recording function that is available through separate configuration options on the SMFCONFIG profile statement or the FTP.DATA SMF configuration statements. The field value can be changed through the use of NETMONITOR statements.

IP_NETMON_TCPCONN_MINL

The IP_NETMON_TCPCONN_MINL field specifies the minimum connection lifetime, specified in seconds, for connections reported by the TCP connection information server. The server waits for this period before recording information about new connections; if the connection has closed in the meantime, then the

connection is not reported by the TCP connection information server. If the field contains 0, then all connections are reported. The field value can be changed through the use of NETMONITOR statements.

IP_NETMON_TCPCONNSERVICE

The IP_NETMON_TCPCONNSERVICE flag field indicates whether the real-time TCP connection information service (SYSTCPCN) is enabled to run on the TCP/IP stack. The TCP connection information service provides an interface for network management applications to obtain information about TCP connections on this stack. The field value can be changed through the use of NETMONITOR statements.

IP_PORT_BEGIN_PORT

A Repeat group field. The IP_PORT_BEGIN_PORT field contains the first port in a range of reserved ports. If missing in case UNRSV is true). The field value can change through the use of PORT and PORTRANGE statements.

IP_PORT_BIND

A Repeat group field. The IP_PORT_BIND field contains the IP address *ipaddr* which is associated with the job name present in the IP_PORT_JOBNAME field. When a job with the designated name IP_PORT_BINDs to the IPv4 INADDR_ANY address, or to the IPv6 unspecified address (`in6addr_any`), the IP_PORT_BIND is intercepted and converted to a IP_PORT_BIND to the IP address specified by *ipaddr*. Subsequent IP_PORT_BIND processing occurs as though the server instance had originally issued the IP_PORT_BIND to the IP address *ipaddr*. The field value can change through the use of PORT statements.

IP_PORT_END_PORT

A Repeat group field. The ENDPORT field contains the last port in a range of reserved ports. If the ports are not reserved (UNRSV= true), this field is missing. The field value can change through the use of PORT and PORTRANGE statements.

IP_PORT_JOBNAME

A Repeat group field. The IP_PORT_JOBNAME field specifies an MVS job name filter. If the value of the IP_PORT_PORT_USE field is *IP_PORT_JOBNAME*, then the IP_PORT_JOBNAME field indicates which job names can use the ports in the IP_PORT_BEGIN_PORT to IP_PORT_END_PORT range, or any unreserved port in case UNRSV is true. For multiple TCP reservations for the same port, or for multiple PORT UNRSV statements for the same protocol, the TCP/IP stack searches the PORT statements for the closest match (if any) to the application job name. The field value can change through the use of PORT and PORTRANGE statements.

IP_PORT_OPTIONS

The IP_PORT_OPTIONS repeat group flag field provides information about the current IP port configuration settings. Table 488 lists the settings that are reported.

Table 488. TCP/IP Configuration IP_PORT - Settings reported in IP_PORT_OPTIONS field

Option	Description
NOAUTOLOG	The TCP/IP address space is not to restart the server if it was stopped previously.

Table 488. TCP/IP Configuration IP_PORT - Settings reported in IP_PORT_OPTIONS field (continued)

Option	Description
DELAYACKS	Transmission of acknowledgments is delayed when a packet is received with the PUSH bit on in the TCP header. By default, this setting only affects connections that use a port in the specified port range. The behavior can be overridden by specifying the NODELAYACKS parameter on the TCP/IP stack TCPCONFIG profile statement, or on any of the following statements used to configure the route used by the TCP connection: • The TCP/IP stack BEGINROUTES or GATEWAY profile statements • The Policy Agent RouteTable statement • The OMPROUTE configuration statements
NODELAYACKS	An acknowledgment is returned immediately when a packet is received with the PUSH bit on in the TCP header. Only connections that use this port are affected. Specifying the NODELAYACKS parameter on the IP_PORT_PORTRANGE statement overrides the specification of the parameter on the TCP/IP stack TCPCONFIG profile statement, or on any of the following statements used to configure the route used by the TCP connection: • The TCP/IP stack BEGINROUTES or GATEWAY profile statements • The Policy Agent RouteTable statement • The OMPROUTE configuration statements
SHAREPORT	TCP/IP allows multiple listeners to listen on the same combination of port and interface. Incoming connection requests for a port are distributed among the listeners using a weighted round-robin distribution method based on the server's accept Efficiency Fraction (SEFs) of the listeners sharing the port.
SHAREPORTWLM	TCP/IP allows multiple listeners to listen on the same combination of port and interface. The listener selection is based on WLM server-specific recommendations, modified by the SEF values for each listener.
DENY	Access to unreserved ports is denied. The IP_PORT_JOBNAME is an asterisk (*) in this case.
WHENLISTEN	Port access control is targeted to TCP applications acting as servers[10] that issue an explicit IP_PORT_BIND to a user-specified unreserved port. Permission to use the unreserved port is determined when a TCP `listen` command is issued. If a `listen` command is not issued, no access control check is made.
WHENIP_PORT_BIND	Permission to use an unreserved port is determined when an explicit IP_PORT_BIND to a specific local port is issued. For the UDP protocol, it can affect UDP applications that IP_PORT_BIND to a specific local port. For the TCP protocol, it can affect TCP client applications that IP_PORT_BIND to a specific local port for outbound connections.

IP_PORT_PORT_COUNT

A Repeat group field. The IP_PORT_PORT_COUNT field contains the number of ports in a range of reserved ports. If the ports are not reserved (`UNRSV= true`), this field is missing. The field value can change through the use of PORT and PORTRANGE statements.

IP_PORT_PORTRANGE

A Repeat group field. The IP_PORT_PORTRANGE field indicates whether a PORTRANGE statement was used (as opposed to a PORT statement). The field value can change through the use of PORT and PORTRANGE statements.

IP_PORT_PORT_USE

A Repeat group field. The IP_PORT_PORT_USE field indicates how the port is used.Table 489 lists the possible use types. The field value can change through the use of PORT and IP_PORTRANGE statements.

Table 489. TCP/IP Configuration IP_PORT: Port use types

Port use type	Meaning
RESERVED	The RESERVED field specifies that the ports in the IP_PORT_BEGIN_PORT to IP_PORT_END_PORT range (or all unreserved ports in case UNRSV is true) are not available for use by any user.
AUTHPORT	The AUTHPORT field specifies that all ports in the IP_PORT_BEGIN_PORT to IP_PORT_END_PORT port range (or all unreserved ports in case UNRSV is true) are not available for use by any user except FTP, and only when FTP is configured to use PASSIVEDATAPORTS.
IP_PORT_JOBNAME	The IP_PORT_JOBNAME field contains a filter indicating which job names can use the ports in the IP_PORT_BEGIN_PORT to IP_PORT_END_PORT range (or unreserved ports in case UNRSV is true).

IP_PORT_PROTOCOL

A Repeat group field. The IP_PORT_PROTOCOL field specifies the protocol associated with a range of ports. The value can be TCP or UDP. The field value can change through the use of PORT and PORTRANGE statements.

IP_PORT_RACF_PROFILE

A Repeat group field. The IP_PORT_RACF_PROFILE field identifies the profile which protects the IP_PORT_RESOURCE resource. The profile is simulated with the current RACF database. The field value can change through the use of the PORT and PORTRANGE statements.

IP_PORT_RESNAME

A Repeat group field. The IP_PORT_RESNAME field contains the last qualifier of the `SAF SERVAUTH` resource name present in the IP_PORT_RESOURCE field. All ports in the IP_PORT_BEGIN_PORT to IP_PORT_END_PORT port range (or all unreserved ports in case UNRSV is true) are reserved for users that are permitted to this resource. The field value can change through the use of PORT and PORTRANGE statements.

IP_PORT_RESOURCE

A Repeat group field. The IP_PORT_RESOURCE field provides the name of a SAF SERVAUTH resource. All ports in the IP_PORT_BEGIN_PORT to IP_PORT_END_PORT port range (or all unreserved ports in case UNRSV is true) are reserved for users that are permitted to this resource.

The field value can change through the use of PORT and PORTRANGE statements.

The following code shows a sample resource.

```
EZB.PORTACCESS.sysname.tcpname.resname
```

where

- *sysname* is the value of the `MVS &SYSNAME.` system symbol, which is present in the SYSNAME field.
- *tcpname* is the name of the procedure used to start the TCP/IP stack; it is present in the STACK field
- *resname* is the 8-character value following the SAF keyword in a PORT or PORTRANGE statement; it is present in the IP_PORT_RESNAME field.

IP_PORT_UNRSV

A Repeat group field. The IP_PORT_UNRSV flag field indicates whether a PORT UNRSV statement was used. Such statements indicate which applications or users are permitted to access application-specified unreserved ports. The following processing rules apply to PORT UNRSV statements:

- PORT UNRSV statements control access to all unreserved ports in the range 1 - 65535 unless RESTRICTLOWPORTS is configured. However, when RESTRICTLOWPORTS is configured, PORT UNRSV statements control access to unreserved ports above port 1023 only.
- For UDP, access control is applied when an application issues a bind to a particular port number to establish a local port. For TCP, access control is applied depending on the value of the WHENBIND or WHENLISTEN parameter.
- If neither DENY nor the SAF keyword is specified, an application that matches the protocol and specified job name [the job name can be an asterisk (*)] on a PORT UNRSV statement can access unreserved ports. If DENY is specified, all applications are denied access to unreserved ports for the specified protocol.
- If the SAF keyword is specified, applications that match the PORT UNRSV statement must also have user access to the SAF SERVAUTH resource which is indicated by the SAF keyword, to be permitted to access an unreserved port. The field value can change through the use of PORT statements.

IP_ROUTE_DSTIP

A Repeat group field. The DSTIP field specifies the destination IPv4 or IPv6 address. A DEFAULT keyword in this field specifies a default IPv4 route. A DEFAULT6 keyword in this field specifies a default IPv6 route. The field value can be changed through the use of BEGINROUTES statements.

IP_ROUTE_INTERFACE, IP_ROUTE_INTERFACE_INDEX

A Repeat group field. The IP_ROUTE_INTERFACE_INDEX or IP_ROUTE_INTERFACE field is a positive number assigned to the interface by the TCP/IP stack, when the stack processed the configuration statement for the interface. This number is used often by SNMP as the interface identifier for a stack because it is easier to use a number than a name.

IP_ROUTE_IPMASK

A Repeat group field. The IP_ROUTE_IPMASK field provides a BSD style address mask of an IPv4 destination address. The field value can change through the use of BEGINROUTES statements. For IPv6 addresses, the IP_ROUTE_IPMASK field is empty, but not missing.

IP_ROUTE_NEXTHOP_IP

A Repeat group field. The IP_ROUTE_NEXTHOP_IP field specifies the host IPv4 or IPv6 address of a gateway or router that you can reach directly, and that forwards packets for the destination network or host. The field value can change through the use of BEGINROUTES statements.

IP_ROUTE_PFXLEN

A Repeat group field. The IP_ROUTE_PFXLEN field specifies the number of mask bits for an IPv4 destination address or the prefix length for an IPv6 destination address. The field value can change through the use of BEGINROUTES statements.

IP_ROUTE_REPLACEABLE

The REPLACEABLE flag field indicates that the static route can be replaced by OMPROUTE and router advertisements when a dynamic route to the same destination is discovered.

IP_ROUTE_REPLACED

The REPLACED flag field indicates that the route is a replaceable static route that has been replaced by a dynamic route. The route is not currently being used by the TCP/IP stack.

IP_RULE_CODE

The IP_RULE_CODE field specifies the Internet Control Message Protocol (ICMP) code for IP traffic. This field is only applicable when the PROTOCOL is ICMP and the IP_RULE_TYPE field has a value other than asterisk (*). For IP traffic to be permitted by this rule, the ICMP code of the traffic must match the value in the CODE field. If the value of IP_RULE_CODE is asterisk (*), any ICMP code matches. See 1328.

IP_RULE_DSTIP

The IP_RULE_DSTIP field provides the destination IP address for the outbound rule. For outbound IP traffic to be permitted by this rule, the destination IP address of the traffic must match this parameter. For inbound IP traffic to be permitted by the generated inbound rule, the source IP address of the traffic must match this parameter.

IP_RULE_DSTIPMASK

A Repeat group field. The IP_RULE_DSTIPMASK field provides the destination IPv4 subnet mask. If the destination address is IPv6, this field is missing.

IP_RULE_DSTPFXLEN

A Repeat group field. The IP_RULE_DSTPFXLEN field provides the destination subnet address prefix length.

IP_RULE_DSTPORT

A Repeat group field. For TCP or UDP traffic, the IP_RULE_DSTPORT field specifies the destination port for the outbound rule and the source port for the generated inbound rule. Outbound traffic is permitted if the *destination port* matches this field value. Inbound traffic is permitted if the *source port* matches this field value.

IP_RULE_LOG

A Repeat group field. The IP_RULE_LOG flag field indicates whether packet-filter logging is enabled for the default filter rule.

IP_RULE_PROTOCOL

A Repeat group field. The IP_RULE_PROTOCOL field indicates the type of traffic that the rule applies to. For example, rules to permit or prevent IP traffic specify the protocol TCP. The IP_RULE_PROTOCOL field can have the following values: ICMP, TCP, UDP, ICMPV6, OSPF, and `nn`. The `nn` protocol specifies traffic that has number `nn`.

IP_RULE_ROUTING

A Repeat group field. The IP_RULE_ROUTING field indicates the type of packet routing that this rule applies to. Table 490 lists the available types.

Table 490. IP_RULE ROUTING field - available values

Routing value	Meaning
LOCAL	Indicates that this rule applies to packets destined for this stack.
ROUTED	Indicates that this rule applies to packets being forwarded by this stack.
EITHER	Indicates that this rule applies to both packets that are forwarded and those that are not forwarded.

IP_RULE_SECCLASS

A Repeat group field. The IP_RULE_SECCLASS field shows the Security class. The value can be an integer in the range 0 – 255 and has a default value of 0. A value of 0 matches any security class value coded on the corresponding profile statement which defines the interface.

IP_RULE_SRCIP

A Repeat group field. The IP_RULE_SRCIP field provides the source IP address for the outbound rule. For outbound IP traffic to be permitted by this rule, the source IP address of the traffic must match this parameter. For inbound IP traffic to be permitted by the generated inbound rule, the destination IP address of the traffic must match this parameter.

IP_RULE_SRCIPMASK

A Repeat group field. The IP_RULE_SRCIPMASK field provides the destination IPv4 subnet mask. If the source address is IPv6, this field is missing.

IP_RULE_SRCPFXLEN

A Repeat group field. The SCRCPFXLEN field provides the prefix length for the source subnet address.

IP_RULE_SRCPORT

For TCP or UDP traffic, the IP_RULE_SRCPORT field specifies the source port for the outbound rule. For outbound IP traffic to be permitted by this rule, the source port of the traffic must match this parameter. For inbound IP traffic to be permitted by the generated inbound rule, the destination port of the traffic must match this parameter.

IP_SACONF_SNMP_PWDEFAULT

The IP_SACONF_SNMP_PWDEFAULT flag field indicates whether the community name (or password) used to establish contact with an SNMP agent is `public`, which is the default. For the TCP/IP SNMP subagent to communicate with the z/OS Communications Server SNMP agent, the community name must match one that is defined in the PW.SRC or SNMPD.CONF data set used by the

SNMP agent or specified on the -c parameter when the SNMP agent is started. The field value can be changed through the use of SACONFIG statements.

IP_RULE_TYPE

The TYPE field specifies a value for the Internet Control Message Protocol (ICMP) type. Valid values are an asterisk (*) or in the range 0-255, The default is asterisk (*). This value is only applicable when the PROTOCOL is ICMP. For IP traffic to be permitted by this rule, the ICMP type of the traffic must match this parameter value. If TYPE=*, any ICMP type matches. (See also, 1326.)

IP_SMF119_FTPCLIENT

The IP_SMF119_FTPCLIENT flag field whether SMF type 119 records of subtype 3 are created when a user invokes the FTP client command. The field value can be changed through the use of SMFCONFIG statements.

IP_SMF119_IFSTAT

The IP_SMF119_IFSTAT flag field indicates whether SMF type 119 records of subtype 6 containing statistics related to LINK utilization are created. The field value can be changed through the use of SMFCONFIG statements.

IP_SMF119_IPSECURITY

The IP_SMF119_IPSECURITY flag field indicates whether SMF type 119 records of subtypes 77 and 78 are created when a dynamic tunnel is added and removed. Also, SMF type 119 records of subtypes 79 and 80 are created when a manual tunnel is activated or deactivated. The field value can be changed through the use of SMFCONFIG statements.

IP_SMF119_PORTSTAT

The IP_SMF119_PORTSTAT flag field indicates whether SMF type 119 records of subtype 7 containing statistics related to reserved PORT utilization are created. The field value can be changed through the use of SMFCONFIG statements.

IP_SMF119_TCPINIT

The IP_SMF119_TCPINIT flag field indicates whether SMF type 119 records of subtype 1 are created when TCP connections are established. The field value can be changed through the use of SMFCONFIG statements.

IP_SMF119_TCPIPSTACK

The IP_SMF119_TCPIPSTACK flag field indicates whether SMF type 119 records of subtype 8 are created when a TCP/IP stack is activated and when it is terminated. The field value can be changed through the use of SMFCONFIG statements.

IP_SMF119_TCPIPSTAT

The IP_SMF119_TCPIPSTAT flag field indicates whether SMF type 119 records of subtype 5 containing TCP/IP statistics are created. The field value can be changed through the use of SMFCONFIG statements.

IP_SMF119_TCPTERM

The IP_SMF119_TCPTERM flag field indicates whether SMF type 119 records of subtype 2 are created when TCP connections are terminated. The field value can be changed through the use of SMFCONFIG statements.

IP_SMF119_TN3270CLIENT

The IP_SMF119_TN3270CLIENT flag field indicates whether SMF type 119 records of subtype 22 and 23 are created when the TSO Telnet Client code starts or ends a connection. The field value can be changed through the use of SMFCONFIG statements.

IP_SMF119_UDPTERM

The IP_SMF119_UDPTERM flag field indicates whether SMF type 119 records of subtype 10 are created when a UDP Socket is closed. The field value can be changed through the use of SMFCONFIG statements.

IP_SYSPLEX_GROUP

The SYSPLEX field provides the group name for the sysplex.

IP_TCP_RESTRICTLOWPORTS

The IP_TCP_RESTRICTLOWPORTS flag field indicates whether TCP ports 1 to 1023 are reserved for users by the PORT and PORTRANGE statements. In this case, applications that have a dependency on being able to obtain an available TCP port in the 1 - 1023 range without having that port explicitly reserved for its use should be run as APF authorized or superuser. The use of RESTRICTLOWPORTS increases system security. The field value can be changed through the use of TCPCONFIG statements

IP_TCPSTACKSOURCEVIPA

The IP_TCPSTACKSOURCEVIPA field specifies the IPv4 address used as the source IP address for outbound TCP connections. if SOURCEVIPA is one of the values of the IPCONFIG field. The address must be a static VIPA or an active dynamic VIPA (DVIPA). The field value can be changed through the use of IPCONFIG statements.

IP_TCPSTACKSOURCEVIPA6

The IP_TCPSTACKSOURCEVIPA6 field specifies the name of a static VIPA or a dynamic VIPA interface. If IP_SOURCEVIPA is one of the values of the IP_IPCONFIG6 field and if the interface has multiple IP addresses, then the *sourcevipa* address for outbound packets is selected from among these addresses according to the default source address selection algorithm. The field value can be changed through the use of IPCONFIG6 statements.

IP_UDP_RESTRICTLOWPORTS

The IP_UDP_RESTRICTLOWPORTS flag field indicates whether UDP ports 1 to 1023 are reserved for users by the PORT and PORTRANGE statements. In this case, applications that have a dependency on being able to obtain an available UDP port in the 1 - 1023 range without having that port explicitly reserved for its use should be run as APF authorized or superuser. The use of RESTRICTLOWPORTS increases system security. The field value can be changed through the use of UDPCONFIG statements.

IP_VIPA_ACTIVE

A Repeat group field. The IP_VIPA_ACTIVE field indicates whether the Dynamic Virtual IP (DVIPA) address is currently active.

IP_VIPA_INTERFACE

A Repeat group field. The IP_VIPA_INTERFACE field contains the name of the IPv6 interface.

IP_VIPA_IP

A Repeat group field. The IP_VIPA_IP field contains the Dynamic Virtual IP address (DVIPA).

IP_VIPA_IPMASK

A Repeat group field. The IP_VIPA_IPMASK field contains the IPv4 subnet mask. If the destination address is in IPV6 format, this field is missing.

IP_VIPA_PFXLEN

A Repeat group field. The IP_VIPA_PFXLEN field contains the prefix length of the Subnet address.

IP_VIPA_RACF_PROFILE

A repeat group field. This field identifies the profile that protects the resource identified in the IP_VIPA_RESOURCE field. The profile is programmatically derived using the current RACF database and RESOURCE as inputs.

IP_VIPA_RESNAME

A repeat group field. This field contains the last qualifier of the resource name found in the IP_VIPA_RESOURCE field. Effective user ids with at least READ access to this resource are allowed to:

- Create an application-specific DVIPA, specified by a specific VIPARANGE statement and by the SIOCSVIPA IOCTL call, the SIOCSVIPA6 IOCTL call, or the MODDVIPA utility.
- Delete a DVIPA that was created by using the same profile and the SIOCSVIPA IOCTL call, the SIOCSVIPA6 IOCTL call, or the MODDVIPA utility.

IP_VIPA_RESOURCE

A repeat group field. This field identifies an SAF SERVAUTH resource name. Effective user ids with at least READ access to this resource are allowed to:

- Create an application-specific DVIPA, specified by a specific VIPARANGE statement and by the SIOCSVIPA IOTCL call, the SIOCSVIPA6 IOTCL call, or the MODDVIPA utility.
- Delete a DVIPA that was created by using the same profile and the SIOCSVIPA IOTCL call, the SIOCSVIPA6 IOTCL call, or the MODDVIPA utility.

The SAF SERVAUTH resource name has the following format: `EZB.MODDVIPA.`*`sysname`*`.`*`tcpname`*`.`*`resname`*. The variable identifiers have the following meanings:

sysname is the value of the MVS `&SYSNAME.` system symbol. The value comes from the `SYSNAME` field.

tcpname is the name of the procedure used to start the TCP/IP stack. The value comes from the `STACK` field.

resname is the 8-character value following the `SAF` keyword in a `SAFNAME` statement. The value comes from the `IP_VIPA_RESNAME` field.

IP_VIPA_RANK

A Repeat group field. The IP_VIPA_RANK field specifies the intended order of the Virtual IP addresses in the VIPABACKUP statement. The VIPAs are listed in their respective backup chains, relative to other stacks in those backup chains. Larger numerical rank values move the respective stacks closer to the beginning

of the backup chain. Lower values indicate a position nearer to the end of the backup chain, while higher values indicate a position nearer to the beginning of the chain.

IP_VIPA_OPTIONS

The IP_VIPA_OPTIONS repeat group flag field provides information on the following configuration settings for the VIPA.

MOVEABLE IMMEDIATE
This value indicates whether the dynamic VIPA whose address is present in the IP field can be activated on this TCP/IP stack if the DVIPA is not already active elsewhere in the sysplex. If the DVIPA has been activated and the TCP/IP stack where the DVIPA is defined by a VIPADEFINE statement is subsequently activated, the DVIPA is activated immediately on that TCP/IP stack. The TCP connections to this TCP/IP stack are preserved. The MOVEABLE IMMEDIATE parameter is used only for activating the DVIPA when it is not already active in the sysplex. If the DVIPA is active, this parameter is ignored.

MOVEABLE NONDISRUPTIVE
Indicates an immediate, nondisruptive movement of a dynamic VIPA from one stack to another stack. A dynamic VIPA in the VIPARANGE statement can be moved to another stack when that stack requests ownership of the DVIPA as the stack creates it. This ownership request occurs under the following conditions:

- when an application binds to the DVIPA,
- when the MODDVIPA utility is used to create the DVIPA through the SIOCSVIPA or SIOCSVIPA6 ioctl
- when the application directly issues the SIOCSVIPA or SIOCSVIPA6 ioctl.

The new owning stack forwards packets for any existing connections to the original stack in order that the existing connections are not disturbed. All new connection requests are directed to the new owning stack.

CPCSCOPE
Indicates that the dynamic VIPA whose address is present in the IP field is specific to the central processor complex (CPC) on which it is defined. The VIPA is not moved to or taken over by another TCP/IP stack that is in a different CPC. A DVIPA defined with this characteristic can be used as the default route for incoming requests from Tier1 targets on this CPC. The Tier 1 target addresses must be on the same subnet as that determined by the address mask value present in the IP_VIPA_IP_VIPA_ field.

TIER1
The TIER1 field Indicates that the dynamic VIPA whose address is present in the IP field is used to distribute incoming requests to non-z/OS targets (for example, DataPower appliances or Linux hosts running on system Z).

TIER2
The TIER2 field indicates that the dynamic VIPA whose address is present in the IP field is used to distribute incoming requests from Tier1 targets to the group of server applications that is named.

SERVICEMGR
The SERVICEMGR field indicates that sysplex distributor performs Multinode Load Balancing (MNLB) by functioning as a Service Manager (in place of the Cisco LocalDirector). For these distributed dynamic VIPAs, SERVICEMGR has no effect if a VIPADISTRIBUTE DEFINE statement does not exist for the dynamic VIPA or VIPAs. SERVICEMGR is optional and can

be specified on a VIPABACKUP statement only when MOVEABLE is also specified. This parameter is used only for activating the DVIPA when it is not already active in the sysplex. If the DVIPA is active when the VIPABACKUP statement is processed, this parameter is ignored.

IP_VIPA_TYPE

A Repeat group field IP_VIPA_TYPE field identifies the Dynamic Virtual IP address (DVIPA) entry type. The following types are possible.

VIPABACKUP
This entry type designates one or more dynamic VIPAs for which this stack provides automatic backup.

VIPADEFINE
This entry type designates one or more dynamic VIPAs that this stack should initially own and support. Other stacks can provide backup for these VIPAs if this stack fails.

VIPARANGE
This entry type indicates whether a subnet for dynamic VIPA activation requests was honored through a BIND, SIOCSVIPA IOCTL, or SIOCSVIPA6 IOCT operation is to be defined or deleted. The value can be DEFINE or DELETE.

JOBCLASS

This field describes the JES job class in which the job generating the SMF record was running. It is a single character in the range A..Z, 0..9. This field is available in SMF record types 5 (Job Termination), 26 (JES Job Purge), and 30.

JOBELAPSED

Elapsed time for a job. This field is found in job termination records (SMF record type 5 and type 30, subtype 5). It indicates the time between the job start (for example, selected by an initiator) and the job end (the moment the job termination record was written). The time is indicated in minutes, rounded down; for example, SELECT JOBELAPSED<5 selects all job termination records with an elapsed time of up to 4 minutes, 59 seconds.

JOBID

This field provides the JES2 or JES3 jobid and can be found in the following record types:

- Accounting records (SMF record types 30 and 32).
- CICS monitoring records (SMF record type 110, subtype 1).
- For data set and ICF catalog activity records, it is derived using the job tag system (These records are SMF record types 14, 15, 17, 18, 60, 61, 62, 64, 65 and 66).
- CSSMTP client records (SMF record type 119) with subtypes 50 and 51 if non-blank and non-null.
- JES Job Purge records (SMF record type 26).
- RACF processing and audit records.
- Data sets and UNIX file system activity records (SMF record types 14, 15, 17, 18, 60, 61, 62, 64, 65, 66, 80, 83 and 92).
- CSSMTP mail and spool records (SMF record type 119, subtypes 50 and 51).

Depending on the record context, the value of JOBID can be in the following formats:

- Typical JES job: `J0Byyyyy`

- Started task control job: TSUyyyyy
- TSO/E user: STCyyyyy
- APPC/MVS transaction: Axxxxxxx

In these values, yyyyy and xxxxxxx are decimal numbers.

JOBNAME

Job or session name. This field is found in all job-related records.

The JOBNAME field is omitted if it is present in the record but only contains hex null characters. This most often occurs with TSO user logons (RACF processing records with EVENT=1) and with accesses during the logon process of a TSO user.

If the optional correlation header section is present in the SMF record and the field contains non-blank, non-null information, this field also available in the SMF record types: 100, 101, 102, and 110. It can also be found in CSSMTP client records (SMF record type 119) with subtypes 48, 49, 50, 51, and 52 if non-blank and non-null.SMF record types.

JOBTAG

The JOBTAG field is a compound field containing the information required to uniquely identify a job, for example, system id, jobname, reader date, and reader time. This field is found in all job-related records. It can be used for output only.

The job tag consists of 4 characters system id, 8 characters jobname, 11 characters reader date and 11 characters reader time, separated by spaces. The job tag for a job on system MLS1, with jobname SYSHSM, reader date 31 JAN 1994 and reader time 12:05:01.12 would be **'MLS1 31 JAN 1994 12:05:01.12 SYSHSM'**.

KEY_LABEL

Repeated field that contains the key labels associated with the event described by the SMF record. For record type 14, this field returns the values from the labels that identify the key for encrypting the data that was written to tape. For RACF processing records (type 80 and 83, subtype 1), this field contains the PKDS key label from relocate section 398. This field can contain up to 64 bytes of text, and is by default shown with that length.

KEY_LABEL_ENCODING

This repeated field contains the encoding for key label(s) associated with the event described by the SMF record. For record type 14, it is filled with either H or L, indicating Hash or Label encoding.

KEYRING_NAME

This field is only found in RACF processing records (SMF record type 80) and corresponds with RACF_SECTION(320). It contains the name of the keyring that is associated with this event. By default, this field is shown with a length of 64, though the contents can reach a length of 237 characters.

KERB_NAME

This field is only found in RACF processing records (SMF record type 80) and corresponds with RACF_SECTION(333). If the user that caused this record to be written has authenticated himself to the system using Kerberos, this field will contain the Kerberos principal name.

KERB_SOURCE

This field is only found in RACF processing records (SMF record type 80) and corresponds with RACF_SECTION(334). If the user that caused this record to be written has authenticated himself to the system using Kerberos, this field will contain the Kerberos login request source.

KERB_STATUS

This field is only found in RACF processing records (SMF record type 80) and corresponds with RACF_SECTION(335). If the user that caused this record to be written has authenticated himself to the system using Kerberos, this field will contain the Kerberos KDC status code.

LDAP_ENTRY_NM

This field is found only in LDAP R_auditx records (SMF record type 83 - subtype 3) and corresponds to RACF_SECTION(204). The field contains the target entry (for example, the Distinguished Name) of the operation: BIND, DELETE, ADD, and so on.

LDAP_CLIENT_SECL

This field is found only in LDAP R_auditx records (SMF record type 83 - subtype 3) and corresponds to RACF_SECTION(106). The field contains the LDAP client security label.

LDAP_CONN_ID

This field is only found in LDAP (R_auditx) records (SMF record type 83 - subtype 3) and corresponds to RACF_SECTION(103). The field contains an internal connection ID for the LDAP connection. The ID can be used to group operations performed on the same LDAP connection.

LOGSTR

SAF log string. This field is found in RACF processing and R_auditx records (SMF record type 80 and 83), ACF2 resource use, and ACF2 event records.

If you want to select records based on the contents of the log string, use the substring scan operator (`=:`) because a log string rarely contains a string at a fixed position. For example, to select all log strings with the word SDSF, use SELECT LOGSTR=:SDSF.

The default output length of LOGSTR is 64 characters; the full length might be up to 255 characters. To display the full LOGSTR in a column of limited width, use the WRAP output modifier, e.g. LOGSTR(WRAP,40). When LOGSTR reflects an executed CKGRACF command, and that command has more than 255 characters, part of the command is not present in LOGSTR. Devising a shorter REASON string will often help to limit the size of a CKGRACF command to 255 characters.

MEMBER

The `MEMBER` field returns the name of a member that has been changed. This field is supported in the following SMF record types:

- DFSMS statistics and configuration records (SMF record type 42, subtypes 21, 24, 25, and 26).
- `INPUT` or `RDBACK` Data Set Activity (SMF record type 14)
- `OUTPUT`, `UPDAT`, `INOUT`, or `OUTIN` Data Set Activity (SMF record type 15)
- TCP/IP profile event record (SMF record type 119, subtype 4)

For SMF records that are created by DFSMS Statistics and Configuration change or rename events (SMF record type 42, subtypes 14, 15, 21, 24, 25, and 26). This

field returns the name of a PDS or PDSE member that has been changed or renamed. The action that caused the change is reported in the ACTION field. (See 1276.)

For SMF type 119 subtype 4 and subtype 48 records, MEMBER is a repeated field. With each field entry is a member name which is found, between brackets, after a profile information data set name. The data set name can be found in the DATASET field. With SMF 119 subtype 4 records, thedata set followed by the member between brackets can be found in the IP_DSNMEM field. Each IP_DSNMEM entry was specified on an OBEYFILE command, or it is the default library found in the standard search sequence, or it was specified on an INCLUDE statement.

MEMBER_ALIAS

The MEMBER_ALIAS field only supported for SMF records created by DFSMS Statistics and Configuration Delete events (SMF record type 42, subtype 21). This field returns the names of aliases that were deleted when the PDSE member they were associated with (from the MEMBER field) was deleted.

MEMBER_OLDNAME

The MEMBER_OLDNAME field is only supported for SMF records created by DFSMS Statistics and Configuration Rename events (SMF record type 42 subtypes 25 and 26). The value returned is the old name of the PDSE member in the MEMBER field.

MONTH

Month the record was written. For SELECT/EXCLUDE processing, specify the first three characters of the month name (for example, JAN for January). The default output is also three characters long; specify an overriding output length of 9 characters to output the full month. This field is found in all SMF record types. For SELECT/EXCLUDE processing, a range of months separated by a colon (:) is allowed, as indicated in the following examples.

```
SELECT MONTH=JAN                        /* One month */
SELECT MONTH=(DEC, SEP)                 /* Two months */
SELECT MONTH>=MAY MONTH<=NOV            /* Month range */
SELECT MONTH=MAY:NOV                    /* Month range */
```

MONTHDAY, DAY

Day in month the record was written. This is a number in the range 1 to 31. This field is found in all SMF record types. For SELECT/EXCLUDE processing, a range of month days separated by a colon (:) is allowed, as indicated in the following examples.

```
SELECT MONTHDAY=15                      /* One day */
SELECT MONTHDAY=(15, 12)                /* Two days */
SELECT MONTHDAY>=2 MONTHDAY<=20         /* Day range */
SELECT MONTHDAY=2:20                    /* Day range */
```

MSGID

Message identifier. This field of at most 9 characters is only found in z/OS Firewall Technologies records (SMF record type 109).

NAME

Full user name or programmer name. It is found in:

- Job Initiation, Termination and Accounting records (SMF record types 5, 20, 30 and 32), where the name is taken from the job card.
- RACF processing records (SMF record types 80 and 83 subtype 1), where the name is taken from the ACEE,

OMCMD_ALLOWED

This is a flag field that indicates whether the command was suppressed by the security facility. (See 1336.

OMCMD_NAME

The OMCMD_NAME field contains the name of the Omegamon major or minor command that generated the audit record.

OMCMD_TYPE

The OMCMD_TYPE field indicates the Omegamon command type. Table 491 lists the possible types.

Table 491. Omegamon command types

Code	Description
I	Immediate
C	Major
M	Minor
G	Generalized Minor
S	Info line
P	Superceded command

For more information on the command types, see "*OMEGAMON® for MVS™ User's Guide* , SC27-2356-00 available at http://publib.boulder.ibm.com/infocenter/tivihelp/v15r1/topic/com.ibm.help.doc/welcome.htm.

OMCMD_TXT

The OMCMD_TEXT field contains the command text that was entered on the OMEGAMON II® screen. Records of minor commands also reference their associated major commands. This is the command string that caused the audit record to be generated, complete with parameters.

OWNER

RACF owner of the target profile (either a user id or a group id). This field is only found in RACF processing records (SMF record types 80 and 83 subtype 1).

To select the owner specified in a RACF command, use the RACFCMD_OWNER command field instead.

PKCS11_TOKEN

This field is found in RACF processing records (SMF record type 80) for the RACDCERT event, and corresponds with RACF_SECTION(399). It is present for the token manipulation subcommands of this event (`ADDTOKEN`, `BIND`, `DELTOKEN`, `IMPORT`, and `UNBIND`) and will contain the name of the token that was affected by the command.

PRIORITY

This field is only found in z/OS Firewall Technologies records (SMF record type 109). It indicates the priority of a record, which can range from Debug (lowest priority) to Emergency (highest priority). Its value can be Debug, Informational, Notice, Warning, Error, Critical, Alert, or Emergency.

PROCNAME

JCL procedure name. This field is only found in Accounting records (SMF record type 30).

PRODUCT

This value identifies the product from which the record was obtained. Table 492 lists the supported record types and value returned for each type.

Table 492. SMF NEWLIST PRODUCT field - possible values

Record type	Value returned
Customer Information Control System (CICS) performance monitoring records (SMF record type 110)	CICS
IBM Tivoli Key Lifecycle Manager audit records ((SMF record type 83, subtype 5)	TKLM-zOS
Websphere Application Server, version 7.0 audit records (SMF record type 83, subtype 5)	WAS-zOS

PRODUCT_FMID

This value identifies the FMID for the product that generated the SMF event record. The product name is returned in the PRODUCT field. This field is supported for the following record types:

- CICS monitoring records (SMF record type 110, subtype 1)
- Security audit event records from IBM Websphere Application Server, version 7.0 and later (SMF record type 83, subtype 5)
- Security audit event records from Tivoli Key Lifecycle Manager (SMF record 83, subtype 6)

PROFILE

RACF profile name. The type of the profile is rather dependent on the record type described. For common address space work records this field describes the userid that started the job. For data set and ICF catalog records, it will be the profile for the data set described in the record. For RACF records, it might be any type of profile. For RACF commands on a user or group, the profile describes the target user or group.

The PROFILE field is found in RACF processing and R_auditx records (SMF record types 80 and 83), and is derived for SMF record types 14, 15, 17, 18, 30, 42, 60, 62, 64, 65 and 66. To derive profile names for VSAM data set activity records (SMF record types 62 and 64), a CKFREEZE file with catalog information must be available for the system.

This is a repeated field, though most records contain only one profile.

The default output length of the PROFILE field is 44, which is sufficient for all profiles in class DATASET. General resource profiles might have a length of up to 255 characters.

Warning. Unlike the NEWLIST TYPE=RACF, using a generic value with the PROFILE field means that pattern match selection is used,
e.g. PROFILE=SYS1.** matches all profiles and resources that match the pattern SYS1.**. To select a specific generic resource, enclose the profile name in quotes, for example PROFILE='SYS1.**'.

PROGRAM

Program name. This field is only found in the following record types:

- Step Termination, Accounting
- ICF export (SMF record types 4, 30, 32, 34, and 36)
- DB2 SMF type 102 subtype/IFCid 22, 145, 177, and 183
- Security audit event records from IBM Websphere Application Server, version 7.0 and later (SMF record type 83, subtype 5) and Tivoli Key Lifecycle Manager (SMF record 83, subtype 6)

The default field length is 8, but the length can be up to 128 for DB2 SMF records. The default output format for this field shows the first 8 characters of the program name which can result in truncating file names. To include the full program name, use the following format specification in CARLa scripts: `program(0,wrap)`.

QUAL

RACF QUAL field. This field is equal to the HLQ of the data set, or the QUAL field of a naming convention table and/or exit. It defines the default owner of a data set. RACF will allow access without additional access checking.

This field is derived for RACF processing records (SMF record types 80 and 83 subtype 1), ICF catalog activity records and common address space work records (SMF record types 14, 15, 17, 18, 42, 60, 61, 62, 64, 65 and 66), and HSM function statistic records.

Note that when you have a naming convention table you must use a CKFREEZE for correct processing. When you have a naming convention exit you must run the program on the local system.

Note that RACF processing records will contain the resource names instead of the data set names when SETROPTS NOREALDSN is in effect. Consequently, it is not generally possible to deduce the correct QUAL from the record contents. In this case, the HLQ of the resource will be returned. If you have a naming convention table or exit that may change the QUAL to a value different from the HLQ of the resource name, this may occasionally be incorrect.

R_ACCESS

The `R_ACCESS` field is found in IBM Websphere Application Server, version 7.0 security audit records (SMF record type 83, subtype 5) and is set from relocate section 119 (`accPermGrant`) in the record.

R_ACTION

The `R_ACTION` field contains the action which caused the record to be created on the remote system. This field applies to IBM Tivoli Key Lifecycle Manager security audit records (SMF record type 83 subtype 6). The value is taken from the text following `action=` in relocate section 150 of the record. It also applies to security audit records from IBM Websphere Application Server, version 7.0 and later (SMF record type 83 subtype 6). In these records, the value is taken from relocate section 111 (`accAction`) of the record.

This field has a maximum length of 8.

R_EVENT

The `R_EVENT` field contains the event type that generated the log record. This field applies to audit security records associated with Tivoli Key Lifecycle Manager events (SMF record type 83, subtype 6) as indicated by the field PRODUCT. (See 1337.)

The `R_EVENT` field can also be found in the IBM Websphere Application Server, version 7.0 audit records.

Table 493 lists the event information that can be displayed.

Table 493. Event qualifier codes for SMF record types 83, subtype 6

TKLM Security Audit Event	Description	SMF Code	UNLOAD keyword <event type>
-- unknown --	Unknown events	1	*KLMUNKN
SECURITY_AUTHN	Authentication events	2	*KLMAUTN
SECURITY_AUTHN_TERMINATE	Authentication termination events	3	*KLMAUTT
SECURITY_AUTHZ	Authorization checks	4	*KLMAUTZ
SECURITY_DATA_SYNC	Data synchronization events	5	*KLMSYNC
SECURITY_MGMT_AUDIT	Management operations of the audit subsystem	6	*KLMAUDI
SECURITY_MGMT_CONFIG	Configuration operations for a security server	7	*KLMCONF
SECURITY_RUNTIME_KEY	Runtime operations for certificates/keystores	8	*KLMKEYR
SECURITY_MGMT_RESOURCE	Resource management	9	*KLMRESM
SECURITY_RUNTIME	Runtime starting and stopping of security servers.	10	*KLMRUNT

Table 494. Event qualifier codes for SMF record types 83, subtype 5

Audit Event from IBM Websphere Application Server, version 7.0 and later	SMF Event Qualifier	UNLOAD keyword <event type>
SUCCESS	0	SUCCESS
INFO	1	INFO
WARNING	2	WARNING
FAILURE	3	FAILURE
REDIRECT	4	REDIRECT
DENIED	5	DENIED
ERROR	6	ERROR

R_INTENT

The R_INTENT field specifies the type of access requested when this event record was logged. This field applies to IBM Websphere Application Server, version 7.0 security audit records (SMF record type 83 subtype 5). In these records, the value is taken from relocate section 118 (`accPermCheck`) of the record.

R_LOGDATA

This repeated field returns information about a security audit event from a zLinux system (SMF record type 83, subtype 4 event records). The information is provided in a `fieldname=value` format with a separate entry for each value returned. The values are found in the relocate 114 field of the SMF record and depend on the type of event that was logged.

SMF record type 83, subtype 4 event records are only created for zLinux systems that have been set up for remote monitoring using either the *audispd* plugin or the JZOS toolkit. For additional information about these records and setting up remote auditing, see the *Enterprise Multiplatform Auditing, IBM Redbook* available at http://www.redbooks.ibm.com/abstracts/sg247472.html.

Also see, the 1344 and 1344RACF_LINK_EVENT fields.

R_LOGRECORD

The R_LOGRECORD fields contains the native Java log record for use by IBM Tivoli Compliance Insight Manager Enabler for z/OS. This field applies to security audit records (SMF type 83 subtype 6 event records). This field has a maximum length of 1024.

R_MGMT_ATTR

The R_MGMT_ATTR provides information about one or more secondary objects involved in the operation that generated this record. This field can be found in security audit records from IBM Websphere Application Server, version 7.0 and later (SMF record type 83, subtype 5). The value is taken from relocate section 155 (mgmtAttr) of the record.

R_MGMT_CMD

The R_MGMT_CMD field identifies the application-specific command that was being performed during the event that generated this record. This field can be found in security audit event records from IBM Websphere Application Server, version 7.0 or later (SMF record type 83, subtype 5). The value is taken from relocate section 154 (mgmtCmd).

R_MGMT_TYPE

The R_MGMT_TYPE field indicates the type of management operation that was being performed during the event that generated this record. This field can be found in security audit event records from IBM Websphere Application Sever, version 7.0 or later (SMF record type 83, subtype 5). The value is taken from relocate section 153 (mgmtType) of the record.

R_RESOURCE

The R_RESOURCE field contains the name of the resource in the context of the application that generated the event record. This field applies to IBM Tivoli Key Lifecycle Manager audit records (SMF record type 83, subtype 5). The value is taken from relocate section 150 (resource=[name=) of the record.

This field can also be found in security audit event records from IBM Websphere Application Server, version 7.0 or later (SMF record 83, subtype 5). In these records, the value is taken from relocate section 114 (accApplName) of the record.

This field has a maximum length of 64. The actual length might be longer than the default length.

R_RESULT

The R_RESULT field This field is found in security audit event records from IBM Websphere Application Server, version 7.0 or later (SMF record 83, subtype 5). The value is taken from relocate section 114 (accDecision) of the record.

R_ROLECHECK

The R_ROLECHECK field indicates the roles that were checked when the event record was generated. This field is found in security audit records from IBM

Websphere Application Server, version 7.0 or later (SMF record 83, subtype 5). The value is taken from relocate section 120 (accRoleCheck) of the record.

R_ROLEGRANT

The R_ROLEGRANT field indicates the roles that were granted when the event record was generated. This field is found in security audit records from IBM Websphere Application Server, version 7.0 or later (SMF record 83, subtype 5). The value is taken from relocate section 121 (accRoleGrant)) of the record.

R_USER

The R_USER field contains the userid used by the product or component for purposes of the authentication or authorization request that generated this record. This field is found in Tivoli Key Lifecycle Manager audit records (SMF record type 83, subtype 6). The value is taken from the relocate section 150 (user=[name=) of the record.

This field also applies to security audit records from IBM Websphere Application Server, version 7.0 or later (SMF record 83, subtype 5). In these records, the value is taken from relocate section 113 (accApplUser) of the record.

RACFAUTH, AUTHORITY

RACF authority used. This field is only found RACF processing and R_auditx records (SMF record type 80 and 83). It is used to select records by the RACF authority used for executing commands or accessing resources, e.g. SPECIAL or OPERATIONS. When used for output, the default output is condensed; full output split into several lines can be requested using the EXPLODE output modifier and an overriding length of 10, for example RACFAUTH(EXPLODE,10). The table [13] Table 495 shows the RACFAUTH values and their meanings.

Table 495. SMF RACFAUTH and AUTHORITY fields - values for output processing

SELECT/EXCLUDE value	Output code	Exploded output	Meaning
AUDITOR	A	Auditor	AUDITOR attribute
BYPASS BYPASSED	B	Bypass	Bypassed-user id = *BYPASS*
EXIT	X	Exit	Installation exit processing
FAILSOFT	F	Failsoft	Failsoft processing
NORMAL	N	Normal	Normal authority check
OPERATIONS	O	Operations	OPERATIONS attribute
SPECIAL	S	Special	SPECIAL attribute
SUPER SUPERUSER	Su	Superuser	OpenEdition MVS super-user (uid 0)
SYSTEM	**Sy**	System	OpenEdition MVS system function
TRUSTED	T	Trusted	Trusted/Privileged attribute

13. Bypass appears for actions on operator consoles where no operator is logged on (and is not required to logon), and success auditing has been requested for OPERCMDS profiles.

Note: For SELECT/EXCLUDE processing, only the =, <>, and ¬= relational operators can be used.

RACFCMD

RACF logged command. This field is found in RACF processing records (SMF record types 80 and 83 subtype 1) for events dealing with RACF commands. To find all records with a RACFCMD field, select either EXISTS(RACFCMD) or EVENT=ALLCOMMAND.

To select specific RACF commands you can do a field compare on the RACFCMD field or use the EVENT field. To select the target profile (data set, general resource, user, or group), use the PROFILE field. To select the target user of a command, use the RACFCMD_USER field. To select the target group of a command, use the RACFCMD_GROUP field. To select RACF commands where specific keywords or options were used, use the RACFCMD_KEYWORDS field.

The RACFCMD field is a repeated field; the first entry prints the RACF command name; each following entry prints a logged command parameter, appended by <**Ignored**> for parameters ignored because of insufficient authority, and <**Error**> for parameters ignored because of a processing error. Passwords, which are not logged in SMF records, are indicated by the string <**Password**>.

The default output length of the RACFCMD field is 64 characters; the full length may be up to 32000 characters for SETROPTS commands. To print the command in one string, use the output modifier HORIZONTAL, e.g. RACFCMD(HORIZONTAL). To print long commands in a column, use the output modifiers HORIZONTAL and WRAP, e.g. RACFCMD(WRAP,HORIZONTAL,60).

Note: The RACFCMD field cannot be used for forward recovery (by reissuing the RACF commands), because the command result depends on the issuer, and with forwarded recovery the issuer is generally someone else. RACF does log some implied default parameters, but not all implied parameters (e.g. the current user as owner). The RACFCMD field may therefore not correspond exactly to the command typed, but it will be equivalent.

RACFCMD_AUTH

The (new) group authority specified in a RACF logged command. This field is found in RACF processing records (SMF record types 80 and 83 subtype 1) for events dealing with RACF commands.

The RACFCMD_AUTH field is defined for ADDUSER, ALTUSER, and CONNECT commands. Possible RACFCMD_AUTH values are documented in the following table (increasing sort order).

Table 496. SMF record RACFCMD_AUTH field - possible values and descriptions

RACFCMD_AUTH value
USE
CREATE
CONNECT
JOIN

RACFCMD_EFFECTIVE

RACF logged command, without ignored and erroneous keywords and values. This field is found in RACF processing records (SMF record types 80 and 83 subtype 1) for events dealing with RACF commands. It can be used for output and SELECT/EXCLUDE processing.

The RACFCMD_EFFECTIVE field is a repeated field; the first entry prints the RACF command name; each following entry prints a logged command parameter. Parameters ignored because of insufficient authority, and parameters ignored because of a processing error is not shown. Passwords, which are not logged in SMF records, are indicated by the string <Password>.

RACFCMD_GROUP

The target group of a RACF logged command. This field is found in RACF processing records (SMF record types 80 and 83 subtype 1) for the ADDUSER, ALTUSER, ADDGROUP, ALTGROUP, CONNECT, DELGROUP, REMOVE, and PERMIT commands.

For ADDGROUP, ALTGROUP and DELGROUP this field reports the group that is defined or altered; it is equal to the RESOURCE and PROFILE fields.

For ADDUSER, ALTUSER, CONNECT and REMOVE, this field reports the group that is used to define, alter or remove a connect. The value corresponds to the value of the DFLTGRP keyword for ADDUSER and the GROUP keyword for ALTUSER, CONNECT and REMOVE. (The RESOURCE and PROFILE fields describe the target user.)

For PERMIT this field reports all PERMIT ids known to be groups. Note that this requires access to a RACF database or unload, with the group present in the DB, because the SMF records contain the IDs specified on the PERMIT commands, without the indication whether they are users or groups.

RACFCMD_KEYWORDS

The repeated field contains the keywords used with a logged RACF command.

This field contains one repeat-group entry for each keyword used in a RACF command. The RACF command itself, and the *values* used with the keywords, are not included. So, for the command CONNECT XX GROUP(YY) NOSPECIAL AUTHORITY(USE), the RACFCMD field would contain the values GROUP, NOSPECIAL, and AUTHORITY.

The main use of this field is to select or exclude commands that use specific keywords that are allowed or disallowed. For instance, to select all CONNECT commands that use any parameter other than GROUP, use SELECT EVENT=CONNECT RACFCMD_KEYWORDS<>GROUP. A list of keywords, as well as substrings and generic values, may be specified as with any other character field.

RACFCMD_KEYWORDS_EFF

The repeated field contains the effective (not erroneous or ignored) keywords used with a logged RACF command. It can be used for output and SELECT/EXCLUDE processing.

This field contains one repeat-group entry for each keyword used in a RACF command. The RACF command itself, and the values used with the keywords, are not included. So, for the command CONNECT XX GROUP(YY) SPECIAL AUTHORITY(USE), the RACFCMD_KEYWORDS_EFF field would contain the values GROUP, SPECIAL, and AUTHORITY. If the issuing user did not have authority to issue the SPECIAL keyword for this connect, the field would only contain the values GROUP and AUTHORITY.

The main use of this field is to select or exclude commands that use specific keywords that are allowed or disallowed. For instance, to select all CONNECT commands that use any parameter (that actually got executed) other than GROUP, use SELECT EVENT=CONNECT RACFCMD_KEYWORDS_EFF<>GROUP. A list of keywords, as well as substrings and generic values, may be specified as with any other character field.

RACFCMD_OWNER

The (new) owner specified in a RACF logged command. This field is found in RACF processing records (SMF record types 80 and 83 subtype 1) for events dealing with RACF commands.

The RACFCMD_OWNER field is defined for ADDGROUP, ADDSD, ADDUSER, ALTDSD, ALTGROUP, ALTUSER, CONNECT, RALTER, RDEFINE, and REMOVE commands.

RACFCMD_USER

The target user of a RACF logged command. This field is found in RACF processing records (SMF record types 80 and 83 subtype 1) for events dealing with RACF commands.

The RACFCMD_USER field is defined for ADDUSER, ALTUSER, CONNECT, DELUSER, PASSWORD, REMOVE, RACDCERT, RACLINK and PERMIT commands.

For all events except PERMIT RACDCERT and RACLINK, it is equal to the RESOURCE and PROFILE fields.

For the PERMIT command, it reports all PERMIT ids known to be users. Note that this requires access to a RACF database or unload, with the user present in the DB, because the SMF records contain the IDs specified on the PERMIT commands, without the indication whether they are users or groups.

For the RACLINK commands the target user is reported.

For RACDCERT the userid associated with the certificate is reported.

RACF_LINK_AUDIT

Returns a link value for connecting security audit event records related to the same event. This value applies to RACF processing and remote audit event records (SMF record type 80 and SMF record type 83). Records that have the same value for the RACF_LINK_AUDIT and RACF_LINK_EVENT fields are connected to the same event.

See also 1344.

RACF_LINK_EVENT

Returns the event serial number for a security audit event from a zLinux system. This field applies to SMF record type 83, subtype 4 event records created through remote monitoring of a Linux system. Records with the same RACF_LINK_EVENT value are associated with the same event. Application-specific information about the security audit event is returned in the R_LOGDATA field.

You can use the RACF_LINK_EVENT value in combination with the RACF_LINK_AUDIT value for identifying the RACF command processing that caused the security audit event to be logged. Records that have the same RACF_LINK_EVENT and RACF_LINK_AUDIT values are associated with the same event.

SMF record type 83, subtype 4 event records are only created for zLinux systems that have been set up for remote monitoring using either the *audispd* plug-in or the JZOS toolkit. For additional information about these records and setting up remote auditing, see the *Enterprise Multiplatform Auditing, IBM Redbook* available at http://www.redbooks.ibm.com/abstracts/sg247472.html.

RACF_SECTION

This pseudo-field can be used to create user-defined SMF fields, to select and display values not provided for by the existing, built-in fields. It can be used for values described by a RACF relocate section within the SMF record. For a full description and examples of use, see "Defining fields in SMF records" on page 767.

REASON

RACF reason for logging. This field is only found RACF processing and R_auditx records (SMF record type 80 and 83). This field is used to select records by the RACF reason for logging, for example, SPECIAL users being audited or logging due to SETROPTS LOGOPTIONS.When used for output, the default output is condensed; full output split into several lines can be requested using the EXPLODE output modifier and an overriding length of 15, for example, REASON(EXPLODE,15).

The REASON field shows the information that RACF logged. When no REASON value has been specified by the issuer of the log record, the value is shown as blanks. You may select or exclude such records by using the value NONE. This value cannot be combined with other values in a list specification.

The following table shows the REASON values and their meanings.

Table 497. SMF record REASON field - values for output processing

SELECT/EXCLUDE	Output code	Exploded output	Meaning
ACCESS RESOURCE	Ac	Resource	Access to the resource is being audited due to the AUDIT option, a logging request from the RACHECK exit routine, or because the operator granted access during failsoft processing
APPLAUDIT	Ap	Applaudit	Entity audited due to SETROPTS APPLAUDIT
CLASS	Cl	Class	SETROPTS AUDIT(class) - Changes to this class of profile are being audited
CMDVIOL	Vi	CmdViol	Violation detected in command and CMDVIOL is in effect
COMMAND ALWAYS	Cm	Command	RVARY or SETROPTS command issued: these commands are always audited
COMPATMODE COMPAT	Co	Compatmode	Entity audited due to SETROPTS COMPATMODE
GLOBALAUDIT GLOBAL AUDITOR	G	Global audit	Access to entity being audited due to GLOBALAUDIT option
LOGOPTIONS	O	Logoptions	Class being audited due to SETROPTS LOGOPTIONS
NONE	blank	blank	No REASON value present in SMF record.
OMVS_AUTHORITY	Oa	OMVS authority	Audited because user does not have appropriate authority in OpenEdition MVS
OMVS_UNDEFINED	Ou	OMVS undefined	Audited because user not defined to OpenEdition MVS

Table 497. SMF record REASON field - values for output processing (continued)

SELECT/EXCLUDE	Output code	Exploded output	Meaning
RACINIT	R	Racinit failure	RACINIT failure
SECLABELAUDIT SECLABEL	Sl	Seclabel	Entity audited due to SETROPTS SECLABELAUDIT
SECLEVEL SECAUDIT	L	Seclevel	Entity audited due to SETROPTS SECLEVELAUDIT
SPECIAL	Sp	Special	SPECIAL or OPERATIONS users being audited (due to SETROPTS SAUDIT or SETROPTS OPERAUDIT).
USER	U	User	User being audited (due to ALTUSER UAUDIT)
VMEVENT VMAUDIT	Vm	VM event	VMEVENT auditing

Note: For SELECT/EXCLUDE processing, only the =, <>, and ¬= relational operators can be used.

RECNO

Record number of the current record within its input file (not overall). The RECNO field applies to the number of complete **logical** records within a single input file, counting the first record as 1. Found in all record types. Note: For SELECT/EXCLUDE processing, only the =, <>, and ¬= relational operators can be used.

RECORD

The RECORD field contains a single full record. It is designed to be used with a `DUMP` format, or in the DEFINE command. For information, see "DEFINE" on page 750, in combination with field-value manipulation functions in "Field value manipulation" on page 760.

Note: This field has format ASIS by default, which has been built specifically to keep trailing spaces and nulls intact. This format is also inherited by fields defined with RECORD as base. When trailing spaces should be trimmed, the overriding format CHAR can be used.

RECORDDESC

A descriptive string summarizing the record. This field is found in all predefined record types and is for output only. For most record types, a stock description is printed; for some record types, notably Accounting, Data set and Catalog activity, RACF/ACF2/TSS processing, and HSM function statistics, the description prints a string summarizing the record, often including the userid or data set name. The default length of the field is 150. The maximum length is 32760.

Notes:

1. The values printed by the RECORDDESC field are subject to change. Do not write applications that are dependent on the output of this field.
2. For path names to appear in the RECORDDESC fields of OpenMVS File System activity records (SMF record type 92) with subtypes 10 (open file) and 11 (close file), a CKFREEZE needs to be present in the input files of your setup.

RECORDLENGTH, RECORD_LENGTH

This field describes the length of the SMF record in bytes, including the SMF record header and the RDW. The given length is the one of the **logical** record. It is a decimal number of up to 32767. This field is available in all record types.

RELOCATE

This field is meant for debugging purposes. It is only found in RACF processing and R_auditx records (SMF record types 80 and 83). It can be used to select records containing specific relocate section codes; when used for output, all relocate sections contained in the record are printed. This is a repeated field, with one entry for each relocate section type found.

Older RACF relocate section codes are in the range 0 to 255; relocate section codes produced by OMVS auditing and Certificate processing are in the range 256 and upwards.

Note: For SELECT/EXCLUDE processing, only the = relational operator can be used.

RESOURCE

SAF resource name. This field is found in the following record types:

- RACF processing and R_auditx records (SMF record types 80 and 83)
- TSS processing records (SMF record type 80)

This field is derived for data set, ICF catalog activity records, and common address space work records (SMF record types 14, 15, 17, 18, 30, 42, 60, 62, 64, 65 and 66). To derive resource names for VSAM data set activity records (SMF record types 62 and 64), a `CKFREEZE` file with catalog information must be available for the system.

This is a repeated field. However, most records contain only one resource.

The default output length of the `RESOURCE` field is 44, which is sufficient for all resource names in the `DATASET` class. General resource names can have a length of up to 255 characters.

RTOKEN

An *output only* field that contains a string describing the contents of the Resource Security Token included in some RACF processing records (SMF record types 80 and 83 subtype 1) with EVENT=ACCESS. Because the `RTOKEN` value contains many fields–many that need not be set, the output has the format `field1: value1; field2: value2`.

To select all records with an `RTOKEN` field, use `SELECT RELOCATE=54`. To select on values contained in the `RTOKEN` field, use the derived field `RTOKEN_FLAGS`.

Note: The values printed by the `RTOKEN` field are subject to change. Do not write applications that are dependent on the output of this field.

RTOKEN_FLAGS

Describes the flags found in the Resource Security Token, which is included in some RACF processing records (SMF record types 80 and 83 subtype 1) with EVENT=ACCESS. It can be used for SELECT/EXCLUDE processing and for output; however, in most cases the RTOKEN field is more convenient for output. See the UTOKEN_FLAGS field for a description of the values in this field.

Note: The values printed by the RTOKEN_FLAGS field are subject to change. Do not write applications that are dependent on the output of this field.

SECLABEL

The security label for the user. This field is found in the following record types:

- RACF processing and R_auditx records (SMF record types 80 and 83) if your installation has activated the SECLABEL class through a SETROPTS CLASSACT(SECLABEL) command.
- DB2 records (SMF record type 102) with subtypes/IFCids 83, 87, 140, 142, 269, and 314 if non-blank and non-null.
- CSSMTP client records (SMF record type 119) with subtype 48 if non-blank and non-null.

SECURITY_EVENT

Identifies a high-level security event. Currently, zSecure Admin and Audit only support this field for the following record types:

- DB2 audit records (SMF record type 102) with subtype/IFCid 4, 5, 6, 7, 8, 9, 10, 22, 23, 24, 25, 33, 34, 35, 36, 37, 38, 39, 40, 41, 55, 63, 83, 87, 90, 91, 92, 97, 104, 106, 107, 114, 115, 116, 118, 119, 120, 140, 141, 142, 143, 144, 145, 169, 177, 219, 220, 258, 269, 270, 271, 314, 319, 350, 361, 362 if non-blank and non-null.
- z/OS UNIX File System Activity, security attribute audit records (SMF record type 92, subtype 15).

Note: The values printed by the SECURITY_EVENT field are subject to change. Do not write applications that are dependent on the default output of this field. You can use the overriding output format `dec` to use this field as a programming interface.

Table 498. SMF record SECURITY_EVENT field - output formats

Default output format	"dec" format	Explanation
Logon user success	1	Successful user logon
Logon user warning	2	Warning user logon
Logon user failure	3	Failed user logon
Logoff user	4	User logoff
Session start success	5	Successful batch/started task start
Session start warning	6	Warning batch/started task start
Session start failure	7	Failed batch/started task start
Session end	8	Batch/started task end
Access success	9	Successful access attempt
Access warning	10	Warning access attempt
Access failure	11	Failed access attempt

SIG_DATE

Text field that specifies the date that the module was signed.

SIG_ENTITY_DN

Text field that provides the program signer (End Entity) certificate subject's distinguished name.

SIG_EXPIRATION

Text field that specifies the date when the module certificate chain expires.

SIG_PROGRAM_LOADED

Flag field that indicates whether the Signature Verification program was loaded for this event record.

SIG_ROOT_DN

Text field contains the distinguished name for the root signing certificate subject's distinguished name.

SIG_TIME

Text field that specifies the time that the module was signed.

SMFDD

Contains the ddname of the Security zSecure SMF input file. The value can be *SMF* or in the range *SMF00-SMF99*. Supported for all SMF record types.

SMFUSERID, SMFUSER

User identification field from the SMF common exit parameter area. This field is found in most process-related record types. If your installation has an exit that writes a user ID in the common exit area, the value represents the user ID. Otherwise, the value is *0*.

SMF_FIELD

This pseudo-field can be used to create user-defined SMF fields, to select and display values not provided for by the existing, built-in fields. It can be used for values at a constant offset within the SMF record. For a full description and examples of use, see "Defining fields in SMF records" on page 767.

SMF_SECTION

This pseudo-field can be used to create user-defined SMF fields, to select and display values not provided for by the existing, built-in fields. It can be used for values described by a so-called self-defining section within the SMF record. For a full description and examples of use, see "Defining fields in SMF records" on page 767.

SPECIALTYPE

This field is an identifier for records that cannot be uniquely recognized from their numerical TYPE alone, either because the SMF record number for a specific application is not static (field values `ACF2`, `HSM0`, `HSM1`, `AIM`, `OMEG`, and `SECURPASS`) or because an application reuses a number that is officially assigned to another application (field value TSS). The SMF record numbers that correspond to each SPECIALTYPE is determined from the CKFREEZE file for a system, or from `SIMULATE SMF` commands. (See "SIMULATE" on page 911.)

SRCHOST

The `SRCHOST` field contains the port number of the remote host for this event record. This field is found in security audit records from IBM Websphere Application Server, version 7.0 or later (SMF record 83, subtype 5) and in NFS audit statistics records (SMF record type 42 subtype 26). The value is taken from relocate section 108 (`sessRemHost`) of the record.

SRCIP

Source IP address. This field is found in the following record types:

- z/OS Firewall Technologies records

- SMF record type 109, SMF record type 118 (IPv4)
- SMF record type 119 (IPv6)
- SMF record type 102 subtype/IFCid 269 and 319
- SMF record type 110 subtype 1 (CICS performance monitoring record)
- SMF record type 83 subtype 5 (audit records from IBM Websphere Application Server, version 7.0 or later)
- SMF record type 42 subtype 26 (NFS audit statistics)

For Websphere Application Server audit records, the value is taken from relocate section 106 (`sessRemAddr`) of the record.

SRCPORT

Source port number. This field is found in the following record types:

- z/OS Firewall Technologies records
- SMF record type 109
- SMF record type 118 (IPv4)
- SMF record type 119 (IPv6)
- SMF record type 83 subtype 5 (audit records from IBM Websphere Application Server, version 7.0 or later)

For Websphere Application Server audit records, the value is taken from relocate section 107 (`sessRemPort`) of the record.

STEPNAME

Step name. This field is found in the following record types:

- Step Termination and Accounting records (SMF record types 4, 30, 32, 33, and 34).
- z/OS UNIX File System Activity, security attribute audit records (SMF record type 92, subtype 15).
- ACF2 data set use records.

SUBSYS

This field contains the 4 character subsystem name. The SMF standard header has an architected place for a subsystem name under the control of a bit in the SMF header. If one is present, it is returned, unless it is always empty (type 41) or the flag is on by accident (type 118). In addition, some record types report a subsystem name even though the header flag says not. This applies to type 59, 99, 100, 101, and 102.

SUBSYS_TYPE

This field describes the subsystem type that generated the SMF record. It is only filled in if a CKFREEZE file is used. Currently this field only recognizes JES2 and JES3 subsystems. For other subsystems, or SMF records not created by a subsystem, it is missing. You can select on this field by using its byte-value. Table 499 shows the possible values:

Table 499. SMF record SUBSYS_TYPE field values

Subsys value	Description
X'02'	JES2
X'03'	JES3

SUBRECORD

CICS SMF 110 Monitoring performance records contain many Performance Data sections, relating to separate CICS events. These repeated sections are processed as if they are single ordinary SMF records. This field contains the full Performance subrecord. The complete SMF record can be found in the RECORD field.

SUBRECORDNO

This field returns the value of the current subrecord number within the full SMF record. This field is only supported in CICS monitoring performance records (`CICS_MONITOR_CLASS = 3`). See 1350.

SUBTYPE

This field contains the SMF record subtype and can only be used for output; for SELECT/EXCLUDE processing, it is selected implicitly with the TYPE field, see Table 500 on page 1352. This field is found in all records that have subtypes, for example SMF record types 24, 30, 32, 33, 41, 42, 83 and 110. The SMF record header is examined to determine whether subtypes are present; as a result, subtypes are also found in record types for which only basic support is available.

The following tables show supported subtype values and their meaning:

- Table 500 on page 1352 *SMF record type 24: JES2 Spool Offload SUBTYPEs*
- Table 501 on page 1352 *SMF record type 30: Common Address Space Work SUBTYPEs*
- Table 502 on page 1352 *SMF record type 32: TSO/E User Work Accounting SUBTYPEs*
- Table 503 on page 1352 *SMF record type 33: APPC/MVS TP Accounting SUBTYPEs*
- Table 504 on page 1353 *SMF record type 41: DIV ACCESS/UNACCESS SUBTYPEs*
- Table 505 on page 1353 *SMF record type 42: DFSMS Statistics and Configuration*
- Table 506 on page 1353 *SMF record type 70: RMF CPU Activity SUBTYPEs*
- Table 507 on page 1353 *SMF record type 72: RMF Workload Activity and Storage Data SUBTYPEs*
- Table 508 on page 1353 *SMF record type 74: RMF Device and XCF Activity SUBTYPEs*
- Table 509 on page 1353 *SMF record type 78: RMF Monitor I Activity SUBTYPEs*
- Table 510 on page 1354 *SMF record type 79: RMF Monitor II Activity*
- Table 511 on page 1354 *SMF record type 82: ICSF Integrated Cryptographic Facility SUBTYPEs*
- Table 512 on page 1355 *SMF record type 83: Security events SUBTYPEs*
- Table 513 on page 1355 *SMF record type 85: OAM Object Access Method SUBTYPEs*
- Table 514 on page 1356 *SMF record type 88: System Logger Data SUBTYPEs*
- Table 515 on page 1356 *SMF record type 89: Product Usage Data SUBTYPEs*
- Table 516 on page 1356 *SMF record type 90: System Status SUBTYPEs*

Subtype	Meaning
1	Job Transmitted
2	Job Received
3	SYSOUT Transmitted
4	SYSOUT Received

Table 501. SMF record type 30: Common Address Space Work SUBTYPEs

Subtype	Meaning
1	Job start
2	Interval
3	Step termination
4	Step total
5	Job termination
6	System address space

Table 502. SMF record type 32: TSO/E User Work Accounting SUBTYPEs

Subtype	Meaning
1	TSO/E User Interval
2	TSO/E User Session End
3	TSO/E User Detail Interval Record
4	TSO/E User Detail Session End

Table 503. SMF record type 33: APPC/MVS TP Accounting SUBTYPEs

Subtype	Meaning
1	APPC/MVS Transaction
2	APPC/MVS Conversation

Table 504. SMF record type 41: DIV ACCESS/UNACCESS SUBTYPEs

Subtype	Meaning
1	DIV ACCESS
2	DIV UNACCESS
3	VLF Statistics

Table 505. SMF record type 42: DFSMS Statistics and Configuration SUBTYPEs

Subtype	Meaning
20	STOW Initialize
21	Member Delete
22	DFSMSrmm Audit Records Section
23	DFSMSrmm Security Section
24	Member Add/Replace
25	Member Rename
26	NFS Create/Delete/Rename statistics

Table 506. SMF record type 70: RMF CPU Activity SUBTYPEs

Subtype	Meaning
1	RMF CPU, PR/SM™, and ICF Activity
2	RMF Cryptographic Hardware Activity

Table 507. SMF record type 72: RMF Workload Activity and Storage Data SUBTYPEs

Subtype	Meaning
1	RMF Workload Activity (compatibility mode)
2	RMF Storage data (compatibility mode)
3	RMF Workload Activity (goal mode)
4	RMF Storage data (goal mode)
5	RMF System suspend lock and GRS data

Table 508. SMF record type 74: RMF Device and XCF Activity SUBTYPEs

Subtype	Meaning
1	RMF Device Activity
2	RMF XCF Activity
3	RMF OMVS Facility Activity
4	RMF Coupling Facility Activity
5	RMF Cache Subsystem Activity
6	RMF HFS Statistics
7	RMF FICON® Director Statistics

Table 509. SMF record type 78: RMF Monitor I Activity SUBTYPEs

Subtype	Meaning
1	RMF I/O Queuing Activity (4381)
2	RMF Virtual Storage Activity

Table 509. SMF record type 78: RMF Monitor I Activity SUBTYPEs (continued)

Subtype	Meaning
3	RMF I/O Queuing Activity

Table 510. SMF record type 79: RMF Monitor II Activity

Subtype	Meaning
1	RMF Address Space State Data
2	RMF Address Space Resource Data
3	RMF Storage/Processor Data
4	RMF Paging Activity
5	RMF Address Space SRM Data
6	RMF Reserve Data
7	RMF Enqueue Contention Data
8	RMF Transaction Activity
9	RMF Device Activity
10	RMF Domain Activity
11	RMF Page Data Set Activity
12	RMF Channel Path Activity
13	RMF I/O Queuing Activity (4381)
14	RMF I/O Queuing Activity
15	RMF IRLM Long Lock Detection

Table 511. SMF record type 82: ICSF Integrated Cryptographic Facility SUBTYPEs

Subtype	Meaning
1	ICSF start
3	ICSF crypto processor added/removed
4	ICSF crypto failure or tampering
5	ICSF change to special security mode
6	ICSF key part entered through KEU
7	ICSF key part entered through KEU
8	ICSF in-storage CKDS copy refreshed
9	ICSF CKDS dynamically updated
10	ICSF PKA master key part entered
11	ICSF clear master key part entered
12	ICSF key loaded from TKE workstation
13	ICSF CKDS dynamically updated
14	ICSF PCI Cryptographic Coprocessor clear master key entry
15	ICSF PCI Cryptographic Coprocessor retained key create/delete
16	ICSF PCI Cryptographic Coprocessor TKE
17	ICSF PCI Cryptographic Coprocessor timing
18	ICSF PCI Cryptographic Coprocessor configuration
19	ICSF PCI X Cryptographic Coprocessor timing

Table 512. SMF record type 83: Security events SUBTYPEs

Subtype	Meaning
1	RACF Processing Record for Auditing Data Sets: Security Label Change
2	EIM Processing
3	LDAP audit data
4	R_auditx remote auditing service
5	IBM Websphere Application Server audit data
6	Tivoli Key Lifecycle Manager audit data

Table 513. SMF record type 85: OAM Object Access Method SUBTYPEs

Subtype	Meaning
1	OAM OSREQ Access
2	OAM OSREQ Store
3	OAM OSREQ Retrieve
4	OAM OSREQ Query
5	OAM OSREQ Change
6	OAM OSREQ Delete
7	OAM OSREQ Unaccess
32	OAM Storage Group Processing
33	OAM DASD space management
34	OAM Optical Disk Recovery Utility
35	OAM MOVEVOL Utility
36	OAM Single Object Recovery Utility
37	OAM OSMC Space Management
64	OAM LCS Optical Drive Vary Online
65	OAM LCS Optical Drive Vary Offline
66	OAM LCS Optical Library Vary Online
67	OAM LCS Optical Library Vary Offline
68	OAM LCS Optical Cartridge Eject
69	OAM LCS Optical Cartridge Entry
70	OAM LCS Optical Cartridge Label
71	OAM LCS Optical Volume Audit
72	OAM LCS Optical Volume Mount
73	OAM LCS Optical Volume Demount
74	OAM LCS Optical Write request
75	OAM LCS Optical Read request
76	OAM LCS Optical Logical Delete Request
77	OAM LCS Optical Physical Delete Request
78	OAM LCS Object Tape Write Request
79	OAM LCS Object Tape Read Request
87	OAM LCS Object Tape Volume Demount
88	OAM LCS Object Tape Logical Delete

Table 513. SMF record type 85: OAM Object Access Method SUBTYPEs (continued)

Subtype	Meaning
90	OAM LCS File System Write Request
91	OAM LCS File System Read Request
92	OAM LCS File System Physical Delete
93	OAM LCS File System Delete-Store Cleanup

Table 514. SMF record type 88: System Logger Data SUBTYPEs

Subtype	Meaning
1	System log: Stream Activity
11	System log: CF Alter Activity

Table 515. SMF record type 89: Product Usage Data SUBTYPEs

Subtype	Meaning
1	Product Usage Data
2	Product State Data

Table 516. SMF record type 90: System Status SUBTYPEs

Subtype	Meaning
1	SET TIME
2	SET DATE
3	SET DMN
4	SET IPS
5	SET SMF
6	SWITCH SMF
7	HALT EOD
8	IPL PROMPT
9	IPL SMF
10	IPL SRM
11	SET OPT
12	SET ICS
13	SET SMF
14	SET MPF
15	RESTART SMF
16	SET DAE
17	SET PFK

19	SET APPC
20	SET SCHPRM
21	SET SCH
22	SET CNGRP
23	WLM Service Definition Install

Table 516. SMF record type 90: System Status SUBTYPEs (continued)

Subtype	Meaning
24	WLM Service Policy Activation
25	Workload Management Mode Change
26	IPL LOGREC
27	ARM restarts enabled
28	ARM restarts disabled
29	SET PROG (LNKLST set activation)
30	RESET command completed
31	SET PROG (LPA Set Activation)
32	Scheduling Environment Information

Table 517. SMF record type 91: Batch Pipes/MVS Statistics

Subtype	Meaning
1	Batch pipe Subsystem Start
2	Batch pipe Subsystem Interval Expiration
3	Batch pipe Subsystem Stop
11	Batch pipe Open-Connection
12	Batch pipe Interval Expiration
13	Batch pipe Close-Connection
14	Batch pipe Creation
15	Batch pipe Deletion

Table 518. SMF record type 92: OpenMVS File System Activity SUBTYPEs

Subtype	Meaning
1	UNIX File System mounted
2	UNIX File System suspended
4	UNIX File System resumed
5	UNIX File System unmounted
6	UNIX File System remounted
7	UNIX File System moved
10	UNIX file opened
11	UNIX file closed
12	UNIX mmap service
13	UNIX munmap service
15	UNIX security attributes (APF authorization, program control, or shared library) changed.

Table 519. SMF record type 94: IBM Tape Library Dataserver Statistics SUBTYPEs

Subtype	Meaning
1	34xx Library Statistics

Table 520. SMF record type 96: The Integrated Reasoning System TIRS statistics SUBTYPEs

Subtype	Meaning
1	The Integrated Reasoning System detail statistics
2	The Integrated Reasoning System summary statistics

Table 521. SMF record type 99: System Resource Manager decision SUBTYPEs

Subtype	Meaning
1	SRM system level data
2	SRM service class data
3	SRM service class period plot data
4	SRM device cluster data
5	SRM monitored address space data
6	SRM next interval resource settings
7	SRM PAV device data
8	SRM WLM LPAR partition data
9	SRM IOS subsystem data

The subtypes for SMF record types 100, 101, and 102: DB2 Performance and Audit represent the IFCid. Its meaning can be printed with format `DB2_IFCid`. Table 522 shows the subtypes, whether they use or define numeric Data Base Ids, Object Ids, or Data Set Ids (`DBIDs`, `OBIDs`, and `DSIDs`), and what fields are filled in with detailed information from the subtype relocate sections.

Table 522. SMF record type 100, 101, and 102: DB2 Performance and Audit SUBTYPEs

Subtype	Meaning	Specific field support	Trace class or IFCID
0	Normal trace record		GLOB(3)
1	System statistics		STAT(1), MON(1), PERF(1)
2	Database statistics		STAT(1), MON(1), PERF(1)
3	Accounting		ACCT(1), PERF(2)
4	Start/modify trace	DB2_COMMAND, RECORDDESC	All
5	Stop trace	DB2_COMMAND, RECORDDESC	All
6	Read I/O start	DB2_OBJECT*, INTENT, RECORDDESC, SECURITY_EVENT	ACCT(3,8), MON(3,8), PERF(4)
7	Read I/O completion	DB2_OBJECT*, INTENT, RECORDDESC, SECURITY_EVENT	ACCT(3,8), MON(3,8), PERF(4)
8	Write I/O start	DB2_OBJECT*, INTENT, RECORDDESC, SECURITY_EVENT	ACCT(3,8), MON(3,8), PERF(4)
9	Write I/O completion	INTENT, RECORDDESC, SECURITY_EVENT	ACCT(3,8), MON(3,8), PERF(4)
10	Synchronous write I/O start	DB2_OBJECT*, INTENT, RECORDDESC, SECURITY_EVENT	PERF(4)
11	Validation exit call results		PERF(13)
12	Encode exit call results		PERF(13)
13	Hash scan input		PERF(8)

Table 522. SMF record type 100, 101, and 102: DB2 Performance and Audit SUBTYPEs (continued)

Subtype	Meaning	Specific field support	Trace class or IFCID
14	End of hash scan		PERF(8)
15	Index scan input		PERF(8)
16	Insert input		PERF(8)
17	Sequential scan input		PERF(8)
18	Exit from index scan, sequential scan, or insert		PERF(8) and IFCID(15) or IFCID(16) or IFCID(17)
19	Decode exit call results		PERF(13)
20	Lock summary		PERF(6)
21	Lock detail		PERF(7)
22	Optimizer mini-plan generation	DB2_OBJECT*, PROGRAM, RECORDDESC, SECURITY_EVENT	PERF(3)
23	Start utility	DB2_OBJECT*, RECORDDESC, SECURITY_EVENT	AUDIT(8), PERF(10)
24	Change utility	DB2_OBJECT*, RECORDDESC, SECURITY_EVENT	AUDIT(8), PERF(10)
25	End utility	DB2_OBJECT*, RECORDDESC, SECURITY_EVENT	AUDIT(8), PERF(10)
26	Sort work file obtained		PERF(3,9)
27	Sort new run		PERF(3,9)
28	Sort runs created		PERF(3,9)
29	EDM I/O start	SECURITY_EVENT	PERF(4)
30	EDM I/O end	SECURITY_EVENT	PERF(4)
31	EDM pool not large enough		PERF(1)
32	Start wait for log manager	INTENT	ACCT(3,8), MON(3,8), PERF(5)
33	End wait for log manager	RECORDDESC	ACCT(3,8), MON(3,8), PERF(5)
34	Log manager read I/O start	DSN, INTENT, RECORDDESC, SECURITY_EVENT	PERF(5)
35	Log manager read I/O completion	INTENT, RECORDDESC, SECURITY_EVENT	PERF(5)
36	Start wait for log manager non-I/O	RECORDDESC	PERF(5)
37	End wait for log manager non-I/O	RECORDDESC	PERF(5)
38	Log manager write active log I/O start	DSN, INTENT, RECORDDESC, SECURITY_EVENT	PERF(5), GLOB(3)

Subtype	Meaning
1	Websphere AS Server Activity
2	Websphere AS Container Activity
3	Websphere AS Server Interval
4	Websphere AS Container Interval

SYSNAME

The SYSNAME field specifies the name of the system. This value is used as part of the SAF resource name in the IP_PORT_RESOURCE and IP_NETACCESS_RESOURCE fields for SMF records of type 119

SYSPLEX

The name of the sysplex the SYSTEM is a part of (if applicable).

SYSTEM

The name of the system (the SMF system id, which is four characters long). Found in all record types.

SYSTYPE

Operating system type. This field is found in all record types.

Note: The output values for this field are not identical to the SELECT/EXCLUDE values; also, the default output size of this field is three characters; use an overriding length of nine to get the full output.

Table 528 lists the possible SYSTYPE values (in increasing sort order).

Table 528. SMF record SYSTYPE field - SELECT/EXCLUDE and Output values

SELECT/EXCLUDE value	Output value	Meaning
VM	VM	VM
VS2	VS2	OS/VS2
SP2 XA	SP2 (XA)	MVS/XA
SP3 ESA	SP3 (ESA)	MVS/ESA SP3
SP4 SP5	SP4 (ESA)	MVS/ESA SP4 or SP5

TERMINAL

Terminal id. This field is found in the following record types:

- Job Initiation and Accounting records (SMF record types 20, 30 and 32)
- RACF processing and R_auditx records (SMF record types 80 and 83
- HSM function statistics records
- Telnet server TCP/IP records (SMF record types 118 and 119)
- CICS subrecords (SMF record type 110, subtype 1, class 3)

The value of TERMINAL is derived using the job tag system for data set, ICF catalog activity records, RACF processing, and audit records for data sets and UNIX file system activity records (SMF record types 14, 15, 17, 18, 60, 61, 62, 64, 65 and, 66, 80, 83 and 92).

TIME

Time of day the record was written. For detailed instructions on how to use this field in SELECT/EXCLUDE specifications, see "Time fields" on page 904.

TRANSACTION

For CICS monitoring performance subrecords (SMF 110, subtype 1, subclass 3), this field returns the name of the transaction that was run. If this information is not available, this field is not reported.

TSOCMD

A string containing a TSO command name. This repeated field is only found in SMF record type 32 (TSO/E User Work Accounting), and only contains those TSO commands accounted by the installation; all other commands are collected as ***OTHER. This field can be combined with the TSOCMDCNT field.

TSOCMDCNT

A repeated field containing the number of times a given TSO command was executed. This field can only be used for output and should be combined with the TSOCMD field.

TYPE

SMF numerical record type. This field is found in all record types. When used in SELECT/EXCLUDE processing, this field is used to select types and subtypes; for output, these fields are separated in TYPE and SUBTYPE.

For SELECT/EXCLUDE processing, each record type can be further specified by a list of *subtypes*, as shown in the following examples:

```
SELECT TYPE=(20, 30, 32, 80, 83)
SELECT TYPE=(20, 30(1, 3, 4, 6), 80, 83(1))
SELECT TYPE<>(20 30(5) 80)
```

For SELECT/EXCLUDE processing, only the =, <>, and ¬= relational operators can be used.

UNITTYPE

This field can be used to select or output the device type used. It is found in data set activity records (SMF record types 14, 15, 62 and 64), ICF Catalog Activity records (SMF record type 61, 65, and 66), and Accounting records (SMF record type 30). In SMF record type 30, the unit type is not available in all subtypes, and is only available for started tasks if detail recording is on. This value can be verified using the DETAIL field of NEWLIST TYPE=SMFOPT.

Table 529 lists the possible UNITTYPE values.

Table 529. SMF record UNITTYPE field - possible values

UNITTYPE value	Meaning
3350	3350 DASD Unit
3380	3380 DASD Unit
3390	3390 DASD Unit
3400	3400 Tape Unit

Table 529. SMF record UNITTYPE field - possible values (continued)

UNITTYPE value	Meaning
3480	3480 Tape Unit
3490	3490 Tape Unit
9345	9345 DASD Unit
DASD	Unknown (output) or any (SELECT) type of DASD Unit
TAPE	Unknown (output) or any (SELECT) type of Tape Unit
????	Unknown unit type (not tape or DASD) (output-only)

Note: There is a slight difference between SELECT/EXCLUDE processing and output values: TAPE and DASD match any tape or DASD unit in SELECT/EXCLUDE processing, but is only output for an unknown type of tape or DASD unit; the value '**????**' cannot be used for SELECT/EXCLUDE processing, but is output-only. For SELECT/EXCLUDE processing, only the =, <>, and ¬= relational operators can be used.

Note: UNITTYPE is a repeated field. In the current version of Security zSecure, this repeated field can contain duplicate unit types for some record types.

UNIX_ACCESS_ALLOWED

This field of length 3 is only found in RACF processing records (SMF record type 80). It corresponds with RACF_SECTION(269), *Access allowed*. The three characters might be "-" (access not allowed); the first character can alternatively be "r" for "Access read allowed", the second "w" for "Access write allowed", and the third "x" for "Access execute allowed". See also UNIX_ACCESS_USED.

The SELECT/EXCLUDE syntax for this field is the same as for the NEWLIST TYPE=UNIX field ATTR (see "Formatting UNIX file type, attribute, and audit flag fields" on page 823). For example, you can select on "execute allowed" with UNIX_ACCESS_ALLOWED='+x'M. If access for "u" specifically is asked, an extra check is done if the corresponding UNIX_ACCESS_ORIGIN value is "user"; and likewise "g" matches only if that field is "group" and "o" when it is "other". For example, you can select on "write access allowed via the other bits" with UNIX_ACCESS_ALLOWED='o+w'M.

UNIX_ACCESS_FILENAME

UNIX_ACCESS_FILENAME shows the name of the file or directory to which access was attempted. It was verified whether the access was allowed.

This field is found in the following record types:

- RACF processing records (SMF record type 80)
- Security audit event records (SMF record type 83, subtype 5 and 6)

The `UNIX_ACCESS_FILENAME` combines information from extended-length relocate sections 263, 264, and 298. If a CKFREEZE file is present, the information in it is consulted for translating file identifiers into full path names and the like.

A CKFREEZE file contains data from a particular point in time. For example, if a `RENAMEF` event is enriched based on a CKFREEZE system snapshot from slightly before the event, the record results probably yield the *old* file name.

For some events, `UNIX_ACCESS_FILENAME` is identical to `UNIX_FILENAME`. For other events, `UNIX_ACCESS_FILENAME` is the name of the directory to which access was

attempted as a result of requesting access to UNIX_ACCESS_FILENAME. UNIX_ACCESS_FILENAME is the last qualifier of UNIX_ACCESS_PATHNAME.

The default output format for this field shows the first 256 characters of the file name are shown in the output which can exceed available space on the output line. To include the full file name, use the following format specification in CARLa scripts: `unix_access_filename(0,wrap)`

UNIX_ACCESS_INTENT

This field of length 4 is found only in RACF processing records (SMF record type 80) , NFS audit statistics records (SMF record type 42 subtype 26), and ACF2 OMVS CHECK_ACCESS records. For RACF, it corresponds with the bits in RACF_SECTION(267), "Requested access". For ACF2, it corresponds with the bits in SMFRQACC. The first character of the field can be "d" (directory search access intended) or "-" (no directory search access intended), although for DIRSRCH events, the character usually reads "-". The second character can be "r" (read access intended) or "-" (no read access intended). The third character can be "w" (write access intended) or "-" (no write access intended). The fourth character can be "x" (execute access intended) or "-" (no execute access intended).

Select/Exclude syntax for the UNIX_ACCESS_INTENT field is like the NEWLIST TYPE=UNIX field EXTATTR syntax, with characters "drwx" replacing "apsl". For example, you can select on the presence of the "r" and "w" bits with UNIX_ACCESS_INTENT='+rw'M. See “Formatting UNIX file type, attribute, and audit flag fields” on page 823 for the (extended) EXTATTR syntax supported for SELECT/EXCLUDE processing.

UNIX_ACCESS_ORIGIN

This character field of length 10 is found only in RACF processing records (SMF record type 80). It corresponds with the value of RACF_SECTION(268), "Access type (bits used to make access check)". The recognized values for this field are "user" (user bits used), "group" (group bits used), "other" (other bits used), "no" (no bits present), "user ACL" (user ACL entry used), "group ACL" (group ACL entry used), "no ACL" (an ACL entry exists but it could not be retrieved), "restricted" (other bits not used because of the RACF user's RESTRICTED attribute), and "n/a" (the security label of the user is insufficient for access). Unrecognized values are printed in decimal.

The SELECT/EXCLUDE syntax for this field allows a list of values, e.g., UNIX_ACCESS_ORIGIN=('user'c,'group'c,'other'c). Note that you must specify that case is to be kept. Note that values of "user", "group" and "other" can also be selected on in combination with UNIX_ACCESS_ALLOWED and UNIX_ACCESS_USED--see there. For backwards compatibility, the one-character selection codes 'u'c, 'g'c, 'o'c, and - are still supported for now, too; these are interpreted as 'user', 'group', 'other' and 'no', respectively.

UNIX_ACCESS_PATHNAME

UNIX_ACCESS_PATHNAME shows the path name of the file or directory to which access was attempted. It was verified whether the access was allowed. The field is found in the following record types.

- RACF processing records (SMF record type 80)
- Security audit event records (SMF record type 83, subtype 5 and 6)

For RACF, UNIX_ACCESS_PATHNAME combines information from extended-length relocate sections 263, 264, and 298. If a CKFREEZE is present, the information in it is consulted for translating file identifiers into full path names and the like.

A CKFREEZE file denotes a particular point in time. For example, if a RENAMEF event is enriched based on a CKFREEZE system snapshot from slightly before the event, this field value will probably yield the full *old* path name.

For some events, UNIX_ACCESS_PATHNAME is identical to UNIX_PATHNAME. For other events, UNIX_ACCESS_PATHNAME reflects the directory to which access was attempted as a result of requesting access to UNIX_PATHNAME. In the latter case, UNIX_PATHNAME is the concatenation of UNIX_ACCESS_PATHNAME and UNIX_FILENAME.

The default output format for this field shows the first 256 characters of the file name are shown in the output which can exceed available space on the output line. To include the full path name, use the following format specification in CARLa scripts: `unix_access_pathname(0,wrap)`

UNIX_ACCESS_USED

This field of length 3 is only found in RACF processing records (SMF record type 80). It combines information from RACF_SECTION(267), "Requested access" and RACF_SECTION(269), "Access allowed". It indicates which kinds of access were both intended and allowed. Its contents are similar to those of the UNIX_ACCESS_ALLOWED field, but the corresponding character for each type of access is set to "-" if the access was not requested.

The SELECT/EXCLUDE syntax for this field is the same as for the NEWLIST TYPE=UNIX field ATTR (see “Formatting UNIX file type, attribute, and audit flag fields” on page 823). You can select on "write access" with UNIX_ACCESS_USED='+w'M. If access for "u" specifically is asked, a check is done if the corresponding UNIX_ACCESS_ORIGIN value is "user"; and likewise "g" matches only if that field is "group" and "o" when it is "other". For example you can select on "successfully reading your own file" with UNIX_ACCESS_USED='u+r'M.

If UNIX_ACCESS_USED is "---" a violation has occurred, unless UNIX_ACCESS_ORIGIN indicates that the access check could not be performed ("no ACL") or does not apply ("no").

UNIX_FILENAME

`UNIX_FILENAME` shows the name of the file or directory to which access was requested. This field is found in the following record types:

- RACF processing records (SMF record type 80)
- OpenMVS File System activity records (SMF records type 92)
- TCP/IP statistics records (SMF record types 118 and 119, FTP-related subtypes only)
- CSSMTP configuration records (SMF record type 119 subtype 48)
- Security audit event records (SMF record type 83, subtype 5 and 6)
- NFS audit statistics records (SMF record type 42 subtype 26)

`UNIX_FILENAME` is a repeated field for RACF which combines information from extended-length relocate sections 263, 264, 270, 271, and 298. If a `CKFREEZE` file is present, the information in it is consulted for translating file identifiers into full path names and the like.

With FACCESS events, the new file name precedes the old file name.

With SMF record types 92, 118, and 119 (except type 119 subtype 48), the UNIX_FILENAME field contains a single file name at most.

A CKFREEZE file contains data from a particular point in time. For example, if a RENAMEF event is enriched based on a CKFREEZE system snapshot that was taken slightly before the event, the data in the UNIX_FILENAME field will probably yield the *old* file name. UNIX_FILENAME is the last qualifier of UNIX_PATHNAME.

The default output format for this field shows the first 256 characters of the file name which can exceed available space on the output line. To include the full file name, use the following format specification in CARLa scripts: unix_filename(0,wrap).

UNIX_FILETYPE

This field is found in RACF processing records (SMF record type 80) that contain a file audit ID, NFS audit statistics records (SMF record type 42 subtype 26), and in UNIX File System activity records (SMF record type 92) containing an inode. It may contain the UNIX file type (see "TYPE" on page 1489). This is determined via a lookup to the UNIX file system. The field is empty if no CKFREEZE is present or if the CKFREEZE does not contain the required information. File audit ids in RACF processing records are contained in RACF_SECTION(264) and RACF_SECTION(271). This is not a repeated field; if both file audit id sections are present, the first match against the UNIX file system determines the result. Currently the file audit id is only available for files in an HFS. See also UNIX_PATHNAME.

UNIX_FUNCTION

This numeric field is only found in RACF processing records (SMF record type 80) , NFS audit statistics records (SMF record type 42 subtype 26), and in ACF2 OMVS records. The UNIX_FUNCTION field represents the USS Audit Function Code (found in RACF_SECTION(256) with RACF and found in SMFOEAFC with ACF2). The field one of the indications tabulated below of the operation which led to the creation of the SMF record. The UNIX_FUNCTION field can be compared with numbers and with indications (non-quoted strings), as in UNIX_FUNCTION=(mount, DUB, 19, '1A'x). Indications AFC_*nnn* cannot be used in comparisons. Use numbers *nnn* instead. For example, use 0 instead of AFC_0.

Table 530. SMF record UNIX_FUNCTION field - indicator values

Indication	Value	Description
access	1	Check file accessibility
acc_disc	97	Discard access rights
acc_recv	96	Receive access rights
acc_send	95	Send access rights
authcheck	94	Authority check
bind	91	Bind a name to a socket
chattr	59	Change file attributes
chaudit_a	37	Change auditor audit options
chaudit_u	2	Change user audit options
chdir	3	Change current working directory
chmod	4	Change file modes

Table 530. SMF record UNIX_FUNCTION field - indicator values (continued)

Indication	Value	Description
chmount	109	Change mount (with the NOSETUID operand)
chmount_setuid	110	Change mount (using the SETUID operand)
chown	5	Change owner and group of file
chroot	88	Change root directory
console	99	Console communication service
dub	6	Initialize a process
eaccess	113	Check file access for effective IDs
exec	7	Execute a file
fchattr	60	Change file attributes for open file
fchaudit_a	38	Change auditor audit options when file is open
fchaudit_u	8	Change user audit options when file is open
fchdir	87	Change working directory
fchmod	9	Change file modes when file is open
fchown	10	Change owner and group of file when open
getcwd	11	Get current working directory
getmnt	42	Get mount entry
getpsent	12	Get process entry
ioctl	41	Get path name
kill	13	Signal a process
lchattr	116	Change attributes of file, directory, or symbolic link
lchown	79	Change owner and group of a symbolic link
link	14	Link to a file
login	104	__LOGIN system call
lookup	39	Path name resolution
lstat	15	Get file status; do not resolve ending symlink
mkdir	16	Make a directory
mknod	17	Make a file node
mount	18	Mount a file system (using the NOSETUID operand)
mount_na	118	Mount no audit
mount_setuid	105	Mount a file system (using the SETUID operand)
mount_u	119	User mount
mount_una	120	User mount no audit
msgctl	62	Message control
msgget	63	Message obtain
msgrcv	64	Message receive
msgsnd	65	Message send
newgrp	98	Newgrp shell utility
nice	84	Change priority of a process
open	19	Open a file
opendir	20	Open a directory

Table 530. SMF record UNIX_FUNCTION field - indicator values (continued)

Indication	Value	Description
password	78	Verify password
pathconf	21	Get configurable path name variables
pfsctl	81	Control function for the physical file system
poe	115	Provide port of entry identifier
ptrace	22	Debug a process
quiesce	43	Quiesce a file system (with the NOSETUID operand)
quiesce_setuid	107	Quiesce a file system (using the SETUID operand)
readlink	23	Read a symbolic link
realpath	89	Resolve path name
remove	74	Remove
rename	24	Rename a file
rmdir	25	Remove a directory
semctl	66	Semaphore control
semget	67	Get set of semaphores
semop	68	Semaphore operations
serv_init	100	WLM service Console communication service
setegid	26	Set effective GID
seteuid	27	Set effective UID
setfacl	111	Set, remove, or change ACLs
setfsecl	114	Set file seclabel
setgid	28	Set real/saved and/or effective GID
setpriority	83	Set process scheduling priority
setregid	71	Set real and/or effective GID
setreuid	85	Set real and/or effective UID
setrlimit	82	Set maximum resource consumption
setuid	29	Set real/saved and/or effective UID
set_gid	77	Set supplementary groups
set_mode	75	Set mode
set_msgqb	76	Set message queue maximum bytes
shmat	69	Shared memory attach
shmctl	70	Shared memory control
shmget	72	Shared memory get
shutdown_reg	112	USS shutdown registration
sigaction	50	Change Osigset action
socket	92	Create an endpoint for communication
spawn	101	Spawn
stat	30	Get file status
statvfs	90	Get file system information
swap_serv	102	Swap services
symlink	31	Create a symbolic link

Table 530. SMF record UNIX_FUNCTION field - indicator values (continued)

Indication	Value	Description
thlmt	61	Set thread limit
thread_sec	93	Thread level security
truncate	80	Truncate a file
ttyname	40	Get path name of terminal
unavailable	117	Audit function code not available
undub_exit	35	Terminate a process
unlink	32	Remove directory entries (Delete a file)
unmount	33	Unmount a file system (with the NOSETUID operand)
unmount_setuid	106	Unmount a file system (using the SETUID operand)
unmount_u	121	User unmount
unmount_una	122	User unmount no audit
unquiesce	44	Unquiesce a file system (with the NOSETUID operand)
unquiesce_setuid	108	Unquiesce a file system (using the SETUID operand)
utime	34	Set file access/modification times
vcreate	51	Server create
vlink	55	Server link
vlookup	47	Server lookup
vmakedir	52	Server make directory
vreaddir	49	Server read directory
vreadwrite	48	Server read write
vregister	45	Server registration
vremove	57	Server remove
vremovedir	56	Server remove directory
vrename	58	Server rename
vresolvepn	46	Server resolve path name
vsetattr	54	Server set file attributes
vsymlink	53	Server symbolic link
wgetipc	73	Query IPC status
wlmc	103	WLM C and C++
write	36	Write to a file (Clear setid bits)
writev	86	Write on a file

UNIX_PATHNAME

UNIX_PATHNAME shows the path name of the file or directory to which access was requested. The field is supported in the following record types:

- RACF processing records (SMF record type 80)
- OpenMVS File System activity records (SMF records type 92)
- CSSMTP configuration records (SMF record type 119 subtype 48)
- NFS audit statistics records (SMF record type 42 subtype 26)

UNIX_PATHNAME is a repeated field for RACF which combines information from extended-length relocate sections 263, 264, 270, 271, and 298. With record

type 80 and with ACF2 OMVS records, it can have 1 or 2 entries of at most 1023 characters each. With RENAMEF events, the first entry is the old path name and the second entry is the new path name. On the other hand, with FACCESS events, the new path name precedes the old path name. With record types 92, 118, and 119 CSSMTP configuration records (SMF record type 119 subtype 48), the UNIX_PATHNAME field contains a single path name at most. If a CKFREEZE is present, then with RACF but not with ACF2, the information in it is consulted for translating file identifiers into full path names and the like. Note that a CKFREEZE denotes a particular point in time; e.g., if a RENAMEF event is enriched based on a CKFREEZE system snapshot from slightly before the event, this will probably yield the full *old* path name. The last qualifier of UNIX_PATHNAME is UNIX_FILENAME. For ACF2 OMVS records, the path names are usually relative.

The default output format for this field shows the first 256 characters of the file name are shown in the output which can exceed available space on the output line. To include the full path name, use the following format specification in CARLa scripts: `unix_pathname(0,wrap)`

UNIX_PROGRAM

UNIX program name. This field contains the first 16 bytes of the UNIX program path name run as a substep (through the UNIX exec service) within a job step. It is only found in SMF record type 30.

USER, USERID

SAF userid. This field is found in the following record types:

- DFSORT records (SMF record type 16)
- Job Initiation and Accounting records (SMF record types 20, 30 and 32)
- RACF processing and R_auditx records (SMF record types 80 and 83)
- NFS audit statistics records (SMF record type 42 subtype 26)
- z/OS Firewall Technologies records (SMF record type 109)
- CICS records (SMF record type 110)

  For CICS subrecords, USER returns the RACF userid that performed the CICS transaction.
- HSM function statistics records
- DB2 records (SMF record type 102) with subtypes/IFCids 83, 87, 140, 142, 269, and 314 if non-blank and non-null.
- CSSMTP client records (SMF record type 119) with subtypes 48, 50, and 51 if non-blank and non-null.

It is derived using the job tag system for data set and ICF catalog activity records (SMF record types 14, 15, 17, 18, 60, 61, 62, 64, 65 and 66).

Note: Some HSM function statistics records may contain the user id ****HSM***** or ***H*S*M*** (the second pseudo-userid starts with a leading zero). These are not SAF userids, but pseudo-userids generated by the HSM software.

To select a userid that is the target of a RACF command, use one of the RACFCMD_USER, RESOURCE or PROFILE fields instead. To select a userid that is the target of an ACF2 command, use ACF2_RULEKEY instead. The USER field describes the command-issuing user, not the target user.

UTOKEN

A string describing the contents of the User Security Token included in the following record types:

- All RACF processing records (SMF record types 80 and 83 subtype 1).
- In several DB2 subtypes (SMF record type 102).
- In CSSMTP subtypes (SMF type 119 subtype 48 records).

Because UTOKEN contains many fields, many of which need not be set, the output has the format `field1: value1; field2: value2`.

This field can only be used for output; to select all records with a UTOKEN field, use SELECT RELOCATE=53. To select on values contained in the UTOKEN field, use the following derived fields:

```
UTOKEN_FLAGS, UTOKEN_SESSION, UTOKEN_POE
UTOKEN_POECLASS, UTOKEN_SUSER, UTOKEN_SGROUP
UTOKEN_SNODE and UTOKEN_XNODE
```

Note: The values printed by the UTOKEN field are subject to change. Do not write applications that are dependent on the output of this field.

UTOKEN_FLAGS

This field describes the flags found in the User Security Token, which is included in the following record types:

- All RACF processing records (SMF record types 80 and 83 subtype 1).
- In several DB2 subtypes (SMF record type 102).
- In CSSMTP subtypes (SMF type 119 subtype 48 records).

It can be used for SELECT/EXCLUDE processing and for output. However, in most cases the UTOKEN field is more convenient for output.

Because many flags can be set at the same time, the default output of this field is in a condensed format; full output split into several lines can be requested using the EXPLODE output modifier, for example, UTOKEN_FLAGS(EXPLODE). The following table lists the UTOKEN_FLAGS values that can be used for SELECT/EXCLUDE processing; the condensed output; the exploded output; and the meaning.

Table 531. SMF record UTOKEN_FLAGS field - values for output processing

SELECT/EXCLUDE	Condensed	Exploded	Meaning
DEFAULT	... .D. ...	Default	Default user
ENCRYPTED	... ... C..	Encrypted	Token is encrypted
ERROR	... .E	Error	Token in error
LOG, LOGUSER	..L	Log user	User is logged (UAUDIT)
NJEUNKNOWN	... .N. ...	NJE Unknown	NJE unknown user
PRE19	... .<.	Pre 1.9	Created by pre 1.9 call
PRIVILEGED	P..	Privileged	Privileged user
PROPAGATE	... P.. ...	Propagate	Propagated ID values
REMOTE	... ..R ...	Remote	Remote job
SPECIAL	.S.	Special	User has special attribute
SURROGATE	... S.. ...	Surrogate	Surrogate job
TRUSTED	T..	Trusted	Trusted user
UNDEFINED	... .U. ...	Undefined	Undefined user

Table 531. SMF record UTOKEN_FLAGS field - values for output processing (continued)

SELECT/EXCLUDE	Condensed	Exploded	Meaning
WRITEDOWN	... ...W ...	WriteDown	MLS WriteDown

For SELECT/EXCLUDE processing, a list of values may be specified, e.g. SELECT UTOKEN_FLAGS=(SURROGATE,REMOTE,PROPAGATE). Only the =, <>, and ¬= relational operators can be used. With the = relational operator, the SELECT/EXCLUDE expression is true if any record's UTOKEN flags type matches any of the values specified; with the <> and ¬= relational operators, the SELECT/EXCLUDE expression is true if all of the record's UTOKEN flags types match none of the values specified.

Notes:

1. The condensed output is split into three parts: user attributes, job attributes, and token attributes.
2. The values printed by the UTOKEN_FLAGS field are subject to change. Do not write applications that are dependent on the output of this field.

UTOKEN_POE

This text field describes the Port-Of-Entry contained in the User Security token, which is included in the following record types:

- All RACF processing records (SMF record types 80 and 83 subtype 1).
- In several DB2 subtypes (SMF record type 102).
- In CSSMTP subtypes (SMF type 119 subtype 48 records).

UTOKEN_POE can be used for SELECT/EXCLUDE processing and for output. However, in most cases the UTOKEN field is more convenient for output. The Port-Of-Entry class is described with the UTOKEN_POECLASS field.

UTOKEN_POECLASS

This field describes the Port-Of-Entry class type contained in the User Security token, which is included in the folllowing record types:

- All RACF processing records (SMF record types 80 and 83 subtype 1).
- In several DB2 subtypes (SMF record type 102).
- In CSSMTP subtypes (SMF type 119 subtype 48 records).

It can be used for SELECT/EXCLUDE processing and for output. However, in most cases the UTOKEN field is more convenient for output. The Port-Of-Entry is described with the UTOKEN_POE field.

UTOKEN_POECLASS values are:

APPCPORT
CONSOLE
JESINPUT
SERVAUTH
TERMINAL

For SELECT/EXCLUDE processing, a list of values may be specified, e.g. SELECT UTOKEN_POECLASS=(TERMINAL,JESINPUT). The numeric value of the Port-Of-Entry class can be specified as well. Only the =, <>, and ¬= relational operators can be used. With the = relational operator, the SELECT/EXCLUDE expression is true if the record's Port-Of-Entry class

matches any of the values specified; with the <> and ¬= relational operators, the SELECT/EXCLUDE expression is true if the record's Port-Of-Entry class matches none of the values specified.

UTOKEN_POE_NETWORK

This text field describes the Port-Of-Entry Network contained in the User Security token, which is included in the following record types.

- All RACF processing records (SMF record types 80 and 83 subtype 1).
- In several DB2 subtypes (SMF record type 102).
- In CSSMTP subtypes (SMF type 119 subtype 48 records).

It can be used for SELECT/EXCLUDE processing and for output; however, in most cases the UTOKEN field will be more convenient for output.

UTOKEN_SESSION

This field describes the session type contained in the User Security token, which is included in the following record types.

- All RACF processing records (SMF record types 80 and 83 subtype 1).
- In several DB2 subtypes (SMF record type 102).
- In CSSMTP subtypes (SMF type 119 subtype 48 records).

It can be used for SELECT/EXCLUDE processing and for output; however, in most cases the UTOKEN field is more convenient for output.

The following table lists the UTOKEN_SESSION values that can be used for SELECT/EXCLUDE processing; the output values; and the meaning (XBM=eXternal Batch Monitor; NJE=Network Job Entry; RJE=Remote Job Entry).

Table 532. SMF record UTOKEN_SESSION field - values for output processing

SELECT/EXCLUDE	Output	Meaning
APPC	APPC	APPC
COMMAND	Command	Command
CONSOLE	Console	Console operator
EXTJOB EXTRDRJOB	Extrdr job	External reader job
EXTXBM EXTRDRXBM	Extrdr XBM	External reader XBM
INTJOB INTRDRJOB	Intrdr job	Internal reader job
INTXBM INTRDRXBM	Intrdr XBM	Internal reader XBM
MOUNT	Mount	Mount
NJEJOB	NJE job	NJE job
NJEOPER	NJE operator	NJE operator
NJESYSOUT	NJE sysout	NJE sysout
NJEUNKNOWN	NJE unknown user	NJE unknown user
NJEXBM	NJE XBM	NJE XBM
OMVSSRV OMVS	OMVSSRV	OMVSSRV
RJEJOB	RJE job	RJE job
RJEOPER	RJE operator	RJE operator

Table 532. SMF record UTOKEN_SESSION field - values for output processing (continued)

SELECT/EXCLUDE	Output	Meaning
RJEXBM	RJE XBM	RJE XBM
STC	STC	Started procedure
SYSTEM	System	System address space
TSO	TSO	TSO logon

For SELECT/EXCLUDE processing, a list of values may be specified, e.g. SELECT UTOKEN_SESSION=(NJEXBM,NJESYSOUT,NJEJOB). Only the =, <>, and ¬= relational operators can be used. With the = relational operator, the SELECT/EXCLUDE expression is true if the record's session type matches any of the values specified; with the <> and ¬= relational operators, the SELECT/EXCLUDE expression is true if the record's session types matches none of the values specified.

UTOKEN_SGROUP, UTOKEN_SGRP

This text field describes the connect group of the submitting user contained in the User Security token, which is included in the following record types.

- All RACF processing records (SMF record types 80 and 83 subtype 1).
- In several DB2 subtypes (SMF record type 102).
- In CSSMTP subtypes (SMF type 119 subtype 48 records).

It can be used for SELECT/EXCLUDE processing and for output; however, in most cases the UTOKEN field is more convenient for output. See also the UTOKEN_SUSER, UTOKEN_SNODE, and UTOKEN_XNODE fields.

UTOKEN_SNODE

This text field describes the submitting node contained in the User Security token, which is included in the following record types.

- All RACF processing records (SMF record types 80 and 83 subtype 1).
- In several DB2 subtypes (SMF record type 102).
- In CSSMTP subtypes (SMF type 119 subtype 48 records).

It can be used for SELECT/EXCLUDE processing and for output; however, in most cases the UTOKEN field is more convenient for output. See also the UTOKEN_SGROUP, UTOKEN_SUSER, and UTOKEN_XNODE fields.

UTOKEN_SUSER, UTOKEN_SUSR

This text field describes the submitting user contained in the User Security token, which is included in the following record types.

- All RACF processing records (SMF record types 80 and 83 subtype 1).
- In several DB2 subtypes (SMF record type 102).
- In CSSMTP subtypes (SMF type 119 subtype 48 records).

It can be used for SELECT/EXCLUDE processing and for output; however, in most cases the UTOKEN field is more convenient for output. See also the UTOKEN_SGROUP, UTOKEN_SNODE, and UTOKEN_XNODE fields.

UTOKEN_XNODE

This text field describes the execution node contained in the User Security token, which is included in the following record types.

- All RACF processing records (SMF record types 80 and 83 subtype 1).
- In several DB2 subtypes (SMF record type 102).

- In CSSMTP subtypes (SMF type 119 subtype 48 records).

It can be used for SELECT/EXCLUDE processing and for output; however, in most cases the UTOKEN field is more convenient for output. See also the UTOKEN_SGROUP, UTOKEN_SUSER, and UTOKEN_SNODE fields.

VOLSER, VOLUME

Volume serial. This field is found in most data set and volume-related records (SMF record types 14, 15, 17, 18, 19, 21, 36, 42, 60, 62, 64 and 69), HSM function statistics records, RACF processing records (SMF record types 80 and 83) for class=DATASET, ACF2 data set use records, and TSS processing records (SMF record type 80) for class=DATASET.

Note: VOLSER is a repeated field. In the current version of Security zSecure, this repeated field may contain duplicate volume serials for some record types.

VOLSER_OR_SMS

Volume serial or, if the volume is SMS-managed, *SMS*. This field is found in most data set and volume-related records (SMF record types 14, 15, 17, 18, 19, 21, 36, 60, 62, 64 and 69), HSM function statistics records, RACF processing records (SMF record types 80 and 83) for class=DATASET, ACF2 data set use records, and TSS processing records (SMF record type 80) for class=DATASET.

Note: VOLSER_OR_SMS is a repeated field. In the current version of Security zSecure, this repeated field may contain duplicate volume serials for some record types.

VTAMNET_IS_REMOTE

VTAMNET_IS_REMOTE is a flag field that indicates whether the VTAM network ID associated with a CICS transaction is from a remote network. The value is TRUE if it is remote. If the VTAM net ID information is not available, this field is not reported.This field is supported on CICS monitoring subrecords.

VTAMNETID

For CICS monitoring performance sub records, this field returns the name by which the network unit-of-work ID is known within the originating system. This name is assigned at transaction attach time using either a STCK-derived token created by the originating system, or the network unit-of-work ID passed as part of an IRC (MRO) or ISC (APPC) attach function management header (FMH).

WEEKDAY

Day of the week the record was written. For SELECT/EXCLUDE processing, either specify the weekday name in full or use the first three characters of the weekday name (for example, SUNDAY or SUN for Sunday). The default output is also three characters long; specify an overriding output length of 9 characters to output the full weekday. This field is found in all SMF record types. For SELECT/EXCLUDE processing, a range of weekdays separated by a colon (:) is allowed, as indicated in the following examples. A range of MON:WED is inclusive, for example, Monday, Tuesday, and Wednesday. For use with the relational operators <, <=, >, and >=, the sort order has been defined as Sunday < Monday < ... < Saturday.

```
SELECT WEEKDAY=MON                      /* One day */
SELECT WEEKDAY=(MON, FRI)               /* Two days */
SELECT WEEKDAY>=TUE WEEKDAY<=SAT        /* Day range */
```

```
SELECT WEEKDAY=TUE:SAT                    /* Day range */
SELECT WEEKDAY>=FRI OR WEEKDAY<=MON       /* Day range */
SELECT WEEKDAY=FRI:MON                    /* Day range */
```

YEAR

Year the record was written. For SELECT/EXCLUDE processing, a YEAR value in the range 0 to 99 is only allowed if you suppress message CKR051I and then implies a year the 20th century. For example, YEAR=94 is equal to YEAR=1994. This field is found in all SMF record types. For SELECT/EXCLUDE processing, a range of years separated by a colon (:) is allowed, as indicated in the following examples.

```
SELECT YEAR=1994                          /* One year */
SELECT YEAR=(1994, 1988, 1989)            /* Three years */
SELECT YEAR>=1992 YEAR<=1996              /* Year range */
SELECT YEAR=1992:1996                     /* Year range */
```

Tables of fields and record types

SMF records contain various types of event information depending on the source of the events. For information on the fields that apply to different types of SMF records, see the following topics:

Fields common to all record types

Most fields are only found in the predefined SMF record types; the following list includes the common fields found in all record types. The following table documents the fields common to all record types.

Fields common to all SMF record types

DATE
FIELDVAL
MONTH
MONTHDAY
RECNO
RECORDDESC
RECORDLENGTH
SMFDD
SUBTYPE
SYSTEM
SYSTYPE
TIME
TYPE
WEEKDAY
YEAR

Note: The SUBTYPE field is found in all records that support subtypes. This field is defined in the SMF record header.

Supported record types

Table 533 on page 1389 shows all record types with a short description of their content. It also shows whether this stock description is the only thing present in the RECORDDESC field (`Stock=Y`) or if it contains more data. The details column indicates whether there are more fields present than just the common fields. See "Record types vs. field names" on page 1391 for an exact list of extra fields.

Table 533. SMF records - supported record types

SMF record type	Description	Details	RECORDDESC field only provides stock description (Y) or contains additional information (N)
0	IPL		Y
2	Dump Header		Y
3	Dump Trailer		Y
4	Step Termination	Y	Y
5	Job Termination	Y	Y
6	Output Writer or PSF	Y	Y
7	Data Lost		
8	I/O Configuration		Y
9	VARY Device ONLINE		
10	Allocation Recovery	Y	Y
11	VARY Device OFFLINE		
14	INPUT or RDBACK Data Set Activity	Y	
15	OUTPUT, UPDATE, INOUT, or OUTIN Data Set Activity	Y	
16	DFSORT Statistics	Y	Y
17	Scratch Data Set Status	Y	
18	Rename Data Set Status	Y	
19	Direct Access Volume	Y	Y
20	Job Initiation	Y	
21	Error Statistics by Volume	Y	
22	Configuration		Y
23	SMF Status		Y
24	JES2 Spool Offload	Y	Y
25	JES3 Device Allocation	Y	Y
26	JES2 or JES3 Job Purge	Y	
28	NPM Statistics		Y
30	Common Address Space Work	Y	
31	TIOC Initialization		Y
32	TSO/E User Work Accounting	Y	
33	APPC/MVS TP Accounting	Y	
34	TS-Step Termination	Y	
35	LOGOFF	Y	
36	ICF Catalog	Y	Y
37	Netview Hardware Monitor		Y
39	Netview (NLDM) Response Time		Y

14. HSM Daily/Volume Statistics: The SMF record number of this record type is installation-dependent.
15. Record type 81 is supported through defined variables in CARLa member CKAS0081.
16. Record type 89 is supported through defined variables in CARLa member CKAS0089.
17. Record type 90 is supported through defined variables in CARLa member CKAS0090.
18. HSM function statistics: The SMF record number of this record type is installation-dependent.
19. ACF2: The SMF record number of this record type is installation-dependent, default is 230.

Table 533. SMF records - supported record types (continued)

SMF record type	Description	Details	RECORDDESC field only provides stock description (Y) or contains additional information (N)
40	Dynamic DD	Y	Y
41	DIV ACCESS/UNACCESS	Y	Y
42	DFSMS Statistics and Configuration		Y
43	JES2 or JES3 Start		Y
45	JES2 Withdrawal or JES3 Stop		Y
47	JES2 or JES3 SIGNON/Start Line/LOGON		Y
48	JES2 or JES3 SIGNOFF/Stop Line/LOGOFF		Y
49	JES2 or JES3 Integrity		Y
50	ACF/VTAM Tuning Statistics		Y
52	JES2 LOGON/Start Line		Y
53	JES2 LOGOFF/Stop Line		Y
54	JES2 Integrity		Y
55	JES2 Network SIGNON		Y
56	JES2 Network Integrity		Y
57	JES2 or JES3 Network Transmission		Y
58	JES2 Network SIGNOFF		Y
59	MVS/BDT File-to-File Transmission		Y

Record types vs. field names

This section lists the predefined SMF record types and the fields found in those records. The list includes only those record types have fields other than the

common and RECORDDESC fields, and only those fields limited to some SMF record types. The fields that are only found in RACF or ACF2 processing records are not included; see the next tables for the fields available in RACF and ACF2 records.[20]

For the list of fields organized by SMF record types, see the following topics:

- Table 534 on page 1393 for SMF record types 1- 26
- Table 535 on page 1394 for SMF record types 30 - 65
- Table 536 on page 1395 for SMF record types 66 - 119

20. HSM Func Stats: The SMF record number of this record type is installation-dependent.

Table 534. Predefined SMF record types: fields available by type - SMF records 1-26

Fields found only in CICS records

zSecure can report on information contained in SMF audit trail records related to the CICS monitoring performance subrecords (SMF record type 110, subtype 1, subclass 3)

Table 537 lists the fields that contain the information extracted from the CICS monitoring performance records. These records do not include the common fields found in all record types. For information on those fields, see "Fields common to all record types" on page 1388.

Table 537. CICS monitoring records

Field	Field description available at ...
CICS_MONITOR_CLASS	1278
CICS_PERFORMANCE_DATA	1279
CICS_SPECIFIC_APPL	1279
CICS_TERM	1279
CICS_TTYPE	1279
ELAPSED	1290
EVENT_DATETIME	1305
SUBRECORD	1350
SUBRECORDNO	1351
TRANSACTION	1373
VTAMNET_IS_REMOTE	1386
VTAMNETID	1386

Fields found only in CSSMTP records

zSecure can report on information contained in SMF type 119, subtype 48-52 records produced by the Communications Server SMTP client (CSSMTP). Information from the following kinds of records can be shown:

- CSSMTP configuration records (SMF record type 119, subtype 48)
- CSSMTP connection records (SMF record type 119, subtype 49)
- CSSMTP mail records (SMF record type 119, subtype 50)
- CSSMTP spool records (SMF record type 119, subtype 51)
- CSSMTP statistics records (SMF record type 119, subtype 52)

The CARLa fields associated with these records are described in "SMF: SMF records" on page 1276. Most of these fields are only found in CSSMTP SMF records. The name of each field begins with the character string `CSSMTP`.

Fields found only in DB2 records

zSecure can report on information contained in SMF audit trail records related to the following DB2 record types:

- DB2 Statistics records (SMF record type 100)

- DB2 Accounting records (SMF record type 101)
- DB2 Performance records (SMF record type 102)

Table 538 lists the fields that contain the information extracted from the DB2 audit records. These records do not include the common fields found in all record types that are described earlier. (See "Fields common to all record types" on page 1388.)

Table 538. DB2 SMF records - field descriptions

Field	Field description available at ...
DB2_APPL_USERID	1286
DB2_AUTHID	1286
DB2_COMMAND	1287
DB2_CONNECTION	1287
DB2_CONTEXT	1287
DB2_ENDUSER_USERID	1288
DB2_OBJECT	1288
DB2_OBJECT_TYPE	1288
DB2_ORIGINAL_OPERATOR	1288
DB2_PLAN	1288
DB2_ROLE	1288
DB2_SECAUTHID	1289
DB2_SQLID	1289

Fields found only in IP stack configuration records

The fields found only in the SMF records for TCP/IP configuration information are listed in the SMF field description chapter. These fields begin with the character string IP.

The TCP/IP configuration record types, common fields, and field descriptions are also documented in the IP newlists in "IP: Profile information for TCP/IP configuration" on page 1054. In the IP NEWLIST field descriptions, the fields are the same as the SMF fields, but they have different names. The IP NEWLIST field names are not preceded by the IP configuration information type. For example, the SMF field for IP_RULE_SRCPRT is equivalent to the SRCPRT field in the IP_RULE NEWLIST.

Fields found only in Omegamon security audit records

zSecure can report on information contained in SMF audit trail records related to Omegamon commands. These records are generated from Omegamon Classic address spaces (z/OS, DB/2, IMS, CICS) that have been configured for auditing. Table 539 on page 1399 lists the fields that contain the information extracted from the Omegamon audit records.

The common fields found in all record types, and the fields that are found in one or more record types other than RACF processing records (except for the R_auditx records), are not included in this table. See "Fields common to all record types" on page 1388 and see the previous tables. The following fields contain the information extracted from these records.

Table 539. Omegamon audit records - field descriptions

Field	Field description available at ...
OMCMD_NAME	1336.
OMCMD_ALLOWED	1336.
OMCMD_TEXT	1336.
OMCMD_TYPE	1336.

You can also generate pre-defined reports for Omegamon auditing records from the Events menu (EV.6). For more information, see "Reporting on Omegamon events (EV.6)" on page 572.

Fields for User Security Token

The following fields for User Security Token information are documented in the SMF section. These fields document the contents of the security token and information regarding the Port of Entry. These fields apply to the following record types: RACF processing records (SMF record types 80 and 83 subtype 1), DB2 subtypes (SMF record type 102), and CSSMTP client records (SMF record type 119) with subtype 48.

- "UTOKEN" on page 1381
- "UTOKEN_POE" on page 1383
- "UTOKEN_POECLASS" on page 1383
- "UTOKEN_POE_NETWORK" on page 1384
- "UTOKEN_SESSION" on page 1384
- "UTOKEN_SGROUP" on page 1385
- "UTOKEN_SNODE" on page 1385
- "UTOKEN_SUSER" on page 1385
- "UTOKEN_XNODE" on page 1385

Fields found in RACF processing records

The following table lists the fields that are found in RACF processing records (SMF record types 80 and 83 subtype 1). The 'common' fields found in all record types, and the fields that are found in one or more record types other than RACF processing records (except for the R_auditx records), are not included in this table. See the other tables.

Table 540. SMF RACF processing records - field descriptions

Field name	Meaning	Event types
ACCESS	Allowed access	ACCESS
APPL	Application name	RACINIT ACCESS
DESCRIPTOR	Record descriptor	all
EVENT	Event code	all
EVENTDESC	Description of event	all
EVENTQUAL	Event qualifier code	all
KERB_NAME	Kerberos principal name	all
KERB_SOURCE	Kerberos login request source	all
KERB_STATUS	Kerberos KDC status code.	all

Table 540. SMF RACF processing records - field descriptions (continued)

Field name	Meaning	Event types
LOGSTR	Log string	ALLSVC GENERAL
OWNER	Profile owner	all
PKCS11_TOKEN	Token name	RACDCERT
RACFAUTH	RACF authority used	all
RACFCMD	RACF command string	ALLCOMMAND
RACFCMD_AUTH	Authority specified in a RACF command	ADDUSER ALTUSER CONNECT
RACFCMD_GROUP	Target group of RACF command	ADDGROUP ALTGROUP CONNECT DELGROUP PERMIT REMOVE
RACFCMD_KEYWORDS	Keywords used in a RACF command	ALLCOMMAND
RACFCMD_KEYWORDS_EFF	Effective keywords used in a RACF command	ALLCOMMAND
RACFCMD_OWNER	New owner specified in a RACF command	ADDGROUP ADDSD, ADDUSER ALTDSD ALTGROUP , ALTUSER CONNECT RALTER RDEFINE REMOVE
RACF_SECTION	User-defined fields	all
RACFCMD_USER	Target user of RACF command	ADDUSER ALTUSER CONNECT DELUSER PASSWORD PERMIT REMOVE
REASON	Reason to log the event	all
RELOCATE	List of relocate section codes	all
RTOKEN	Resource security token	ACCESS
RTOKEN_FLAGS	Flags from resource security token	ACCESS
SECLABEL	User's security label	ACCESS
UNIX_ACCESS_ALLOWED	Access allowed	UNIX-related
UNIX_ACCESS_INTENT	Access intent	UNIX-related
UNIX_ACCESS_ORIGIN	Access origin	UNIX-related
UNIX_ACCESS_USED	Access used	UNIX-related
UNIX_FILENAME	File name	UNIX-related
UNIX_FUNCTION	Audit function code	UNIX-related
UTOKEN	User's security token	all

Table 540. SMF RACF processing records - field descriptions (continued)

Field name	Meaning	Event types
UTOKEN_FLAGS	Flags from user security token	all
UTOKEN_POE	Port-Of-Entry	all
UTOKEN_POECLASS	Port-Of-Entry class	all
UTOKEN_POE_NETWORK	Port Of Entry network	all
UTOKEN_SESSION	Session type	all
UTOKEN_SGROUP	Connect group of submitting user	all
UTOKEN_SNODE	Submitting node	all
UTOKEN_SUSER	Submitting user	all
UTOKEN_XNODE	Execution node	all

Fields found in R_auditx records

The R_auditx service is used to create audit records for Enterprise and Identity Mapping (EIM), subtype 2 events.

The following table lists the fields that are found in these records. The common fields found in all record types are not included in this table. (See "Fields common to all record types" on page 1388.)

Table 541. SMF R_auditx records - Fields found in Enterprise Identity Mapping (EIM) Event 2

Field name	Applications
APPL	All
CERTIFICATE_ISSUER	All
CERTIFICATE_SUBJECT	All
CLASS	All
DESCRIPTOR	All
DSTIP	EIM
DSTPORT	EIM
EVENT	All
EVENTDESC	All
EVENTQUAL	All
GROUP	All
JOBID	All
JOBNAME	All
JOBTAG	All
LOGSTR	All
PROFILE	All
RACFAUTH	All
REASON	All
RELOCATE	All
RESOURCE	All
SECLABEL	All

Table 541. SMF R_auditx records - Fields found in Enterprise Identity Mapping (EIM) Event 2 (continued)

Field name	Applications
SMFUSERID	All
TERMINAL	All
USER	All

Fields found only in security audit records (SMF record 83, subtype 4, 5 and 6)

Table 542 lists the fields that are only found in security audit records generated by the following applications:

- IBM Tivoli Key Lifecycle Manager (SMF record type 83, subtype 6)
- IBM Websphere Application Server, version 7.0 and later (SMF record type 83, subtype 5)
- Linux events logged remotely by the Linux audispd plug-in (daemon) or .JZOS toolkit

This information does not include common fields found in all record types or the fields that are found in one or more record types other than the audit security records. See "Fields common to all record types" on page 1388 and Table 534 on page 1393.

Table 542. SMF record types - fields only found in security audit records (SMF record type 83, subtype 5 and 6)

Field name	Meaning	Record subtype
R_ACCESS	Allowed access	5- Websphere Application Server events
R_ACTION	Action type	ACCESS events
R_EVENT	Event type	6- Tivoli Key Lifecycle Manager events Websphere Application Server events
R_INTENT	Intended access	6- Tivoli Key Lifecycle Manager events Websphere Application Server events
RACF_LINK_AUDIT	Serial number for the Linux Audit record which is shared by all records created from the same event.	4 - zLinux events
RACF_LINK_EVENT	Serial number for a security audit event from a zLinux system.	4 - zLinux events
R_LOGDATA	Application-specific data for the event including all field names and values in a `fieldname=value` format.	4 - zLinux events
R_LOGRECORD	Native java log record	6 - Tivoli Key Lifecycle Manager events
R_MGMT_ATTR	Information about objects involved in operation	5 - Websphere Application Server events

Table 542. SMF record types - fields only found in security audit records (SMF record type 83, subtype 5 and 6) (continued)

Field name	Meaning	Record subtype
R_MGMT_CMD	Command performed	5 - Websphere Application Server events
R_MGMT_TYPE	Management operation type	5 - Websphere Application Server events
R_RESOURCE	Resource name in application context	5 - Tivoli Key Lifecycle Manager events Websphere Application Server events
R_RESULT	Event outcome	5 - Websphere Application Server events
R_ROLECHECK	Role checked	5 - Websphere Application Server events
R_ROLEGRANT	Role granted	5 - Websphere Application Server events
R_USER	User ID used for authentication or authorization	6 - Tivoli Key Lifecycle Manager events Websphere Application Server events
SRCHOST	Port number of remote host	5 - Websphere Application Server events

SMFOPT: SMF Subsystems

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The SMFOPT NEWLIST (NEWLIST TYPE=SMFOPT) provides information about the SMF subsystem in a MVS system. This NEWLIST generates one entry per SMF subsystem in an MVS system. Each entry is uniquely identified by the fields SYSTEM SUBSYS.

Field descriptions

The SMFOPT NEWLIST provides the following fields for reporting.

ACTIVE

For any SMF record type, this flag field indicates if the SMF record type is recorded for this SMF subsystem. This field is repeated and can be combined with the RECORD and DESC fields.

ACTREC, WRTREC

A repeat group giving a list of all active record types. Any active record type has ACTIVE=YES.

Note: When this field is combined with the ACTIVE or DESC fields, the entries do not line up correctly.

AUDITCONCERN

This field indicates the reason for the audit priority. Do not rely on the exact value of this field in your programs because the content might change. The

AUDITCONCERN field can contain one or more concerns separated by commas. The following audit concerns have currently been defined:

- RACF records suppressed

  RACF is active, and SMF record types 80 or 81 (or 83 if MLACTIVE is set) are suppressed for the subsystem. As a result, no RACF processing or status records are available. System system security events cannot be audited.

- Job start not recorded

  Job start records (SMF record type 20 and type 30, subtype 1) are suppressed. As a result, job starts cannot be audited. Note that RACF does *not* log job start events unless a security-related event occurred.

- Data loss not recorded

  SMF records can be lost in the system (the system-wide options NOBUFFSHALT and LASTDSHALT are not both set), and the subsystem does not record SMF type 7 (Data lost). If a data loss should occur, this is not logged; an auditor is not able to tell when SMF data were lost.

- Data set activity not recorded

  One or more types of data set activity records (record types 14-15, 17-18, 60-62, 64-67) are suppressed. Security zSecure is not able to analyze all data set activities.

- Interval recording not active

  Step interval records (SMF record type 30, subtypes 2 and 3) are not written for the subsystem. Accounting information for long-running jobs are lost if the system unexpectedly goes down.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 543. SMFOPT NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. The complex name can come from the ALLOC COMPLEX parameter or default to a system name.

DESC, DESCRIPTION

A string of up to 64 characters giving, for any SMF record type, a short description of the record type and subtype. This field is repeated and can be combined with the RECORD and ACTIVE fields.

DETAIL

A flag indicating whether detail recording is active. When detail recording is active (DETAIL=YES), SMF record types 30 and 32 contain additional information such as total CPU time used and EXCP counts for started tasks. If detail recording is inactive (DETAIL=NO), SMF record type 30 contains EXCP counts for TSO/E users and batch jobs only.

EXITCNT, EXITCOUNT

Number of SMF exits active for this subsystem. The exits can be listed with the ADDRESS and PROGRAM fields, or with NEWLIST TYPE=EXIT.

INACTREC, SUPREC

A repeat group giving a list of all inactive (suppressed) record types. Any inactive record type has ACTIVE=NO.

Note: When this field is combined with the ACTIVE or DESC fields, the entries do not line up correctly.

INTERVAL

The SMF recording interval in the format HH:MM:SS. If this value is blank, no interval records are written; any other value specifies the length of the interval in hours, minutes and seconds. At the end of each interval, SMF record types 30 and 32 are written to record accounting data for the past interval.

This field is output-only: it cannot be used in the SELECT and EXCLUDE commands.

PARTCNT, PARTCOUNT

The number of different SMF record types partially written, for example some subtypes are written, and some subtypes are suppressed.

PROGRAM

Indicates, for each exit, the program name of the exit as present in the in-storage SMF control blocks. This field is repeated and can be combined with the ADDRESS field. More information about the exit routine can be displayed with NEWLIST TYPE=EXIT (select APPL=SMF).

RECORD, REC

The type and subtype of an SMF record, in the format '**type**' or '**type-subtype**'. This field is repeated and can be combined with the ACTIVE and DESC fields.

SUBSYS

Name of the subsystem for which the SMF options are set. This name, when combined with the SYSTEM field, identifies an entry in this NEWLIST type.

The subsystem name can be SYS (for system-wide settings), one of the SMF-defined types STC and TSO, or an actual subsystem such as JES2. The NEWLIST TYPE=SUBSYS can be used to report on actual subsystems.

SUMMARY

A single line summarizing the SMF recording options, in the format `suppress n n:n n(s,s)`, `write n n:n n(s,s)` (with `n` record types, `s` record

subtypes, suppress none, write none, write all, or suppress all The suppress and write lines are both generated, and the shortest is taken.

SUPCNT, SUPCOUNT

The number of different SMF record types suppressed. Any record type that is suppressed has ACTIVE=NO.

SYSTEM

The name of the system. This is the SMF system ID. This name, when combined with the SUBSYS field, identifies an entry in this NEWLIST type. The field length is 8 characters to cater to VM systems.

WRTCNT, WRTCOUNT

The number of different SMF record types written. Any record type written has ACTIVE=YES.

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•		

The SPT NEWLIST (NEWLIST TYPE=SPT) provides information about the Started Procedure Table (SPT). It generates one entry per table entry per system. A unique key is SYSTEM ORDER. Unless otherwise stated, all fields can be used for SELECT and EXCLUDE processing as well as in the following output commands: LIST, SORTLIST, DISPLAY and SUMMARY.

The Started Procedure Table is loaded at IPL from module ICHRIN03. Inconsistencies in this table can be identified by running VERIFY STC.

Field descriptions

The SPT NEWLIST provides the following fields for reporting.

ATTR, AUTH

A string containing the started procedure attributes. If PRIVILEGED=YES, this field is set to *Privileged*. If TRUSTED=YES, this field is set to *Trusted*. Otherwise, the field is empty.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. The value is taken from the ALLOC COMPLEX parameter or default to a system name.

GROUP

The RACF group ID assigned to this started procedure. If this field is empty, no specific group ID has been assigned. In that case, the started task runs under the default group of the selected user ID.

ORDER, ORG

The original order (entry number) of this started procedure in the started procedure table. The first entry in the table has ORDER=1.

PRIVILEGED

Flag field that indicates in a RACF system that the started procedure runs with the privileged attribute. All access requests–except those that request a profile to be returned in-storage through the use of the CSA or PRIVATE keywords–are granted and auditing is suppressed. If the PRIVILEGED flag is set, RACF ignores the value of the TRUSTED setting. Accordingly, the SPT NEWLIST, also reports that the TRUSTED flag as not set.

PROCNAME

The name of the started procedure. When combined with the SYSTEM field, this field identifies an entry in this NEWLIST type.

The last entry in the table can contain an asterisk (*) to indicate a generic entry. Actual procedures matching this entry can be displayed by running VERIFY STC.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system ID. The field length is 8 characters to cater to VM systems. When combined with the PROCNAME field, this field identifies an entry in this NEWLIST.

TRUSTED

Flag field that indicates that the started procedure in a RACF system runs with the trusted attribute. Most access request are granted and only limited auditing possibilities exist. Access requests that request a profile to be returned in-storage through the use of the CSA or PRIVATE keywords are not authorized. Auditing is only possible using SETROPTS LOGOPTIONS and the UAUDIT setting for the user ID. If the PRIVILEGED flag is set, RACF ignores the value of the TRUSTED setting. Accordingly, SPT NEWLIST TYPE, also reports the TRUSTED flag as not set.

USER, USERID

The RACF user ID assigned to this started procedure. If this field is empty, no specific user ID has been assigned, which means that the started procedure runs under the generic entry, PROCNAME=*.

SUBSYS: MVS Subsystems

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The SUBSYS NEWLIST (NEWLIST TYPE=SUBSYS) describes the MVS subsystems. Each entry can be uniquely identified by either SYSTEM NAME or SYSTEM ORG.

Field descriptions

The SUBSYS NEWLIST provides the following fields for reporting.

ARDR

Flag field that describes the ARDR flag, which indicates if the subsystem supports the allocation of a special internal reader.

AUDITCONCERN

Indicates the reason for the audit priority. Do not rely on the exact value of this field in your programs because the contents can change. This field can contain any of the following audit concerns.

- **Control block in user-key common storage**

  Either the SSCT or the SSVT lies in writable common storage making it possible for any user to change the subsystem. If the SSCT is writable, immediate action is required. If the SSVT is writable, the subsystem must be reviewed to see whether the SSVT is actually used.

- **Function in user-key common storage**

  A subsystem function lies in writable common storage making it possible for any user to change the function code to subvert the subsystem. If the subsystem function runs authorized, the change can potentially subvert the whole MVS system. Immediate action is required.

- **User pointer in user-key common storage**

  The SUSE or SUS2 user pointer seems to point to writable common storage. The subsystem must be reviewed. First, check whether the SUSE and SUS2 pointers are actually used. If random user data is used, then this is a false alarm. Second, check the use of the writable data. If the subsystem does not use the areas, no immediate action is required. However, the supplier of the subsystem should not use user-writable common storage. If the subsystem uses the area as a vector table, this audit concern is serious.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 544. SUBSYS NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. This value can be taken from the `ALLOC COMPLEX` parameter or default to a system name.

DESCRIPTION

Text field that contains a description of the subsystem, if it is known to zSecure. The value is the name of the package that normally creates this subsystem. Do not rely on the exact value of this field in your programs because the contents can change.

FIB

Flag field that indicates whether serialization of Foreground Initiated Background (FIB) requests is required. For example, TSO provides the FIB commands SUBMIT, CANCEL, and STATUS.

FUNCTION

This repeated field contains the documented description of a subsystem function. It is part of the structured repeat group described with FUNCTION_NO.

Note: The FUNCTION field is only available if the SSVT_ADDRESS field is not zero.

FUNCTION_ADDRESS

This repeated field contains the address of a subsystem function. It is part of the structured repeat group described with FUNCTION_NO.

Note: Only available if the SSVT_ADDRESS field is not zero.

FUNCTION_AMODE

This repeated field contains the addressing mode of a subsystem function. It is part of the structured repeat group described with FUNCTION_NO. The value can be *24* or *31*.

FUNCTION_AT

This repeated field contains a short description of the program name, module name, and offset, in the format described in Table 545. The field is part of the structured repeat group described with FUNCTION_NO.

Table 545. FUNCTION_AT field formats

FUNCTION_AT format	Minor/Major EP	Offset zero
Module	Major	Yes
Module+offset	Major	No
Program in Module	Minor	Yes
Program+offset in Module	Minor	No

Note: The FUNCTION_AT value is only available if the SSVT_ADDRESS field is not zero.

FUNCTION_CONTENT

This repeated field contains up to the first 256 bytes of a subsystem function, which usually includes the eye catcher. The default output length of this string is 128 characters, containing the first 128 bytes of the function. In the default output format, the readable text from the contents is shown. The non-printable parts of the contents have been replaced by one or two dots. This field is part of the structured repeat group described by the FUNCTION_NO field.

Note: The FUNCTION_CONTENT value is only available if the SSVT_ADDRESS field is not zero.

FUNCTION_KEY

This repeated field contains the storage protection key of a subsystem function, if the residency is in CSA, ECSA, SQA, or ESQA.

A key of 8 is a serious cause for concern because any user can change the subsystem function. A key in the range 9-15 is a minor cause for concern. Only

users running in that key are able to change the subsystem function. Normally, keys 9-15 are used only by controlled applications when running programs from APF libraries. An exception applies to ADDRSPC=REAL. See 1451. This field is part of the structured repeat group described with FUNCTION_NO.

Note: The FUNCTION_KEY value is only available if the SSVT_ADDRESS field is not zero.

FUNCTION_LENGTH

If residency is in the LPA (EFLPA, EMLPA, EPLPA, FLPA, MLPA, PLPA), this repeated field contains the length of the program or module that the function is part of. The field length is approximated as either the length up to the end of the module or the length up to the next entry point. This field is part of the structured repeat group described by the FUNCTION_NO.

Note: The FUNCTION_LENGTH value is only available if the SSVT_ADDRESS field is not zero.

FUNCTION_MODULE

If residency is in the LPA (EFLPA, EMLPA, EPLPA, FLPA, MLPA, PLPA), this repeated field contains the major entry point name of the module in which a subsystem function is located. This field is part of the structured repeat group described by the FUNCTION_NO field.

Note: The FUNCTION_MODULE value is only available if the SSVT_ADDRESS field is not zero.

FUNCTION_NO

This repeated field contains the number (index) of a subsystem function. It is a unique key in the FUNCTION structured repeat group, which consists of the following fields:

FUNCTION_NO, FUNCTION_ADDRESS, FUNCTION
FUNCTION_AT, FUNCTION_AMODE, FUNCTION_CONTENT
FUNCTION_KEY, FUNCTION_SUBPOOL, FUNCTION_MODULE
FUNCTION_PROGRAM, FUNCTION_LENGTH, FUNCTION_OFFSET
FUNCTION_SCANINS, FUNCTION_SCANSTR, FUNCTION_WHERE

Note: The FUNCTION_NO value is only available if the SSVT_ADDRESS field is not zero.

FUNCTION_OFFSET

If the residency is in the LPA (EFLPA, EMLPA, EPLPA, FLPA, MLPA, PLPA), this repeated field contains the offset from the entry point for the program and the function address, The offset is calculated from the previous entry point. The value is zero if the address is located in a minor or major entry point. This field is part of the structured repeat group described by the FUNCTION_NO field.

Note: The FUNCTION_NO value is only available if the SSVT_ADDRESS field is not zero.

FUNCTION_PROGRAM

If the residency is in the LPA (EFLPA, EMLPA, EPLPA, FLPA, MLPA, PLPA), this repeated field contains the entry point name of a subsystem function. If the address is at or just following a minor entry point, this value is the minor entry point name. If the address is at or just following a major entry point, this value

is the major entry point name and is equal to the FUNCTION_MODULE field. The FUNCTION_PROGRAM field is part of the structured repeat group described with FUNCTION_NO.

Note: The FUNCTION_NO value is only available if the SSVT_ADDRESS field is not zero.

FUNCTION_SCANINS

This repeated field describes the result of an *instruction scan* performed on the subsystem function code. This field is part of the structured repeat group described by the FUNCTION_NO field. It is only available if the CKFREEZE file used as the data source was produced with the zSecure Collect SCAN=YES parameter. The instruction scan is performed on the full length of the subsystem function, not just on the eye catcher. The scan checks for suspicious instructions in the code.

Note: Interpret the contents of this field as a warning, not as a certainty. The instruction scan can cause false alarms, and can also be fooled to miss certain instructions. Always review the source code of suspicious modules.

Note: The FUNCTION_SCANINS field is only available if the SSVT_ADDRESS field is not zero.

When used for SELECT and EXCLUDE processing, you can use SELECT FUNCTION_SCANINS or SELECT FUNCTION_SCANINS=ANY to select routines in which *any* specified instruction was found. Use SELECT FUNCTION_SCANINS=NONE to select routines in which no specified instructions were found. In addition, you can select routines containing any of the specific instructions listed in the following table, SELECT FUNCTION_SCANINS=(FAKEAPF,FAKESPEC) for example.

Because many suspicious instructions can be found within a single module, the output of this field is in a condensed format. Table 546 lists the FUNCTION_SCANINS values that can be used for SELECT and EXCLUDE processing, the condensed output, and the meaning.

Table 546. FUNCTION_SCANINS field - values and format

SELECT/EXCLUDE	Condensed	Meaning
BYPASS BYPASSSAF	.B.....	Request DFP (DFSMS) to bypass SAF calls
FAKEAPF	A.....	Fake APF/AC(1)-authorization
FAKEOPER	.....O.	Set RACF operations authority
FAKEPRIV	......P	Set RACF privileged/trusted authority
FAKESPEC	....S..	Set RACF special authority
KEYZERORB	...0...	For an SVC: modify caller's RB to key-zero
MODESUPRB	..M....	For an SVC: modify caller's RB to supervisor mode

Note: The values printed by the FUNCTION_SCANINS field are subject to change. Do not rely on the exact value of this field in your programs because the content can change.

FUNCTION_SCANSTR

This repeated field describes the result of a *string scan* performed on the subsystem function code. This field is part of the structured repeat group described with FUNCTION_NO. It is only available if the CKFREEZE file used was produced with the SCAN=YES parameter and SCANSTR arguments set. The string scan is performed on the full length of the subsystem function (not just on the eye catcher), and checks for user-specified strings in the code.

The field can have any of the following values: *Yes* if a matching string was encountered in the code. *No* if no such string was found, blank if no string scan was performed.

Note: The FUNCTION_SCANSTR value is only available if the SSVT_ADDRESS field is not zero.

FUNCTION_SUBPOOL

This repeated field contains the storage area subpool of a subsystem function if the residency is in CSA, ECSA, SQA, or ESQA. It is part of the structured repeat group described with FUNCTION_NO.

Note: The FUNCTION_SUBPOOL value is only available if the SSVT_ADDRESS field is not zero.

FUNCTION_WHERE

This repeated field contains the residency of a subsystem function. See the SSCT_WHERE field for a reference. This field is part of the structured repeat group described with FUNCTION_NO.

Note: The FUNCTION_WHERE value is only available if the SSVT_ADDRESS field is not zero.

MAX_FUNCTIONS

This field describes the maximum number of function addresses (as opposed to function indices) defined for the subsystem. See the structured repeat group described with the FUNCTION_NO field.

Note: The MAX_FUNCTIONS value is only available if the SSVT_ADDRESS field is not zero.

NAME

The subsystem name. The subsystem name is unique within each system.

ORG, ORDER

The original order in the list of subsystems; this is unique within each system. The *primary* subsystem (usually JES2 or JES3) has ORG value 1.

PSS

This flag field describes the Primary Subsystem Services (PSS) flag, which indicates whether the primary subsystem's services are used when starting this subsystem. If this flag is set (PSS=YES), a START command where the procedure name equals the subsystem name is automatically started under the primary JES. If the flag is not set, the task is automatically started as if SUB=MSTR was specified on the START command.

SSCT_ADDRESS

The address of the subsystem table (SSCT). See also the SSCT_KEY, SSCT_SUBPOOL, and SSCT_WHERE fields.

SSCT_KEY

The storage protection key of the subsystem table, if the table is in CSA, ECSA, SQA, or ESQA. See also the SSCT_ADDRESS, SSCT_SUBPOOL, and SSCT_WHERE fields.

A key of 8 is a serious cause for concern because any user can change the subsystem table. A key of 9-15 is a minor cause for concern. Only users running in that key can change the subsystem table. Normally, keys 9-15 are used only by controlled applications when running programs from APF libraries. An exception applies to ADDRSPC=REAL, see 1451.

SSCT_SUBPOOL

The storage area subpool of the subsystem table if the table is in CSA, ECSA, SQA, or ESQA. See also the SSCT_ADDRESS, SSCT_KEY, and SSCT_WHERE fields.

SSCT_WHERE

The residency of the subsystem table. See also the SSCT_ADDRESS, SSCT_KEY, and SSCT_SUBPOOL fields. Possible SSCT_WHERE values and their meaning are documented in the following table; areas starting with an E reside above the 16 MB line virtual storage. [21]

SSCT_WHERE value	Meaning
CSA	Common Storage Area
ECSA	Extended Common Storage Area
EFLPA	Extended Fixed Link Pack Area
EMLPA	Extended Modified Link Pack Area
ENUC RO	Read-only Extended Nucleus Area
ENUC RW	Writable Extended Nucleus Area
EPLPA	Extended Pageable Link Pack Area
EPVT	Extended Private Area
ESQA	Extended System Queue Area
FLPA	Fixed Link Pack Area
MLPA	Modified Link Pack Area
NUC RO	Read-only Nucleus Area
NUC RW	Writable Nucleus Area
PLPA	Pageable Link Pack Area
PSA	Prefix Storage Area
PVT	Private Area
SQA	System Queue Area

SSVT_ADDRESS

The address of the subsystem's Communication Vector Table (SSVT). See also the SSVT_KEY, SSVT_SUBPOOL, and SSVT_WHERE fields. If zero, the subsystem does not have a communication table; the SSVT_KEY, SSVT_SUBPOOL, and SSVT_WHERE fields, as well as the FUNCTION structured repeat group, are not available.

21. The full Virtual Storage Map is described in the NEWLIST TYPE=VSM.

SSVT_KEY

The storage protection key of the Communication Vector Table (SSVT) for the subsystem if the table is in CSA, ECSA, SQA, or ESQA. See also the SSVT_ADDRESS, SSVT_SUBPOOL, and SSVT_WHERE fields.

A key of 8 is a serious cause for concern because any user can change the SSVT. A key in the range 9-15 is a minor cause for concern. Only users running in that key can change the SSVT. Normally, keys 9-15 are only used by controlled applications when running programs from APF libraries. An exception applies to ADDRSPC=REAL. See 1451.

Note: The SSVT_KEY value is only available if the SSVT_ADDRESS field is not zero.

SSVT_SUBPOOL

Contains the storage area subpool of the Communication Vector Table (SSVT) for the subsystem if the table is in CSA, ECSA, SQA, or ESQA. See also the SSVT_ADDRESS, SSVT_KEY, and SSVT_WHERE fields.

Note: The SSVT_SUBPOOL value is only available if the SSVT_ADDRESS field is not zero.

SSVT_WHERE

The residency of the Communication Vector Table (SSVT) for the subsystem. See also the SSVT_ADDRESS, SSVT_KEY, SSVT_SUBPOOL, and SSVT_KEY fields.

Note: The SSVT_WHERE value is only available if the SSVT_ADDRESS field is not zero.

SUS2_ADDRESS

The SUS2 address. The SUS2 value is treated as a pointer; the derived SUS2 values are invalid if the subsystem uses the SUS2 value for other purposes.

SUS2_CONTENTS

The SUS2 contents. The first 8 characters of the area pointed to by the SUS2 pointer, with non-printable characters replaced by a period.

SUS2_KEY

The storage protection key of the SUS2 pointer if it is in CSA, ECSA, SQA, or ESQA.

A key of 8 is a serious cause for concern because any user can change the SUS2. A key in the 9-15 range is a minor cause for concern. Only users running in that key can change the SUS2. Normally, keys 9-15 are used only by controlled applications when running programs from APF libraries. An exception applies to ADDRSPC=REAL, see 1451.

Note: The SUS2_KEY value is only available if the SUSE_ADDRESS field is not zero.

SUS2_SUBPOOL

The storage area subpool of the SUS2 pointer if it is in CSA, ECSA, SQA, or ESQA.

Note: The SUS2_SUBPOOL value is only available if the SUSE_ADDRESS field is not zero.

SUS2_WHERE

The SUS2 residency. See the SSCT_WHERE field for a reference.

Note: The SUS2_WHERE value is only available if the SUSE_ADDRESS field is not zero.

SUSE_ADDRESS

The SUSE address. The SUSE value is treated as a pointer. The derived SUSE values are invalid if the subsystem uses the SUSE value for other purposes.

SUSE_CONTENTS

The SUSE contents. The first 8 characters of the area pointed to by the SUSE pointer, with non-printable characters replaced by a period.

SUSE_KEY

The storage protection key of the SUSE pointer if it is in CSA, ECSA, SQA, or ESQA.

A key of 8 is a serious cause for concern because any user can change the SUSE pointer. A key between 9-15 is a minor cause for concern. Only users running in a key within that range can change the SUSE pointer. Normally, keys 9-15 are used only by controlled applications when running programs from APF libraries. An exception applies to ADDRSPC=REAL. See 1451.

Note: The SUSE_KEY value is only available if the SUSE_ADDRESS field is not zero.

SUSE_SUBPOOL

The storage area subpool of the SUSE pointer if it is in the CSA, ECSA, SQA, or ESQA.

Note: The SUSE_SUBPOOL value is only available if the SUSE_ADDRESS field is not zero.

SUSE_WHERE

The SUSE residency. See the SSCT_WHERE field for a reference.

Note: The SUSE_WHERE value is only available if the SUSE_ADDRESS field is not zero.

SYSTEM

The name of the system. For MVS systems, the value equals the SMF system ID. The field length is 8 characters for compatibility with other NEWLIST types.

When combined with the ORG or the NAME field, the SYSTEM field uniquely identifies an entry in this NEWLIST type.

TYPE

A string indicating the subsystem type. The value is either JES2 or JES3, or blank.

SVC: Supervisor Calls

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

The SVC NEWLIST (NEWLIST TYPE=SVC) describes the MVS SVCs and ESRs, their attributes, and information on previous versions of the SVC read from the SVC

update table. Each entry in this NEWLIST can be uniquely identified by the fields SYSTEM SVCNO ESRNO. If a single system is analyzed, SVCNO ESRNO is a unique key.

Up to five versions of each SVC and derived fields can be found: The current SVC, the old and new versions of the SVC logged in the SVC update table, the SVC as described in the zSecure knowledge base, and routines matching the default name of the SVC (the IPL version). In most cases, some of these versions do not exist, or are equal to another version. Because of this, the SVC NEWLIST groups SVC version-dependent fields into a repeat group, with a single repeat group for each version. An INDEX field indicates which versions are grouped together in a single repeat group entry.

For example, if all versions of an SVC are the same, there is a single repeat group entry. The INDEX field indicates the versions found. If the SVC was updated once using SVCUPDTE, two repeat group entries are listed, one for the current entry and the *new* entry registered in the SVC update table and one matching the *old* entry, the knowledge base, and the IPL version.

The fields included in the SVC NEWLIST fit into one of the following categories:

- Fields describing the overall SVC, which include information like the SVC number or the result of an analysis.
- Fields describing a version of the overall SVC which are repeated once for each different version and described by the INDEX field.
- Fields describing the current SVC. These fields have names starting with CURR_; most are available for every entry (except for some derived fields).
- Fields describing the default or expected SVC, as defined in the zSecure knowledge base and the ***Diagnosis Reference***. These fields have names starting with EXP_, and are available for all default SVCs.
- Fields describing the attributes of the previous SVC, as recorded in the SVC update table. These fields have names starting with OLD_ and are available only if an entry in the SVC update table is available.
- Fields describing the update table, the update date for the table for example. These fields have names starting with UPDATE_ and are available only if an entry in the SVC update table is available.
- Fields describing the caller of the SVCUPDTE service. These fields these have names starting with CALLER_, and are available only if an entry in the SVC update table is available.

Field descriptions

The SVC NEWLIST provides the following fields for reporting.

ADDRESS

This repeated field is part of the structured repeat group described with the INDEX field; it describes the address of the current repeat-group entry. This field is an 8-long (4-byte) hexadecimal number.

AMODE

This repeated field is part of the structured repeat group described with the INDEX field; it describes the addressing mode of the current repeat group entry. This field can have any of the following values: *24*, *31*, *64*.

APPL

The application name of the SVC taken from the internal knowledge base.

AT

This repeated field is part of the structured repeat group described with the INDEX field. The value contains a short description of the program name, module name, and offset, in the format described in Table 547.

Table 547. AT field values

AT format	Minor/Major EP	Offset zero
Module	Major	Yes
Module+offset	Major	No
Program in Module	Minor	Yes
Program+offset in Module	Minor	No

AUDITCONCERN, CONCERN

Indicates the reason for the audit priority. Do not rely on the exact value of this field in your programs as the contents might change. The AUDITCONCERN field can contain one or more concerns separated by commas. Table 548 describes the audit concerns that are currently defined.

Table 548. SVC: Audit concerns and descriptions

Audit Concern	Meaning
APF mismatch	The SVC requires APF authorization according to operating system documentation for this release, but the SVC configuration does not include it. This condition indicates a serious security exposure that can be the result of a hacker creating an unobtrusive back door into the system.
Caller may be unauthorized	Any program can call the SVC. This configuration is true for most SVCs. By itself, it is not a cause for concern, unless the SVC performs sensitive actions. In that case, the SVC must check the authorization of the caller itself. If an installation-defined SVC is configured only for use by authorized programs, it must not be callable by unauthorized programs. Hacking attempts usually focus on this type of SVC.
Code size suspect	The size of the SVC is less than 256 bytes. The small size might indicate inadequate security checks implemented for an SVC that can be called by arbitrary (non-APF) users. A code review is warranted. 90% of a safe SVC is typically spent in user and parameter authorization checking. If the size of the SVC is less than 32 bytes, a *Dangerous code size* concern is issued.
Dangerous code size	The size of the SVC is less than 32 bytes. It is possible that the SVC does not have proper user and parameter authorization checks for the arbitrary (non-APF) caller. A code review is warranted. See also concern *Code size suspect* that is issued if the code size is somewhat larger.
ESR mismatch	The SVC is used as an ESR or an ESR is used as an SVC. This serious concern must be corrected because installation-defined *new* ESRs must not exist, and no system-defined ESR can be redefined as an SVC.
IBM-range SVCno	An SVC has been updated in the range of IBM-defined SVCs, which can be used by all programs or OS services. This concern implies that an IBM-defined SVC has been updated or front-ended. Review the SVC to ensure that the IBM-defined function is still performed and properly protected.

Table 548. SVC: Audit concerns and descriptions (continued)

Audit Concern	Meaning
In application common storage	The actual SVC code has storage key 10, 11, 12, 13, 14 or 15. An application that runs in any of those keys might change it, irrespective of who calls the application. This condition is not as serious as having a storage key of 8 or 9, but it is not as safe as having key 0 storage. Review the application code.
In (E)CSA/(E)SQA	The SVC routine has been added dynamically to the system in non-page protected storage. Typically, this conditions suggests that the routine is part of a third-party product and as such worthy of vulnerability analysis. Also, the routine might not be part of SMP/E or not recognizable as SVC code in SMP/E. As a result, it might have escaped change management procedures normally followed for SVCs. By itself, this condition is not a serious concern.
In (E)FLPA	This indicates code that resides in the Fixed Link Pack Area. The same concerns apply as for MLPA; the difference is that the real storage pages are persistent.
In (E)MLPA	Indicates that the code resides in the Modified Link Pack Area. The software does not reside in the LPA libraries, but has been expressly loaded into MLPA. The most common reasons for this condition are: 1) The code is a test version overruling the PLPA version. 2) The code is not fully reenterable or refreshable or requires modifiable storage because it stores state information. In the first case, you are not running the software configuration (versions) reflected in the SMP/E CSI. In both cases, if the MLPA is not page protected, the software is more vulnerable than in the LPA
In (E)PVT	The SVC was defined in private storage. It can only be used by the owning address space. All other users can run the code occupying the assigned memory area. Invocation of the SVC can result in unpredictable processing, storage overlays, system abends, or hackers taking over the system.
In writable common storage	The SVC is located in a memory area that can be modified by all general users of the system. As a result, the actual code run as part of the SVC processing can be unpredictable, possibly resulting in-storage overlays, system abends, or hackers taking over the system. Immediate action is required.
Installation-defined SVCno	The SVC has no IBM-standard SVC number, and hence is not likely to have been checked by IBM for integrity exposures. On the other hand, if you really need your own SVC, the range of installation-defined SVC numbers is the proper place to define them.
Instruction scan hit (as expected)	The SVC routine contains an instruction that might be used to circumvent normal system security. For example, an instruction that sets a permanently authorized bit from temporarily authorized code, or an instruction that fakes authorization for an unauthorized caller. These things are an exposure if they are not reset before leaving the SVC. Another possible hit is issuing authorized RACF functions that would not be allowed outside the SVC code. All these instruction scan hits warrant a further vulnerability analysis of the SVC code. This concern might be followed by *as expected* when the SVC is known to the program, and known to contain these instructions.

Table 548. SVC: Audit concerns and descriptions (continued)

Audit Concern	Meaning
Known small code size	The size of the SVC is less than 256 bytes. The SVC is known to the program, and known to be this size, so the priority of the SVC is lower than the priorities for other code size concerns like the *Dangerous code size* and *Code size suspect* concerns.
Lock mismatch	The SVC was updated using SVCUPDTE, and the locks required for the current SVC do not match the locks required for the old SVC. If the new SVC front-ends the old SVC, it must acquire or release the locks for the old SVC to function correctly. Review the new SVC to make sure this is the case.
Reserved SVCno	An SVC has been defined in the IBM-reserved range of SVC numbers. This number range must only be used by IBM-defined product-dependent SVCs. Although many third-party vendors use these numbers, their use can lead to conflicts with IBM products.
Same as another SVC	The SVC routine is called by more than one SVC number. This condition is suspicious unless it is the error SVC. It is especially suspicious if one copy requires APF authorization and the other does not.
String scan hit	The SVC routine contains a string specified or implied in the zSecure Collect run. The default string for such a run is an instruction sequence that is unsafe when the routine has the `AC(1)` attribute instead of the correct `AC(0)` attribute.
Suspected frontending	The SVC routine is not installation defined, but nonetheless stored in (E)CSA or (E)SQA. IBM supplied SVCs are never stored in (E)CSA, so this warrants a careful examination.
Suspect SVC inst	The SVC starts with another SVC instruction. Being part of another SVC, the called SVC can bypass normal authorization verifications. Resulting processing can cause a circumvention of normal system integrity controls exploitable by hackers.
SVC scan hit (as expected)	This SVC calls another SVC that is dangerous. Analyze the SVC code to verify that it does not simply pass a user-specified parameter list but only authorizes very specific functions that cannot be misused. The exact list of SVCs scanned for is set by the zSecure Collect parameter `SCANSVC`. The default for that parameter is the SVC codes for the resident security system (RACF or ACF2). This concern can be followed by *as expected* when the SVC is known to the program and known to call these SVCs. In that case, the audit priority is lower.
Type mismatch	The SVC should be defined as a different type than it was actually found in the system (Based on the operating system documentation for the specific release, the SVC type is not defined correctly. This condition might result in incorrect processing, but usually this condition is caused by a documentation error or backlog.
Unsafe branch	The SVC uses a register whose contents are caller-specified as index or base for a branch instruction. The branch location is therefore not predictable by the SVC code. Running the SVC can result in unpredictable processing, storage overlays, system abends, or hackers taking over the system.

Table 548. SVC: Audit concerns and descriptions (continued)

Audit Concern	Meaning
Unsafe STM	The SVC stores several registers at the location pointed to by Register 13. This condition is common coding practice for normal user programs. For SVCs, the contents of register 13 is caller-specified. The SVC might cause storage overlays resulting in unpredictable behavior, system abends, or hackers taking over the system.
Updated during NIP	The SVC table has been changed, but the change occurred during Nucleus Initialization Processing, probably as part of regular link pack area creation. This change does not contribute to the audit priority and indicates that the change is nothing to worry about.
Updated twice in RACF startup	The SVC table has been changed twice, but these changes are normal for RACF startup processing of RACF SVCs. This change does not contribute to the audit priority and indicates that the SVCUPDTE change is nothing to worry about.
Updated using SVCUPDTE	The SVC was updated using the SVCUPDTE service. This SVC routine is not the original code as installed under the module name used for this SVC number by default. The routine has been changed dynamically through the documented dynamic SVC update procedure SVCUPDTE. If this concern is issued in connection with an IBM SVC, the installed code is usually a frontend to the regular SVC.
Updated without SVCUPDTE	SVC routine is not the original code as installed under the module name used for this SVC number by default, but has been changed dynamically. The change has not been done through the documented dynamic SVC update procedure, pointing to possibly dangerous coding practices by the software vendor. If this concerns an IBM SVC, the installed code is usually a 'front-end' to the regular SVC. The new SVC must be reviewed.

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 549. SVC NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

CALLER_ADDRESS

The address of the last caller of the SVCUPDTE service, as a 4 byte hexadecimal number. This field is only available if an entry in the update table is available for the current SVC.

From the caller address, the CALLER_AT and CALLER_WHERE fields are derived.

CALLER_AT

The entry point location at the caller address. This field is available only if an entry in the update table is available for the current SVC. See also the CALLER_ADDRESS and CALLER_WHERE fields; see the AT field for a reference.

CALLER_WHERE

The residency of the memory area at the caller address. This field is only available if an entry in the update table is available for the current SVC. See also the CALLER_ADDRESS and CALLER_AT fields. See the WHERE field for a reference.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. This value can be taken from the ALLOC COMPLEX parameter or default to a system name.

CONTENTS

This repeated field is part of the structured repeat group described with the INDEX field; it describes the contents of the current repeat group entry. This field is a string containing up to the first 256 bytes of the SVC, which usually include the eye catcher. In the default output format, the readable text from the contents is shown. The non-printable parts of the contents have been replaced by one or two periods (. or ..) .

CURR_ADDRESS

The entry point of the current SVC, as a 4 byte (8 positions) hexadecimal number. See also the ADDRESS field.

CURR_AMODE

The addressing mode of the current SVC. This field can have the following values: *24* or *31*.

CURR_APF

Flag indicating whether the current SVC requires the caller to be APF-authorized.

CURR_AT

This field contains a short description of the program name for the current SVC, module name, and offset in the format described by the AT field.

CURR_ATTR

The SVC attributes (other than APF, ESR, and LOCKS). This is a three-position character field with the following values:

ATTR value	Meaning
A	SVC can be run in Access Register mode
N	SVC cannot be preempted
S	SVC can be assisted by hardware

CURR_CONTENTS

A string containing up to the first 256 bytes of the current SVC code, which usually include the eye catcher. The default output length of this string is 128 characters (containing the first 128 bytes of the SVC code). In the default output format, the readable text from the contents is shown. The non-printable parts of the contents have been replaced by one or two periods (. or ..). See also the CONTENTS field.

CURR_ESR

Flag indicating whether the current SVC is an ESR entry.

Note: An SVC table entry that points to an ESR table is not included as an entry.

CURR_KEY

The storage protection key of the memory area at the entry point for the current SVC. That is, at the CURR_ADDRESS. See also the KEY field.

CURR_LENGTH

The length of the current SVC program; see also the LENGTH field.

CURR_LOCK

This field describes the system locks required by the SVC. It contains a character for each lock type required, and a blank for each lock type not required. This field has the format CDLOS; the meaning of these characters is described in Table 550.

Table 550. CURR_LOCK values

Character	SVC lock types
C	CMS
D	DISP
L	LOCAL
O	OPT
S	SALLOC

CURR_MODULE

This field contains the major entry point name for the current SVC.

CURR_OFFSET

This field contains the offset between the entry point for the current SVC and the next prior entry point. See the OFFSET field.

CURR_PROGRAM

This field contains the major entry point/minor entry point name for the current SVC. See the PROGRAM field.

CURR_RESULT

This field contains the result of the SVC disassembly. Currently, only the 'do-nothing' program IEFBR14, the error SVC, and the error ESR are recognized. See the RESULT field.

CURR_SAME_AS

This field contains the first SVC or ESR that has the same entry point as the current SVC. It has the format 'SVC 100' or 'ESR 109/24'. See the SAME_AS field.

CURR_SCAN_INSTR

This field describes the result of an *instruction scan* performed on the code for the current SVC. It is only available if the CKFREEZE file used was produced with the SCAN=YES parameter. The instruction scan is performed on the full length of the SVC (not just on the eye catcher), and checks for suspicious instructions in the code.

Note: Interpret the contents of this field as a warning, not a certainty. The SVC scan can cause false alarms and can also be fooled to miss certain SVC calls. Always review the source code of suspicious modules.

When used for SELECT and EXCLUDE processing, you can use SELECT CURR_SCAN_INSTR or SELECT CURR_SCAN_INSTR=ANY to select routines in which *any* instruction was found; use SELECT CURR_SCAN_INSTR=NONE to select routines in which no instructions were found. In addition, you can select routines containing any of the specific instructions listed in Table 551, SELECT CURR_SCAN_INSTR=(FAKEAPF,FAKESPEC) for example.

Because many suspicious instructions can be found within a single module, the default output of this field is in a condensed format. Full output split into several lines can be requested using the EXPLODE output modifier and an overriding length of 9, CURR_SCAN_INSTR(EXPLODE,9 for example. Table 551 lists the CURR_SCAN_INSTR values that can be used for SELECT/EXCLUDE processing; the condensed output; the exploded output; and the meaning.

Table 551. CURR_SCAN_INSTR values

Select/Exclude	Condensed	Exploded	Meaning
BYPASS BYPASSSAF	.B.....	BypassSAF	Request DFP (DFSMS) to bypass SAF calls
FAKEAPF	A.....	FakeAPF	Fake APF/AC(1)-authorization
FAKEOPER	.....O.	FakeOper	Set RACF operations authority
FAKEPRIV	......P	FakePriv	Set RACF privileged/trusted authority
FAKESPEC	....S..	FakeSpec	Set RACF special authority
KEYZERORB	...0...	KeyzeroRB	For an SVC: change the RB for the caller to key-zero
MODESUPRB	..M....	ModeSupRB	For an SVC: change the RB for the caller to supervisor mode

Note: The values printed by the CURR_SCAN_INSTR field are subject to changes in future releases. Do not write applications that are dependent on the output of this field.

CURR_SCAN_STRING

This field describes the result of a *string scan* performed on the SVC code. It is only available if the CKFREEZE file used was produced with the SCAN=YES

parameter and SCANSTR arguments set. The string scan is performed on the full length of the SVC (not just on the eye catcher), and checks for user-specified strings in the code.

The value of this field is set to *Yes* if a matching string was encountered in the code; *No* if no such string was found; the field is left blank if no string scan was performed.

CURR_SCAN_SVC

This repeated field describes the result of an SVC scan performed on the SVC code. It is only available if the CKFREEZE file used was produced with the SCAN=YES parameter and SCANSVC list of SVC numbers set. The SVC scan is performed on the full length of the SVC not just on the eye catcher and also checks for user-specified SVC calls in the code.

Note: Interpret the contents of this field as a warning, not a certainty. The SVC scan can cause false alarms and can also be fooled to miss certain SVC calls. Always review the source code of suspicious modules.

The value of this field has the format `num: description` if the SVC scanned for was one of the first seven specified in zSecure Collect. If any of the other SVCs scanned for was encountered, this field has the value *Other*.

CURR_SUBPOOL

This field contains the storage area subpool of the current SVC, if the residency is in CSA, ECSA, SQA, or ESQA. See the SUBPOOL field.

CURR_TYPE

The type of the current SVC. This field is 3 characters long and can have any of the following values: *1*, *2*, *3/4*, or *6*. The SVC type determines the module naming convention.

CURR_WHERE

String field that indicates the virtual storage area where the current `SVC` resides. See the `WHERE` field.

ESRNO

This field is undefined for a normal SVC. If the current `SVC` is an extended SVC as indicated by the `ESR=YES`, this field contains the `ESRNO` table index. This value is the number passed in R15 when the SVC is called.

EXP_APF

Flag field that indicates if the expected SVC (from the database) with the current `SVCNO` and `ESRNO` requires the caller to be APF-authorized.

EXP_ESR

Flag field that indicates if the expected `SVC` (from the database) with the current `SVCNO` is an ESR entry.

EXP_PROGRAM

The program name of the expected SVC (from the database) with the current `SVCNO` and `ESRNO`.

EXP_TYPE

The type of the expected SVC (from the database) with the current `SVCNO`. This field is 3 characters long and can have any of the following values: *1*, *2*, *3/4*, or *6*.

FUNCTION

A string of up to 80 characters describing the function of the SVC. If this function is not directly defined, a guess is made based on the value of the PROGRAM field. This guess is printed enclosed in brackets.

INDEX

This repeated field is the anchor for a large group of repeated fields that describe one or more versions of the SVC. It indicates which versions of the SVC are described in these repeated fields. The INDEX field value can be a maximum of 4 characters, each indicating one version. The letters are arranged in reverse chronological order. That is, the most recent version first.

Index	Meaning
C...	The current SVC, for example, the version that is used if an SVC call is issued.
.N..	The new SVC as registered in the SVC update table. This value can only occur if the SVC was updated at least once using SVCUPDTE. The *new* version is always equal to the current version, unless the SVC was updated again without using SVCUPDTE.
..O.	The previous *old* SVC as registered in the SVC update table. This index value can only be returned if the SVC was updated at least once using SVCUPDTE. The *old* version is often equal to the IPL version if the SVC was updated once.
...I	The IPL version of the SVC. That is, the in-storage module matching the name that the SVC had before any updates were performed.

INDEXCOUNT

This field describes the number of entries in the structured repeat group described with the INDEX field.

KEY

This repeated field is part of the structured repeat group described with the INDEX field. It describes the storage protection key of the memory area at the entry point, or corresponding address for the SVC if the residency is in CSA, ECSA, SQA, or ESQA.

A key of 8 is a serious cause for concern because any user might be able to change the SVC code. A key of 9 to 15 is a minor cause for concern. Only users running in that key are able to change the SVC code. Keys 9 - 15 can normally be used only by controlled applications when running programs from APF libraries. An exception goes for ADDRSPC=REAL. See 1451.

LENGTH

This repeated field contains the length of the program/module the SVC is part of, if the residency is in the LPA or nucleus. (The length is approximated as the length up to the end of the module, or the length up to the next entry point.) It is part of the structured repeat group described with the INDEX field.

MODULE

If the residency is in the LPA or nucleus, this repeated field contains the major entry point name of the module in which the SVC is located. It is part of the structured repeat group described with the INDEX field.

OFFSET

If the residency is in the LPA or nucleus, this repeated field contains the offset from the entry point for the program and the SVC entry point. The offset is

calculated from the previous entry point. It is zero if the address is located in a minor or major entry point. The OFFSET field is part of the structured repeat group described by the INDEX field.

OLD_APF

Flag field that indicates if the previous SVC (the old entry in the SVC update table) required the caller to be APF-authorized.

OLD_ATTR

The previous SVC (the old entry in the SVC update table) attributes (other than APF, ESR, and LOCKS). See the CURR_ATTR field.

OLD_ESR

Flag field that indicates if the previous SVC was an ESR entry. The previous entry is the old entry in the SVC update table.

OLD_LOCK

Describes the system locks required by the previous SVC. The previous entry is the old entry in the SVC update table. See the CURR_LOCK field for a reference.

OLD_TYPE

The type of the previous SVC. The previous entry is the old entry in the SVC update table. This field is 3 characters long and can have any of the following values: *1*, *2*, *3/4*, or *6*.

PROGRAM

This repeated field contains the entry point name of an SVC if the residency is in the LPA or nucleus. If the address is at or just following a minor entry point, this value is the minor entry point name. If the address is at or just following a major entry point, this value is the major entry point name and is equal to the MODULE field.

The PROGRAM field is part of the structured repeat group described with the INDEX field.

RESULT

This repeated field is part of the structured repeat group described using the INDEX field. It contains the result of the SVC disassembly. Currently, the following values are recognized: The *do-nothing* program IEFBR14– which is the default program in use as ESR 109/36 that just sets RC=4, the error SVC, and the error ESR.

SAME_AS

This repeated field is part of the structured repeat group described with the INDEX field. It contains the first SVC or ESR that has the same entry point as the current entry. It has the format 'SVC 100' or 'ESR 109/24'.

SCAN_INSTR

This repeated field is part of the structured repeat group described with the INDEX field. It describes the result of an *instruction scan* performed on the SVC code. It is only available if the CKFREEZE file used was produced with the SCAN=YES parameter. The instruction scan is performed on the full length of the SVC (not just on the eye catcher), and checks for suspicious instructions in the code.

Note: Interpret the contents of this field as a warning, not a certainty. The SVC scan can cause false alarms and can also be fooled to miss certain SVC calls. Always review the source code of suspicious modules.

When used for SELECT or EXCLUDEprocessing, you can use SELECT SCAN_INSTR or SELECT SCAN_INSTR=ANY to select routines in which *any* specified instruction was found. Use SELECT SCAN_INSTR=NONE to select routines in which no specified instructions are found. In addition, you can select routines containing any of the specific instructions listed in Table 552, SELECT SCAN_INSTR=(FAKEAPF,FAKESPEC) for example.

Because many suspicious instructions can be found within a single module, the output of this field is in a condensed format. Table 552 lists the SCAN_INSTR values that can be used for SELECT and EXCLUDE processing, the condensed output, and the meaning.

Table 552. SCAN_INSTR values for SELECT and EXCLUDE processing

SELECT/EXCLUDE	Condensed	Meaning
BYPASS BYPASSSAF	.B.....	Request DFP (DFSMS) to bypass SAF calls
FAKEAPF	A.....	Fake APF/AC(1)-authorization
FAKEOPER	.....O.	Set RACF operations authority
FAKEPRIV	......P	Set RACF privileged/trusted authority
FAKESPEC	....S..	Set RACF special authority
KEYZERORB	...0...	For an SVC: change the RB for the caller to key-zero
MODESUPRB	..M....	For an SVC: change the RB for the caller to supervisor mode

Note: The values printed by the SCAN_INSTR field are subject to changes in future releases. Do not write applications that are dependent on the output of this field.

SCAN_STRING

This repeated field is part of the structured repeat group described with the INDEX field. It describes the result of a *string scan* performed on the SVC code. It is only available if the CKFREEZE file used was produced with the SCAN=YES parameter and SCANSTR arguments set. The string scan is performed on the full length of the SVC (not just on the eye catcher), and checks for user-specified strings in the code.

The value of this field is set to *Yes* if a matching string was encountered in the code. The value is *No* if no such string was found. The field is left blank if no string scan was performed.

SUBPOOL

This repeated field contains the storage area subpool of an SVC, if the residency is in CSA, ECSA, SQA, or ESQA. It is part of the structured repeat group described with the INDEX field.

SVCNO

The SVC number. For extended SVCs, see the ESRNO field.

SYSTEM

The name of the system. For MVS systems, this value is equal to the SMF system ID. The field length is 8 characters for compatibility with other NEWLIST types.

UPDATE_COUNT

The number of times the SVC has been updated, as registered in the SVC update table.

UPDATE_CURRENT

Flag field that indicates if the SVC update table describes the latest change to the SVC. That is, the time that the SVC was changed using SVCUPDTE, but not changed since. This value is set if both the ADDRESS and the attributes match, if the NEW entry is suppressed in all repeated fields for example.

UPDATE_DATE

The date of the last SVC update registered in the SVC update table. For detailed instructions on how to use this field in SELECT/EXCLUDE specifications, see "Date fields" on page 903.

UPDATE_SUFFIX

This field contains a two-character suffix indicating a parmlib member. It is taken from the SVC update table, and is only set if the SVC was updated through a parmlib IEASVCxx member. In this case, the update suffix contains the last two characters of IEASVCxx **01** for IEASVC01 for example.

WHERE

This repeated field is part of the structured repeat group described with the `INDEX` field. It describes the residency of the current repeat-group entry. Table 553 lists the possible `WHERE` values and their meaning. Areas starting with an `E` reside above the 16 MB line in virtual storage.

Note: The full Virtual Storage Map is described in the `VSM NEWLIST`.

Table 553. WHERE values and descriptions

WHERE value	Meaning
CSA	Common Storage Area
ECSA	Extended Common Storage Area
EFLPA	Extended Fixed Link Pack Area
EMLPA	Extended Modified Link Pack Area
ENUC RO	Read-only Extended Nucleus Area
ENUC RW	Writable Extended Nucleus Area
EPLPA	Extended Pageable Link Pack Area
EPVT	Extended Private Area
ESQA	Extended System Queue Area
FLPA	Fixed Link Pack Area
MLPA	Modified Link Pack Area
NUC RO	Read-only Nucleus Area
NUC RW	Writable Nucleus Area
PLPA	Pageable Link Pack Area

Table 553. WHERE values and descriptions (continued)

WHERE value	Meaning
PSA	Prefix Storage Area
PVT	Private Area
SQA	System Queue Area

SYSTEM: System-wide Options

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

The SYSTEM NEWLIST type provides information about system-wide option settings. System information is reported with one entry per system. Unless otherwise stated, all fields are supported in SELECT and EXCLUDE statements and the following output commands: LIST, SORTLIST, DISPLAY and SUMMARY.

The SYSTEM NEWLIST does not support the AUDITCONCERN keyword because the amount of information to include in display panels and reports is too large. For information on system audit information, see "AUDIT: System setting audit concerns" on page 961.

Field descriptions

The SYSTEM NEWLIST supports the following fields for reporting.

ADSP, SETRADSP, SYSTEMADSP

This RACF flag indicates whether Automatic Data Set Protection (ADSP) is in effect (due to a SETROPTS ADSP command). If set (ADSP=YES), RACF creates a discrete profile for each new data set created by users that have the ADSP attribute on their user profile or on their current connect group. If not set, individual user or connect group ADSP attributes are not honored. This field supports overtype.

AIM_DB_STAGE

Specifies the implementation stage for the Application Identity Mapping feature of RACF. For systems not running RACF this field is missing.

AIM_SMF_RECNO

Contains the SMF record type written by the Proginet SecurPass Audit Information Manager.

APPLAUDIT

Flag field that indicates ifAPPC transactions are audited through the APPL class.

If this keyword is set to *YES*, the start and end of an APPC transaction is audited. This setting only applies when an APPL class is present that has success auditing activated.

If the APPLAUDIT keyword is not specified, APPC start and end events are not audited.

This option setting can also be specified by the SETROPTS APPLAUDIT command.This field supports overtype.

AUDIT_GROUP

Flag field that indicates if RACF is logging all RACF commands and DEFINE requests affecting profiles in the GROUP class. These commands are ADDGROUP, ALTGROUP, CONNECT, DELGROUP, and REMOVE. It reflects the SETROPTS AUDIT(GROUP) setting. This field supports overtype.

AUDIT_USER

Flag field that indicates ifRACF is logging all RACF commands and DEFINE requests affecting profiles in the USER class. These commands are ADDUSER, ALTUSER, CONNECT, DELUSER, PASSWORD, and REMOVE. It reflects the SETROPTS AUDIT(USER) setting. This field supports overtype.

BATCHALLRACF

This RACF flag indicates whether JES is only to accept jobs containing either a valid RACF userid and password or propagated RACF information. If BATCHALLRACF=YES is specified, any job not containing this user identification fails. If this setting is not active, jobs without a RACF user ID run with default authority access based on the permissions defined in the UACC and the Global Access Table.

The option indicated by this flag can be set by a SETROPTS JES(BATCHALLRACF) command. This field supports overtype.

CA1_BATCH

Flag field that indicates if the CA-1 option BATCH is active. It controls access to the TMC Volume and DSNB record(s) in conjunction with the YSVC option, as shown in the CA1_YSVC field. When BATCH is active a second access check is done if the check done for the YSVC option results in conditional access. For rename actions, a third access check is done. These extra checks are done in the DATASET class, with the data set name retrieved from the TMC. For rename operations, a check is also done on the new data set name.

CA1_CREATE

Character string that specifies the access level needed to create a tape. For CA-ACF2 and CA-TopSecret, specify *CREATE* for this setting. For RACF, specify *ALTER*.

CA1_DSE

Flag field that indicates if the CA-1 option DSEALL is active (Data Security Erase). If set, the tape must have been erased by TMSTPPRO with an ERASE parameter before it can be reused.

CA1_DSNB_EFFECTIVE

Flag field that indicates if the CA-1 options `DSNB` and `OCEOV` are both active. If active, then each access to a secondary tape data set results not only in an access check for the data set in question, but also in an access check for the first data set on the tape. This access check is issued as an SAF call for class `DATASET` with the full 44-character data set name of the first file on the first volume of the multi-volume complex. This data set name comes from the CA-1 Tape Management Catalog. The `UNDEF` option, as shown in the `CA1_UNDEF_FAIL` field, regulates what happens when SAF returns RC 4.

CA1_FORNDSN

Contains the value of the CA-1 option FORNDSN. It can be ALL, INPUT, OUTPUT or NONE, indicating for which type of access to nonresident tapes access checks are done in the DATASET class.

CA1_FUNC

Flag field that indicates if the CA-1 option FUNC is active. This option setting causes real-time resource checks for occurrences of the EXPDT=98000 parameter and for use of the following label types: NL, NSL, and BLP.

CA1_OCEOV

Flag field that indicates if the CA-1 option OCEOV is active. If active, then each access to a tape data set results in a SAF call for class DATASET with the full 44-character data set name from the CA-1 Tape Management Catalog. The UNDEF option, as shown in the CA1_UNDEF_FAIL field, regulates what happens when SAF returns RC 4.

CA1_PSWD

Flag field that indicates if the CA-1 option PSWD is active. If active, the user of an online access password must pass a resource check against that password in class CATAPE. The UNDEF option, as shown in the CA1_UNDEF_FAIL field, regulates what happens when SAF returns RC 4.

CA1_UNDEF_FAIL

Flag field that indicates if the CA-1 option UNDEF is set to FAIL. This option regulates whether an "undecided" return code from SAF results in a refusal.

CA1_YSVC

Flag field that indicates if the CA-1 option YSVC is active. If active, then callers of the CA-1 SVC must pass a resource check against YSVCUNCD (for unconditional access) or YSVCCOND (for conditional access) in class CATAPE. When YSVCCOND access is granted, extra checks are performed when the BATCH option is active. When the BATCH option is inactive, conditional access is denied. The UNDEF option, as shown in the CA1_UNDEF_FAIL field, regulates what happens when SAF returns RC 4.

CATDSNS

This string indicates whether RACF prevents users from accessing uncataloged, new or system temporary data sets. It reflects an option set by a SETROPTS CATDSNS command. The following table documents the CATDSNS values, the corresponding SETROPTS commands, and their meanings.

CATDSNS value	SETROPTS command	Meaning
No	SETROPTS NOCATDSNS	Uncataloged data sets are not protected from access
Warning	SETROPTS CATDSNS(WARNING)	Access to uncataloged data sets is permitted but generates a warning
Yes/Fail	SETROPTS CATDSNS(FAILURES)	Access to uncataloged data sets is only permitted for started tasks and SPECIAL users. Access for other users is not permitted.

This field supports overtype.

CKRSITE_CLASS

This text field indicates the general resource class that was specified in the CKRSITE module that was active at the moment the CKFREEZE file was created.

CMDVIOL

This RACF flag indicates whether RACF is to log violations detected by RACF commands (due to a SETROPTS CMDVIOL command). If set (CMDVIOL=YES), command violations are logged. This field supports overtype.

COLLECTDATE

A string of 17 characters containing the time stamp of the zSecure Collect file for the current system, in the format `DD MMM YYYY HH:MM`, indicating day, month, year, and time.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPATMODE

This RACF flag indicates whether RACF is to allow users and jobs that do not have security labels on a system enforcing security labels (due to a SETROPTS COMPATMODE command). If set (COMPATMODE=YES), RACF allows users and jobs without security labels. This field supports overtype.

COMPLEX

The security complex that contains the system. This can come from the ALLOC COMPLEX parameter or default to a system name.

CON_AMRF

This flag field indicates whether the Action Message Retention Facility (AMRF) is active. This is specified by the INIT,AMRF parameter in parmlib member CONSOLxx. If set, action messages are kept in a buffer, so that they can be review using the DISPLAY R,M command.

CON_CMDDELIM

This field contains the installation's command delimiter. This is specified by the INIT,CMDDELIM parameter in parmlib member CONSOLxx.

CON_CONSOL

Contains the parmlib CONSOL*xx* member suffix for reading console, syslog, and hardcopy definitions. For example, `CON_CONSOL=00` indicates parmlib member `CONSOL00`.) The parmlib member suffix is specified by the `CON` parameter of parmlib member `IEASYS`*xx*.

Logically, the `CON` parameter contains the active setting, while the IPL specification is in `IPLPARM_CON`. However, because the `CON` parameter is not dynamic the values are the same.

CON_DFLT_ROUT

This field indicates the default routing codes for messages that do not have routing information. This is specified by the DEFAULT,ROUTCODE parameter in parmlib member CONSOLxx.

CON_HCPY_CMDLVL

This field contains the type of commands to be recorded on hardcopy. This is specified by the HARDCOPY,CMDLEVEL parameter in parmlib member CONSOLxx. Table 554 on page 1433 lists the possible values for this field.

Table 554. Types of commands that can be recorded in printed output

Value	Meaning
CMDS	Operator commands, system commands, responses, static status displays, and time-interval updates status displays are logged.
INCMDS	Operator commands, system commands, and responses are logged.
NOCMDS	No commands, responses, or status displays are logged.
STCMDS	Operator commands, system commands, responses, and static status displays are logged.

CON_HCPY_DEVNUM

This field indicates whether the hardcopy log is sent to syslog (*SYSLOG*) or to a hardcopy log device (*nnn*). The device number value is taken from the HARDCOPY,DEVNUM parameter in parmlib member CONSOL*xx*. It is not the actual device number.

CON_HCPY_ROUT

Indicates the message routing codes the hardcopy log is to receive. This value is specified by the HARDCOPY,ROUTCODE parameter in parmlib member CONSOLxx.

CON_LOGON_AUTO

This flag field indicates whether a logon is automatic for the system consoles. This is specified by the DEFAULT,LOGON parameter of parmlib member CONSOLxx. If set, each console that is activated is logged on using the console's name as userid.

CON_LOGON_REQ

This flag field indicates whether a logon is required for the system consoles. This is specified by the DEFAULT,LOGON parameter of parmlib member CONSOLxx. If not set, no logon is required for system consoles; if any system console resides in a physically insecure area, this is a security exposure. B1 security requires a logon.

CON_MLIM

This field indicates the maximum number of buffers that can be used for WTO messages. This is specified by the INIT,MLIM parameter in parmlib member CONSOLxx.

CON_MON_DSNAME

This flag field indicates whether the system adds information on the first non-temporary data set allocated on a DASD volume to mount messages displayed on consoles. This is specified by the INIT,MONITOR parameter in parmlib member CONSOLxx.

CON_MON_SPACE

This flag field indicates whether the system adds information on the space available on a DASD volume to mount messages displayed on consoles. This is specified by the INIT,MONITOR parameter in parmlib member CONSOLxx.

CON_MONITOR

This field shows the events that must be monitored for the purpose of automation, like JOBNAMES, SESSION, and STATUS. It is set by the MVS command SETCON MONITOR. The MONITOR option allows you to receive monitored messages for automation purposes without requiring that the

messages be queued to a console or be written to SYSLOG or OPERLOG. This field can be displayed with output formats MONITOR and $MONITOR; the default format is MONITOR and the default output width is 5.

CON_MPFLST

This field contains the parmlib MPFLSTxx member suffix used to read Message Processing Facility (MPF) definitions. (Value <pv>00</pv> indicates parmlib member MPFLST00.) This is specified using the INIT,MPF parameter of parmlib member CONSOLxx.

You can specify multiple MPFLSTxx members. You can also display the MPFLSTxx members used using the MPF report.

CON_MSG_LOSS

This flag field indicates whether messages have been lost somewhere in the sysplex. If set, the message procedures can be in error, and the events described by the messages cannot be audited using the system log.

CON_PFKTAB

This field contains the parmlib PFKTABxx member suffix used to read console function key definitions. (Value <pv>00</pv> indicates parmlib member PFKTAB00.) This is specified using the INIT,PFK parameter of parmlib member CONSOLxx.

CON_RLIM

This field indicates the maximum number of buffers that can be used for WTOR messages. This is specified by the INIT,RLIM parameter in parmlib member CONSOLxx.

CON_UEXIT

This flag field indicates whether the WTO(R) installation exit IEAVMXIT is to be active. This is specified by the INIT,UEXIT parameter in parmlib member CONSOLxx.

CPU_MODEL_BYTE

This parameter identifies the two–character CPU model byte, a model within the CPU_TYPE. This is not the model as it can be found in brochures, but the byte as it is returned by the hardware.

If the data is generated by an APF-Authorized zSecure Collect program run on MVS, the program usually obtains the model byte value from VM.

To get the correct value for the model byte, you need a CKFREEZE file created by an APF-authorized run of the zSecure Collect program which retrieves the actual model data from the system.

If you do not use such a CKFREEZE file or obtain the value from a non-APF authorized CARLa query (run from the zSecure product panel, for example) and your z/OS system runs on a virtual machine, the CPU_MODEL_BYTE value returned is `FF`. This value represents the z/VM model byte for a virtual machine, not the actual model for the z/OS system.

CPU_MODEL_NAME

Contains the CPU model identification as reported by the CSRSI service. The value is typically shown in the following format: *`manufacturer type`* `model` *`model`*. The value is missing on systems that do not have the CSRSI service.

CPU_SERIAL

5 character CPU serial. This number is usually a unique number within machines with the same CPU_TYPE. For certain CPU types, the model can be set by the customer (for example, a P/390). For a machine with LPARs or their OEM equivalent, the first digit usually identifies the LPAR number. The processor number (the first digit of the hardware processor serial number - LPAR is the second digit) is not reported.

CPU_TYPE

4 character CPU type as returned by the processor hardware.

DATE_OFFSET

Returns the offset between the UTC date and the local date as set with the SET DATE system command. The value is specified in number of days.

DASDVOL

This RACF flag indicates whether the DASDVOL class is active. If set (DASDVOL=YES), users that do not have ALTER access to a data set are still able to alter, rename, delete, dump and restore the data set if they have access to a profile in the DASDVOL class for the volume containing the data set.

DEVSUP_TAPEAUTHDSN

This flag indicates how DFSMS issues SAF calls to verify authorization to a tape data set. If this flag is on, SAF calls are issued in the DATASET class that are identical to those issued if the data set resided on DASD (except for the volume serial). If this flag is off, SAF calls are issued with the DSTYPE=T option set, which means that special tape protection options come into play.

DEVSUP_TAPEAUTHF1

Flag field that indicates ifDFSMS issues an additional SAF call to verify authorization to the first data set on a tape when accessing another data set residing on the tape.

DFPLEVEL

A string that indicates the software level of Data Facility Product (DFP) . For Data Facility Storage Management Subsystems (DFSMS), the DFP level is stabilized to level 3.3.1.

DEVSUP_TAPEAUTHRC4

This string, which can be ALLOW or FAIL, indicates whether DFSMS denies access to data sets that are not protected by a security profile when TAPEAUTHDSN or TAPEAUTHF1 are in effect.

DEVSUP_TAPEAUTHRC8

String that indicates whether DFSMS is running in warning mode when the `TAPEAUTHDSN` or `TAPEAUTHF1` setting is specified. This setting can have the following values:

- WARN means that access is permitted to data sets that typically cannot be accessed. Your security product reports the access as a violation. However, the `OPEN` and `EOV` actions are permitted.
- `FAIL` means that the access attempts fail.

DLOGOPT

Auditing options for data sets (RACFclass=DATASET), due to a SETROPTS LOGOPTIONS command. The DLOGOPT values and the SETROPTS LOGOPTIONS auditing level are documented in the table below.

DLOGOPT value	SETROPTS LOGOPTIONS auditing level
Always	ALWAYS
Failure	FAILURES
Never	NEVER
Profile	(determined by profile)
Success	SUCCESSES

Use the LOGOPT field of NEWLIST TYPE=CLASS to display auditing options for all classes.

DMS parameters

Note that for this and all subsequent DMS parameters the value can only be trusted if zSecure Collect was able to find the parameter data set and member. If not, some values are set to the DMS-documented default value and others are simply empty. If some parameters are empty, do not trust the other values.

DMSRACFALWZ

String value that shows value of the DMS RACFALWZ (RACF always-call) parameter. This setting indicates whether RACF support is called for non-indicated data sets. On systems that have DFP, specify `DMSRACFALWZ=Y`

If `DMSRACFALWZ=N`, then data sets that are not RACF-indicated are processed by DMS without further security checking.

If this string is set or if the data set is indicated, the actions of DMS are further determined by the `RACFSUPP` parameter. See the `DMSRACFSUPP` keyword description.

DMSRACFBKUP

String value that shows the `DMS RACFBKUP` (RACF discrete profile backup) parameter. This parameter determines if DMS backs up discrete profiles to a profile with a generated name. The generated name has the format *`userid`*`.jobname.Dyyddd.THMhhmm.TSSssth`, where *`userid`* is the qualifier defined by DMS parameter `RACFUSID` represented by the `DMSRACFUSID` keyword. The possible `DMSRACFBKUP` values and their meaning are defined in the Table 555.

Table 555. SYSTEM NEWLIST TYPE - possible values for the DMSRACFBKUP keyword

DMSRACFBKUP value	Meaning
`F`	DMS never saves profiles.
`N`	DMS never saves profiles at backup and archive.
`Y`	DMS saves profiles for archive but not for backup.

The values `Y` and `F` provide incomplete discrete profile support. Data sets that have a discrete profile during archive/backup cannot be restored.

DMSRACFDVOL

The DMS parameter RACFDVOL shows the volume serial number used in backed up discrete profiles. (See also the DMSRACFBKUP keyword description.

DMSRACFNEWN

The DMS parameter RACFNEWN (RACF new-name) indicates if data sets can be renamed when they are restored. Specifying DMSRACFNEWN=Y results in a security exposure because DMS only checks access on the target (new) data set name, not on the name being restored.

DMSRACFPRED

The DMS parameter RACFPRED indicates whether DMS pre-defined discrete profiles are used during restore.

DMSRACFPROC

Indicates if the DMS/OS RACF interface for RACF processing is activated.

- DMSRACFPROC=Y indicates that DMS bypasses RACF-indicated data sets without a profile. If the setting DMSRACFALWZ=Y is also specified, DMS bypasses all data sets without a profile.
- DMSRACFPROC=N indicates that DMS processes RACF-indicated data sets even if no profile exists. If the setting DMSRACFALWZ=Y is also specified, DMS process all data sets even if no profile exists.

DMSRACFSUPP

This DMS parameter indicates whether DMS processes data sets ('RACF Support'). If not set (DMSRACFSUPP=N), RACF-indicated data sets (or all data sets if RACFALWZ=Y) are *not* processed (for example, they are not restored or backed up). If set (DMSRACFSUPP=Y), processing depends on the DMS parameter RACFPROC (see field DMSRACFPROC).

DMSRACFUSID

This DMS parameter RACFUSID shows the first qualifier used for backup-discrete profiles. Recommended is a revoked userid (not group id) without the GRPACC attribute.

DMS_SECURE_PARMLIB

Flag field that indicates if the site security setting for DMS PARMLIBs is turned on.

- If DMS PARMLIB=Y, the site has restricted the use of DMS PARMLIBs to a set of specific data set names using the DMS Security Parmlib feature. This flag is set in the load module ADSTS148 together with an authorized parmlib data set name.
- If DMS PARMLIB=N or the value is not specified, it indicates a major security loophole that permits any user to deactivate RACF processing in DMS, bypassing RACF security.

DMSSECURVOL

This DMS parameter indicates whether DMS is to use the RACF DASDVOL class. If set to 'Y' DMS first checks DASDVOL authority before it checks data set-level authority. If DASDVOL authority is granted, no further checks are performed.

DYNAMIC_CDT

Indicates if the dynamic class descriptor table (CDT) feature of RACF is active on the system. On systems not running RACF the field is missing.

EARLYVERIFY

This flag indicates whether JES is to call the system authorization facility (SAF) for jobs that do not qualify for userid propagation. If set to EARLYVERIFY=YES, JES verifies the user id, group, and password at job submission time. For JES2 3.1.3 and later, this flag is not tested and job processing occurs as if the value

was YES. The option indicated by this flag can be set by a SETROPTS JES(EARLYVERIFY) command. This field supports overtype.

EGN

Flag field that indicates if enhanced generic naming (EGN) is in effect due to a SETROPTS EGN command. This field supports overtype.

EIMREGISTRY

For z/OS 1.4 and z/OS 1.5, this field contains the name of the RACF registry of this system in the EIM domain. For those releases only, the value is set at IPL, or whenever SETROPTS EIMREGISTRY is issued. The value is obtained from the FACILITY profile IRR.PROXY.DEFAULTS.

On z/OS 1.6 and higher, RACF does no longer maintain an in-storage pointer to the registry name, and the EIMREGISTRY field is missing. It is the responsibility of the EIM registry application to obtain the EIM environment information (which includes the registry name) from the FACILITY profile.

ERASEONSCRATCH, EOS

This string indicates whether erase-on-scratch is in effect (due to a SETROPTS ERASE command). If in effect, data sets are physically erased when deleted or released for reuse. The ERASEONSCRATCH values and their meaning are documented in the following table. This field is only present on a RACF system.

ERASEONSCRATCH value	Meaning
All	All data sets are physically erased after delete (due to a SETROPTS ERASE(ALL) command)
Lvlnnn	Physical erasure is performed if the profile that protects the data set specifies ERASE or if the profile's security level is equal to or greater than the erase security level *nnn* as specified on the SETROPTS ERASE(SECLEVEL) command.
None	No data sets are physically erased after delete, even if the erase indicator in the data set profile is on as a result of a SETROPTS NOERASE command.
Profile	The erase indicator in the data set profile is used to determine whether the data set is physically erased after delete as a result of a SETROPTS ERASE(NOSECLEVEL) command.

Note that, when migrated or backed up data sets are scratched from HSM owned DASD volumes, the field HSMERASE determines if HSM actually performs the erasure requested by the profile.

ERASESECLEVEL, SECLEVELERASE

String value that indicates the security level at or above which all data sets are physically erased when deleted or released for reuse as a result of a SETROPTS ERASE(SECLEVEL) command. If the value is *None*, the ERASEONSCRATCH field determines erasure options. Otherwise, this field contains a number. This field is only present on a RACF system.

ESMNAME

Name of the active external security manager.

ESMLVL, ESMLEVEL

The release level of the active external security manager. For RACF, this field also contains IRRDPSDS (dynamic parse) APAR level, IRRTEMP1 (RACF templates) APAR level, and, if available, the numerical equivalents of release level and APAR level.

FORCE24, BELOW

This flag indicates whether all ACEEs reside below the 16 MB line (in 24-bit addressable memory). It is set if one or more exits reside below the 16 MB line.

GENANC_JOBCOUNT

This field is part of a repeat group. It shows the number of generic anchors that RACF maintains for jobs matching the associated JOBNAME value. This field can be specified using the RACF SET GENERICANCHOR command.

GENANC_JOBNAME

This field is part of a repeat group that shows the number of generic anchors RACF maintains for jobs matching the JOBNAME value. This field can be specified using a RACF SET GENERICANCHOR command. Job names with an (*) as the last character specify a set of similarly named jobs.

GENANC_SYSTEM_COUNT

Contains the number of generic anchors that RACF maintains for any job for which no applicable JOBNAME has been specified in a RACF SET GENERICANCHOR command.

GENERICOWNER, GENOWN

This flag indicates whether restrictions on the creation of generic profiles are in effect (due to a SETROPTS GENERICOWNER command). If set (GENERICOWNER=YES), users can only create a generic profile more specific than any existing profile covering the same generic resource if:

- The user has the SPECIAL attribute
- The user is the owner of the existing profile
- The profile is owned by a group and the user is group-SPECIAL in that group.
- The profile is owned by a user in a group and the current user is group-SPECIAL in that group.

This option does *not* apply to the class DATASET; for class DATASET, the CREATE authority determines who can create profiles. This field supports overtype. This field is only present on a RACF system.

GRPLIST, LISTGRP

Flag field that indicates if list-of-groups processing is in effect as a result of SETROPTS GRPLIST command. If set (GRPLIST=YES), user authority to a resource is not based only on the authority of the user's current connect group but also on the highest authority of all groups the user is connected to. This field supports overtype. This field is only present on a RACF system.

HISTORY, PWDHISTORY

This string indicates the number of previous passwords stored by RACF (due to a SETROPTS PASSWORD(HISTORY) command). If set to '**No**', no password history is kept; otherwise, it contains a number in the range 1 to 32. This field supports overtype.

HSMBACKUPPREFIX

This string indicates the prefix of the data set name HSM generates when it backs up a data set. If not set, HSM uses the userid specified in the HSM startup procedure.

This field is determined by the BACKUPPREFIX parameter of the HSM SETSYS command.

This repeated field is reported once for every instance of DFSMShsm started on the system.

HSMERASE

Flag field that indicates ifHSM asks RACF for the erase status of the user data set when backed up or migrated data sets are scratched from HSM-owned DASD volumes. If this flag is not set (HSMERASE=NO) and the ERASEONSCRATCH field is set to erasure, this indicates a security exposure.

This field is determined by the ERASEONSCRATCH parameter of the HSM SETSYS command.

This repeated field is reported once for every instance of DFSMShsm started on the system.

HSMJOBNAME

This repeated field contains the job names for identifying the DFSMShsm instances started on the system

HSMLEVEL, HSMLVL

String indicating the software level of HSM. This repeated field is reported once for every instance of DFSMShsmstarted on the system.

HSMMIGRATEPREFIX

This string indicates the prefix of the data set name HSM generates when it migrates a data set. If not set, HSM uses the userid specified in the HSM startup procedure.

This field is determined by the MIGRATEPREFIX parameter of the HSM SETSYS command.

This repeated field is reported once for every instance of DFSMShsm started on the system.

HSMMULTITAPEVOL

Flag field that indicates if HSM uses more than one TAPEVOL profile to protect the volume pool. This flag is not used in recent HSM releases. This repeated field is reported once for every instance of DFSMShsm started on the system.

HSMPROFILEBACKUP, HSMBACKUPPROFILE

This flag indicates whether HSM creates a backup RACF discrete profile when it backs up a cataloged RACF-indicated data set.

This field is determined by the PROFILEBACKUP parameter of the HSM SETSYS command.

This repeated field is reported once for every instance of DFSMShsm started on the system.

HSMRACFIND

Flag field that indicates if RACF is to put RACF-indication on migrated and backed up data sets. Specify HSMRACFIND=YES unless all of the following conditions are met:

- RACF always-call is in effect.
- Generic profile checking is in effect.
- Generic profiles have been defined that cover the migration and backup qualifiers.

The value for the HSMRACFIND setting is determined by the RACFIND parameter of the HSM SETSYS command.

HSMRACFIND is a repeated field that is reported once for every instance of DFSMShsm started on the system.

HSMSMFRECNO

This field indicates the SMF record type used for HSM daily and volume statistics records; HSM function statistics have SMF record type HSMSMFRECNO+1. If "No", HSM does not write SMF records or HSM is not active on this system.

This field is determined by the SMF parameter of the HSM SETSYS command.

This repeated field is reported once for every instance of DFSMShsm started on the system.

HSMTAPESECURITY

This field contains the DFSMShsm tape security setting, as described in the DFSMShsm diagnosis Reference, offset 437 in the MCVT.

HSMTAPESELVOL

Flag field that indicates if HSM is to allocate new tapes from its own pool or from the system scratch tapes.

This field is determined by the SELECTVOLUME parameter of the HSM SETSYS command.

This repeated field is reported once for every instance of DFSMShsm started on the system.

HWNAME

This string contains the hardware name.

IKJTSO

This string contains the current source for TSO parameters. It has the form IKJTSO**xx** if the source for TSO parameters is parmlib member IKJTSO**xx**; it is set to PARMLIB if the TSO options have been changed online by the PARMLIB command.

INACTIVE

This string indicates the number of days that a userid remains valid without being used (due to a SETROPTS INACTIVE command). If set to '**No**', users are never revoked because of lack of activity; otherwise, it contains a number in the range 1 to 255. This field is only present on a RACF system.

Note that inactive users are only revoked by RACF the next time user activity is attempted, for instance the next time the now inactive user tries to logon. Inactive users can be found using the CARLa script CKRLINAC. This field supports overtype.

INITSTATS

Flag field that indicates if RACF statistics are updated by RACINIT processing (due to a SETROPTS INITSTATS command). This field supports overtype.

INTERVAL, PWDINTERVAL

This string indicates the maximum number of days a password remains valid (due to a SETROPTS PASSWORD(INTERVAL) command). If set to '**No**', passwords never expire; otherwise, it contains a number in the range 1 to 254. This field supports overtype. This field is only present on a RACF system.

IODF_CONFIG_DATE

The date the active IODF configuration was last updated. For detailed instructions on how to use this field in SELECT/EXCLUDE specifications, see "Date fields" on page 903.

IODF_CONFIG_ID

This string contains the name of the configuration selected from those defined in the IODF.

IODF_CONFIG_TIME

The time the active IODF configuration was last updated. This field can only be used for output, and not for SELECT/EXCLUDE processing.

IPLDATE

The date the system was last IPLed, in the format 'DD MMM YYYY'. For detailed instructions on how to use this field in SELECT/EXCLUDE specifications, see "Date fields" on page 903.

IPLDEV

This string indicates the device number of the IPL device. The value returned has four characters. The first character returned might be a blank if the value is a three-digit device number.

IPLPARM parameters

For further information on these variables, refer to the z/OS MVS Initialization and Tuning Reference, especially the section that documents the (system initialization parmlib member `IEASYS`*`xx`*. The effective parmlib specification at IPL time can be found in IPLPARM_LOAD; also check IPLPARM_PARMLIB_LOAD. Note that IEASYS00 is always processed first, followed by any `IEASYS`*`xx`* members with the suffixes documented in IPLPARM_SYSP These IEASYSxx members might override earlier parameter specifications. The parameter specifications might be updated several times during the IPL process. The last, and therefore the effective, parameter specification at IPL time is documented in the IPLPARM variables. Some parameters can be updated dynamically after IPL using system commands such as SET and SETPROG. The results from these actions are not shown in the IPLPARM variables.

IPLPARM_ALLOC

This string contains the list of suffixes passed at IPL time that specifies the names of the ALLOCxx parmlib members. These members describe installation defaults for allocation parameters. Value `00` indicates parmlib member ALLOC00. This setting can also be specified using the ALLOC parameter of parmlib member `IEASYS`*`xx`*.

IPLPARM_APF

Contains the suffix passed at IPL time that specifies the name of the `IEAAPF`*`xx`* parmlib member. This member contains authorized library names. Value `00`

indicates parmlib member IEAAPF00. This setting can also be specified using the APF parameter of parmlib member IEASYS*xx*.

IPLPARM_AUTOR
String field that contains the list of suffixes at IPL time that specify the names of the AUTOR*xx* parmlib members. These members contain the auto-reply policy for WTOR messages. This suffix is specified using the AUTOR parameter of parmlib member IEASYS*xx*.

IPLPARM_AXR

The IPLPARM_AXR field is a string field that contains the suffix that completed the name of the parmlib member AXR*xx* at system IPL. Parmlib member AXR*xx* contains system REXX parameters. (Value 00 indicates the parmlib member AXR00.) This suffix is specified using the AXR parameter of parmlib member IEASYS*xx*.

IPLPARM_CATALOG

This string contains a list of suffixes passed at system IPL that specify the names of IGGCAT*xx* parmlib members. These members can be used to define catalog system parameters. Value 00 indicates parmlib member IGGCAT00. This setting can also be specified by using the CATALOG parameter of parmlib member IEASYS*xx*.

IPLPARM_CEE

This string contains a list of suffixes passed at IPL time that specifies the names of the CEEPRMxx parmlib members. These members are used to provide default Language Environment run-time options for the system. Value 00 indicates parmlib member CEEPRM00). This setting can also be specified using the CEE parameter of parmlib member IEASYS*xx*.

IPLPARM_CLOCK

This string contains the parameters passed at IPL time that specify the name of the CLOCKxx parmlib member. This parmlib member indicates whether to prompt the operator to set the TOD clock during system initialization, specifies the time zone, and controls ETR usage. Value 00 indicates parmlib member CLOCK00.

This setting can also be specified using the CLOCK parameter of parmlib member IEASYS*xx*.

IPLPARM_CLPA

Flag field that indicates if the last IPL explicitly requested loading the LPA from the LPALST concatenation. This request is always occurs implicitly on a cold start. However, sometimes the explicit specification in an IEASYS*xx* member does not always show up. As a result, the value for IPLPARM_CLPA setting is shown as *YES* or blank by default, not as *NO*.

When IPLPARM_CLPA=YES, it also implies that the IPLPARM_CVIO value is *YES*, which means that previous VIO data set pages are purged.

The IPLPARM_CLPA setting can also be specified using the CLPA parameter of parmlib member IEASYS*xx*.

IPLPARM_CMB

This string contains the list of the I/O device class parameters passed at IPL time for which measurement data is collected (besides the DASD and tape device classes). This setting can also be specified via the CMB parameter of parmlib member IEASYS*xx*.

IPLPARM_CMD

This string contains a list of parameters passed at IPL time that specifies the names of the COMMND*xx* parmlib members. These members contain automatic operator commands to be issued during master scheduler initialization. Value `00` indicates parmlib member COMMND00.

This setting can also be specified using the CMD parameter of parmlib member IEASYSxx.

IPLPARM_CON

This string contains the suffix passed at IPL time that specifies the name of the CONSOLxx parmlib member. This member contains console, syslog and hardcopy definitions. Value `00` specifies parmlib member CONSOL00, The value NONE specifies that the IBM default values be used for the definitions so that message routing is determined by the IMSI values specified during initialization. Adding the NOJES3 keyword to the string allows JES2 functions incompatible with JES3 to operate successfully when JES3 is installed but not in use. If the string contains NOJES3 only, NONE is implied and the system uses the IBM default values. These settings can also be specified using the `CON` parameter of parmlib member `IEASYS`*`xx`*. Logically, this field contains the IPL specification, while the active setting is in `CON_CONSOL`. However, the `CON_CONSOL` parameter is not dynamic, the values are the same.

IPLPARM_COUPLE

This string contains the suffix passed at IPL time that specifies the name of the COUPLExx parmlib member. This member describes the sysplex environment for the initializing system. Value `00` indicates parmlib member COUPLE00.

This setting can also be specified using the COUPLE parameter of parmlib member `IEASYS`*`xx`*.

IPLPARM_CSA

This string contains the sizes of the virtual common service area (CSA) and extended common service area (ECSA) as specified at IPL time. The default unit for either size is 1 KB blocks.

This setting can also be specified using the CSA parameter of parmlib member `IEASYS`*`xx`*.

IPLPARM_CSCBLOC

This string indicates whether the CSCB control block chain is located above or below the 16 MB line as specified at IPL time.

This setting can also be specified using the CSCBLOC parameter of parmlib member IEASYSxx.

IPLPARM_CVIO

Flag field that indicates if the last IPL explicitly requested that all VIO data set pages be purged from auxiliary storage. This request is implicitly issued on a cold start. However, an explicit specification in an `IEASYS`*`xx`* member does not always show up. As a result, the value for `IPLPARM_CVIO` setting is shown as *`YES`* or blank by default, not as *`NO`*. The setting `IPLPARM_CVIO=YES` is implicitly specified by `IPLPARM_CLPA=`*`YES`*.

The `IPLPARM_CVIO` setting can also be specified using the `CVIO` parameter of parmlib member `IEASYS`*`xx`*.

IPLPARM_DEVSUP

This string contains a list of suffixes passed at IPL time that specifies the names of the DEVSUP*xx* parmlib members. These members specify the installation defaults for device support options. The value 00 indicates parmlib member DEVSUP00.

This setting can also be specified using the DEVSUP parameter of parmlib member IEASYS*xx*.

IPLPARM_DIAG

This string contains a list of suffixes passed at IPL time that specifies the names of the DIAGxx parmlib members. These members control the common storage tracking function and GFS tracing. Value 00 indicates parmlib member DIAG00.)

This setting can also be specified using the DIAG parameter of parmlib member IEASYS*xx*.

IPLPARM_DRMODE

Flag field that indicates if this system has been IPLed as part of a disaster recovery scenario. The setting can be specified via the DRMODE parameter of parmlib member IEASYS*xx*.

IPLPARM_DUMP

This string specifies whether cataloged SYS1.DUMPxx data sets on permanently resident volumes are to be made available on direct-access devices (DASD) or not (NO) at IPL time, and if so optionally a range for the *xx*-suffix, (especially notable in case of DASD shared between systems. The default range is SYS1.DUMP00 through SYS1.DUMP99.

This setting can also be specified using the DUMP parameter of parmlib member IEASYS*xx*.

IPLPARM_DUPLEX

This string contains the name of a paging data set to be used to hold a secondary copy of all common area system pages as specified at IPL time. It is only meaningful on a cold start. That is, if the CLPA parameter was specified or implied. This setting can be specified using the DUPLEX parameter of parmlib member IEASYS*xx*.

IPLPARM_EFFECTIVE

This string contains all effective IPL parameters separately available in the IPLPARM_<parameter> variables, plus possibly obsolete specifications or defaults. See also IPLPARM_OPERATOR. See the separate variables and/or the Initialization and Tuning Reference (section IEASYS*xx*) for further documentation.

IPLPARM_EXIT

This string contains a list of suffixes passed at IPL time that specifies the names of the EXITxx parmlib members. These members contain the entry points and names of allocation installation exits. Value 00 indicates parmlib member EXIT00. This setting can also be specified using the EXIT parameter of parmlib member IEASYS*xx*.

IPLPARM_FIX

This string contains a list of suffixes passed at IPL time that specifies the names of the IEAFIXxx parmlib members. These members contain names of modules to be placed in a fixed LPA that lasts for the duration of the IPL. Value 00 indicates

parmlib member IEAFIX00.) You can also specify the NOPROT keyword to indicate that the fixed LPA is not page-protected.

These settings can also be specified using the FIX parameter of parmlib member IEASYS*xx*. See also IPLPARM_MLPA.

IPLPARM_GRS

This string contains a keyword value indicating whether the system is to participate in a global resource serialization complex or not (NONE), and if so, how, as specified at IPL time.

This setting can also be specified using the GRS parameter of parmlib member IEASYS*xx*.

IPLPARM_GRSCNF

This string contains the suffix passed at IPL time that specifies the name of the GRSCNFxx parmlib member. This member contains essential configuration information for a system to participate in a global resource serialization complex. This specification is not used if GRS=NONE is present at IPL time, and might be absent if GRS=STAR is specified. If no suffix is specified, the value defaults to 00 to indicate parmlib member GRSCNF00.

This setting can also be specified using the GRSCNF parameter of parmlib member IEASYS*xx*.

IPLPARM_GRSRNL

This string contains a list of suffixes passed at IPL time that specifies the names of the GRSRNLxx parmlib members. These members contain the resource name lists (RNLs) to be used for global resource serialization. Value <pv>00</pv> indicates parmlib member GRSRNL00. You can also specify the EXCLUDE keyword to indicate no RNLs are to be used at all. This setting can also be specified using the GRSRNL parameter of parmlib member IEASYS*xx*.

IPLPARM_HVCOMMON

This string contains the size of the 64-bit common area. The value is expressed in G or T, meaning gigabyte and terabyte respectively. The default setting is 64 GB. This setting can also be specified using the HVCOMMON parameter of parmlib member IEASYS*xx*.

IPLPARM_HVSHARE

This string contains the amount of virtual storage that can be shared. The value is expressed in G, T, or P, meaning gigabyte, terabyte, and petabyte respectively. If the value equals '0' (without G, T, or P) the default setting of 510 TB is used. This setting can be specified using the HVSHARE parameter of parmlib member IEASYSxx.

IPLPARM_ICS

This string contains the suffix passed at IPL time that specifies the name of the IEAICSxx parmlib member. This member contains the installation control specification used by the system resources manager to assign performance groups. Value 00 indicates parmlib member IEAICS00. This setting can also be specified using the ICS parameter of parmlib member IEASYS*xx*.

IPLPARM_IKJTSO

This string contains the suffix passed at IPL time that specifies the name of the IKJTSOxx parmlib member . This member contains the TSO/E settings for the system. This setting can also be specified using the IKJTSO parameter of parmlib member IEASYSxx.

IPLPARM_ILMLIB

String that defines the data set for the IBM Tivoli License Compliance Manager (TLCM). The default ILMLIB data set is SYS1.ILMLIB.S&SYSNAME(-7:7). You can also specify NODATASET. See also the IPLPARM_ILMMODE keyword.

IPLPARM_ILMMODE

Text string that specifies the settings for the ILMMODE at IPL time. ILM is the IBM Tivoli License Compliance Manager. The available modes are FIRSTIPL, NORMAL, and EMERGENCY. These settings can also be specified using the ILMMODE parameter of parmlib member IEASYS*xx*. See also the IPLPARM_ILMLIB keyword.

IPLPARM_IOS

String that contains the suffix passed at IPL time. The suffix specifies the name of the IECIOS*xx* parmlib member. This member contains control statements for the I/O supervisor. Value 00 indicates parmlib member IECIOS00. This setting can also be specified using the IOS parameter of parmlib member IEASYS*xx*.

IPLPARM_IPS

This string contains the suffix passed at IPL time that specifies the name of the IEAIPSxx parmlib member. This member contains the installation performance specification to be used by the system resources manager. Value 00 indicates parmlib member IEAIPS00.

This setting can also be specified using the IPS parameter of parmlib member IEASYS*xx*.

IPLPARM_IXGCNF

This string contains a list of suffixes passed at system IPL that specify the names of the IXGCNF*xx* parmlib members. These members can be used to control tracing and monitor intervals for the z/OS system logger. Value 00 indicates parmlib member IXGCNF00. This setting can also be specified by using the IXGCNF parameter of parmlib member IEASYS*xx*.

IPLPARM_LFAREA

This string contains the amount of real storage to be made available for 1 MB pages. The value can be expressed as a percentage of all online real storage available at IPL time, or in M or G meaning megabyte and gigabyte respectively. The default is none, which means that no LFAREA is defined. This setting can also be specified using LFAREA parameter of parmlib member IEASYSxx.

IPLPARM_LICENSE

This text string specifies the setting for what operating system is licensed at IPL time , z/OS or z/OSe, for example. This setting can be specified using the LICENSE parameter of parmlib member IEASYS*xx*.

IPLPARM_LNK

This string contains a list of suffixes passed at IPL time that specifies the names of the LNKLST*xx*parmlib members. These members contain names of data sets to be concatenated to SYS1.LINKLIB to form the LNKLST concatenation. Value <pv>00</pv> indicates parmlib member LNKLST00. In addition to the names specified, SYS1.MIGLIB and SYS1.CSSLIB are concatenated. This specification is

ignored if you specify the LNKLST ACTIVATE statement in a PROG*xx* member. See the IPLPARM_PROG keyword description.

The PROG*xx* member can also specify alternates for the SYS1 data sets mentioned above. This setting can also be specified using the LNK parameter of parmlib member IEASYS*xx*.

IPLPARM_LNKAUTH

Flag field that indicates if the last IPL explicitly requested to treat all libraries in the LNKLST concatenation as APF-authorized when accessed as part of that concatenation, or only those named in the APF table (APFTAB).

This setting can also be specified using the LNKAUTH parameter of parmlib member IEASYS*xx*. Logically, this field contains the IPL specification, while the active setting is in the LNKAUTH parameter (without the prefix). However, the LNKAUTH parameter is not dynamic, so the values are the same.

IPLPARM_LOAD

Repeat group that lists the effective LOAD*xx* cards. This list does not contain filter cards HWNAME, LPARNAME, VMUSERID, and no cards unless selected by the filter cards. Furthermore, the PARMLIB cards differ from those in the LOAD*xx* member in the following ways:

- If a card with the default is added, the text string *Default* is shown as a comment behind the actual 72-character card.
- Volume serials like ****** and **MCAT** have been resolved. This is indicated by the text string *Volume from catalog*.

If a data set error occurs, the comment field includes the text string *Failed* followed by an indication of what operation failed: LOCATE, MOUNT, or OPEN.

IPLPARM_LOGCLS

This string contains the JES output class for the log data sets as specified at IPL time. A log data set is queued to this class when its limit has been reached. See 1448.

This setting can also be specified using the LOGCLS parameter of parmlib member IEASYS*xx*. Logically, this field contains the IPL specification when the active setting is in SYSLOG_CLASS. However, the SYSLOG_CLASS parameter is not dynamic, so the values are the same.

IPLPARM_LOGLMT

Indicates the maximum number of messages permitted for each log data set as specified at IPL time. When this limit is reached, the log data set is closed and queued to JES, and a new log data set is used. This value is also specified by the LOGLMT parameter of parmlib member IEASYS*xx*. The value must be a six-digit number with leading zeroes. Logically, this LOGLMT parameter contains the IPL specification, while the active setting is in SYSLOG_LIMIT parameter. However, the LOGLMT parameter is not dynamic, so the values are the same.

IPLPARM_LOGREC

String that specifies the logrec recording medium for error and environmental recording as specified at IPL time. The value is either the name of the data set for logging or one of the following reserved keywords:

- LOGSTREAM specifies that logging is directed to the sysplex-wide repository SYSPLEX.LOGREC.ALLRECS
- *IGNORE* specifies do not record.

The IPLPARM_LOGREC setting can also be specified by theLOGREC parameter of parmlib member of IEASYS*xx*.The logrec recording medium specification can also be altered by the SETLOGRC command.

IPLPARM_LPA

This string contains a list of suffixes passed at IPL time that specifies the names of the LPALST*xx* parmlib members. These members contain the names of the data sets to be concatenated to SYS1.LPALIB to form the LPALST concatenation. Value *00* indicates parmlib member LPALST00.) You can optionally specify an alternate data set for SYS1.LPALIB using the PROG*xx* parmlib member. This setting can also be specified using the LPA parameter of parmlib member IEASYS*xx*. See also the IPLPARM_PROG and IPLPARM_MLPA keywords.

IPLPARM_MAXCAD

This string contains the maximum number of SCOPE=COMMON data spaces as specified at IPL time. This setting can also be specified using the MAXCAD parameter of parmlib member IEASYS*xx*.

IPLPARM_MAXUSER

This string contains a value that is in principle the maximum number of concurrent jobs and started tasks as specified at IPL time. There are some exceptional conditions when the actual limit is higher: see IPLPARM_RSVNONR and IPLPARM_RSVSTRT. This setting can also be specified using the MAXUSER parameter of parmlib member IEASYS*xx*.

IPLPARM_MLPA

This string contains a list of suffixes passed at IPL time that specifies the names of the IEALPAxx parmlib members. These members contain names of modules to be added to the pageable LPA as an extension that lasts for the duration of the IPL. (Value 00 indicates parmlib member IEALPA00.) In addition, the NOPROT keyword can be present, in which case the extension is not page-protected. These settings can be specified using the MLPA parameter of parmlib member IEASYSxx. See also IPLPARM_FIX and IPLPARM_LPA.

IPLPARM_MSTRJCL, IPLPARM_MSTJCL

This string contains the suffix passed at IPL time that specifies the name of the MSTJCLxx parmlib member. This member contains the JCL used to start the master scheduler address space. Value <pv>00</pv> indicates parmlib member MSTJCL00. This setting can also be specified using the MSTRJCL parameter of parmlib member IEASYS*xx*. See also IPLPARM_MSTRJCL_LINKLIB.

IPLPARM_MSTRJCL_LINKLIB, IPLPARM_MSTJCL_LINKLIB

This flag indicates whether the master JCL was loaded from SYS1.LINKLIB. Normally, the MSTJCL suffix specifies the MSTJCL*xx* member in parmlib, but if the parmlib does not contain that member, the system checks whether link library has a module of that name, and then uses that. If the module cannot be found, the suffix 00 is tried. If that also fails, the operator is prompted to specify the member.

IPLPARM_NONVIO

This repeat group contains the list of local page data sets that have been excluded from direct VIO paging (as long as space is available elsewhere) at IPL time. This setting can also be specified using the NONVIO parameter of parmlib member IEASYSxx.

IPLPARM_NSYSLX

This string contains the number of system linkage indexes to reserve as specified at IPL time. This setting can be specified using the NSYSLX parameter of parmlib member IEASYS*xx*.

IPLPARM_OMVS

This string contains a list of suffixes passed at IPL time that specifies the names of the BPXPRMxx parmlib members. These members contain the OpenEdition MVS (OMVS) configuration specifications. Value 00 indicates parmlib member BPXPRM00). You can specify the keyword DEFAULT to have OMVS start in its minimum configuration mode. This setting can also be specified using the OMVS parameter of parmlib member IEASYS*xx*.

IPLPARM_OPERATOR

This string contains the operator-specified parameters, a subset of the effective IPL parameters. See IPLPARM_EFFECTIVE.

IPLPARM_OPI

Flag field that indicates if the operator was prompted for certain IPL parameters during the last IPL. This setting can also be specified using the OPI parameter of parmlib member IEASYS*xx*.

IPLPARM_OPT

This string contains the suffix passed at IPL time that specifies the name of the IEAOPTxx parmlib member. This member contains parameters for the system resources manager. Value 00 indicates parmlib member IEAOPT00. This setting can also be specified using the OPT parameter of parmlib member IEASYS*xx*.

IPLPARM_PAGE_OPER

This repeat group contains the list of page data sets added by the operator at IPL time. These are added to the page data sets specified in an active IEASYS*xx* parmlib member, until the next cold or quick start.

IPLPARM_PAGE_SYS

This repeat group contains the list of page data sets specified in an IEASYSxx parmlib member at IPL time. This setting can also be specified using the PAGE parameter of parmlib member IEASYS*xx*. If the operator wants to replace the specified data sets, he must specify an alternate IEASYSxx member with the SYSP parameter. To temporarily add Page data sets, the operator can enter a PAGE parameter at the operator prompt.

IPLPARM_PAGTOTL

This string contains a pair of values, the total number of page and swap data sets, as specified at IPL time. This setting can also be specified using the PAGTOTL parameter of parmlib member IEASYS*xx*.

IPLPARM_PAK

This string contains a list of suffixes passed at IPL time that specifies the names of the IEAPAKxx parmlib members. This member contains groups of names of modules in the LPALST concatenation that are processed together or in sequence. Value 00 indicates parmlib member IEAPAK00. This setting can also be specified using the PAK parameter of parmlib member IEASYS*xx*. For the LPALST concatenation, see IPLPARM_LPA.

IPLPARM_PARMLIB_LOAD

This flag indicates that the LOADxx member used contained at least one PARMLIB card at IPL time. If this is not the case, the master JCL is loaded from the IEFPARM DD statement concatenation (or, if this fails, from parmlib). See also IPLPARM_LOAD.

IPLPARM_PLEXCFG

String field that indicates if the system is only permitted to IPL into a certain type of configuration or not (ANY), and if so, which one, as in effect at IPL time. This setting can also be specified using the PLEXCFG parameter of parmlib member IEASYS*xx*.

IPLPARM_PRESCPU

Flag field that indicates if the system brought online all CPUs that were online at the time the IPL was initiated, without regard to the number of CPUs defined to be initially online in the logical partition profile. This setting can also be specified using the PRESCPU parameter of parmlib member IEASYS*xx*.

IPLPARM_PROD

This string contains a list of suffixes that completed at IPL time the names of the IFAPRDxx parmlib members. These members contain the enablement policy for products or product features that can be dynamically enabled under z/OS. Value 00 indicates parmlib member IFAPRD00.

This setting can also be specified using the PROD parameter of parmlib member IEASYS*xx*.

IPLPARM_PROG

This string contains a list of suffixes passed at IPL time that specifies the names of the PROGxx parmlib members. These members specify the format and contents of the APF-authorized library list, the use of exits and exit routines, the standard libraries for the LNKLST and LPALST concatenations, and optionally the LNKLSTxx parmlib members to be used, overriding the LNK parameter. Value 00 indicates parmlib member PROG00.

This setting can also be specified using the PROG parameter of parmlib member IEASYS*xx*.

IPLPARM_RDE

Flag field that indicates if the reliability data extractor feature was specified to be included at IPL time.

This setting can also be specified using the RDE parameter of parmlib member IEASYS*xx*.

IPLPARM_REAL

This string contains a number, the maximum amount of central storage, in 1 KB blocks, that can be allocated for concurrent ADDRSPC=REAL jobs, as specified at IPL time. This setting can also be specified using the REAL parameter of parmlib member IEASYSxx. A nonzero value is a concern, because it enables non-privileged users to run in a key in the 9-15 range, thereby allowing them to alter the contents of CSA, ECSA, SQA, or ESQA storage with this key.

IPLPARM_RER

Flag field that indicates if using the reduced error recovery routines for magnetic tapes was requested at IPL time. This specification is effective only if

the procedures are stated on the OPTCD parameter on a data definition (DD) statement or on the DCB macro. This setting can also be specified using the RER parameter of parmlib member IEASYS*xx*.

IPLPARM_RSU

This string contains the number of central storage increments to be made available for storage reconfiguration, as specified at IPL time. This setting can also be specified via the RSU parameter of parmlib member IEASYS*xx*.

IPLPARM_RSVNONR

This string contains the number of entries in the address space vector table that are to be reserved for replacing entries that are marked non-reusable, as specified at IPL time. This is used to increase the limit specified by the MAXUSER parameter under certain conditions. This setting can also be specified using the RSVNONR parameter of parmlib member IEASYS*xx*. See also IPLPARM_MAXUSER and IPLPARM_RSVSTRT.

IPLPARM_RSVSTRT

This string contains the number of entries in the address space vector table that are to be reserved for address spaces created in response to a START command, as specified at IPL time. This is used to increase the limit specified by the MAXUSER parameter under certain conditions. This setting can also be specified using the RSVSTRT parameter of parmlib member IEASYS*xx*. See also IPLPARM_MAXUSER and IPLPARM_RSVNONR.

IPLPARM_RTLS

This string contains the suffix that completed at IPL time the name of the CSVRTLxx parmlib member. This member contains the run-time library system configuration. Value 00 indicates parmlib member CSVRTL00. This setting can also be specified using the RTLS parameter of parmlib member IEASYS*xx*.

IPLPARM_SCH

This string contains a list of suffixes that completed at IPL time the names of the SCHEDxx parmlib members that contains the master scheduler parameters. Value 00 indicates parmlib member SCHED00. This setting can also be specified using the SCH parameter of parmlib member IEASYS*xx*.

IPLPARM_SMF

This string contains the suffix that completed at IPL time the name of the SMFPRMxx parmlib member. This member contains the SMF parameters. Value 00 indicates parmlib member SMFPRM00. This setting can also be specified using the SMF parameter of parmlib member IEASYS*xx*.

IPLPARM_SMS

This string contains the suffix that completed at IPL time the name of the IDGSMSxx parmlib member. This is the member from which SMS obtains its parameters when the system is initialized with partitioned data set extended (PDSE) support. Value 00 indicates parmlib member IDGSMS00. This setting can also be specified using the SMS parameter of parmlib member IEASYS*xx*.

IPLPARM_SQA

This string contains the (additional) sizes of the virtual system queue area (SQA) and extended system queue area (ESQA) as specified at IPL time. The default unit for either size is 64 KB blocks. This setting can also be specified using the SQA parameter of parmlib member IEASYSxx.

IPLPARM_SSN

This string contains a list of suffixes that completed at IPL time the names of the IEFSSNxx parmlib members. These members contain the information needed to define and initialize selected subsystems. Value 00 indicates parmlib member IEFSSN00.

This setting can also be specified using the SSN parameter of parmlib member IEASYS*xx*.

IPLPARM_SVC

This string contains a list of suffixes that completed at IPL time the names of the IEASVC*xx* parmlib members. These members contain the installation-defined SVCs. Value 00 indicates parmlib member IEASVC00.

This setting can also be specified via the SVC parameter of parmlib member IEASYS*xx*.

IPLPARM_SWAP

This repeat group contains the list of swap data sets specified at IPL time. This setting can also be specified using the SWAP parameter of parmlib member IEASYS*xx*. Note that SWAP works unlike PAGE just as most parameters do, the last specification entirely replaces a previous one. This parameter is no longer supported in z/OS 1.5 and higher, so this field is always missing on those systems.

IPLPARM_SYSNAME

This string contains the name of the system being initialized, as specified at IPL time. This setting can also be specified using the SYSNAME parameter of parmlib member IEASYS*xx*.

IPLPARM_SYSP

This string contains a list of suffixes that completed at IPL time the names of the additional IEASYSxx parmlib members. These members contain system initialization parameters. Value 01 indicates parmlib member IEASYS01. This setting cannot be specified in IEASYS*xx*, but it can be specified using the SYSP parameter at the operator prompt. Note that IEASYS00 is always processed first.

IPLPARM_UNI

This string contains the suffix that completed the name of the parmlib member CUNUNIxx at IPL time. The information stored in CUNUNIxx is used by the Unicode Conversion Services to activate a conversion environment, or delete an inactive conversion environment. This setting can also be specified using the UNI parameter of parmlib member IEASYS*xx*

IPLPARM_VAL

This string contains a list of suffixes that completed at IPL time the names of the parmlib members (VATLSTxx) that contain the volume attribute list. Value 00 indicates parmlib member VATLST00. This setting can also be specified using the VAL parameter of parmlib member IEASYS*xx*.

IPLPARM_VIODSN

This string contains either the name of the VSAM data set for holding information about journaled VIO data sets, or the reserved keyword IGNORE (do not record), as specified at IPL time. This setting can also be specified using the VIODSN parameter of parmlib member IEASYSxx.

IPLPARM_VRREGN

This string contains a number, the default amount of central storage, in 1 KB blocks, to be allocated for concurrent ADDRSPC=REAL jobs, as specified at IPL time. This setting can also be specified using the VRREGN parameter of parmlib member IEASYS*xx*.

IPLPARM_ZZ

The IPLPARM_ZZ flag field indicates whether the ZIIPZAAP system option (or ZZ for short) has been enabled for this system. At system IPL, the ZZ option determines whether the system can perform System z Application Assist Processor (zAAP) processing work using the System z Integrated Information Processor (zIIP) when zAAP processors are not available. This option is specified using the ZZ parameter of parmlib member IEASYSxx.

IPLTIME

The time the system was last IPLed, in the format 'HH:MM'. This field can only be used for output, and not for SELECT/EXCLUDE processing.

IPLVOL

This string contains the name of the IPL volume.

JES2LEVEL, JES2LVL

String indicating the software level of the JES2 or JES3 running as the primary subsystem, e.g. 'SP 4.3.0'.

Currently there is no field which shows whether JES2 or JES3 is the primary subsystem in NEWLIST TYPE=SYSTEM. However, this is reported in message CKR0132 and can also be seen in the subsystem report (NEWLIST TYPE=SUBSYS).

JES2NODE, NODE, NODENAME

This string contains the JES2 node name for the JES2 running as the primary subsystem.

JOBSTEPCAT

Flag field indicating if JOBCAT and STEPCAT DD statements are permitted in jobs. From z/OS 1.5 and up, these DD statements are not permitted in jobs. These DD statements can be enabled or disabled by issuing the following MVS operator commands:

```
MODIFY CATALOG,ENABLE(JOBSTEPCAT)
   MODIFY CATALOG,DISABLE(JOBSTEPCAT)
```

KERBLVL

Contains the value of the SETROPTS KERBLVL setting, indicating the level of Kerberos support present on the system. It controls the types of encryption that can be used when setting up a Kerberos connection.

This field supports overtype on z/OS V1R2 and later. This field is only present on a RACF system.

LNKAUTH

This flag field indicates if all libraries in the linklist are considered APF-authorized, or if only those libraries that are also in the APFlist are considered authorized. If LNKAUTH=YES, all libraries are considered authorized. This setting is also specified by the LNKAUTH parameter in parmlib member IEASYS*xx*.

Note: If set, the libraries in the linklist are only considered authorized when accessed as part of the linklist concatenation. When used in a user-specified STEPLIB, a linklist library is only authorized if it is also part of the APFlist. Logically, this field contains the active setting, while the IPL specification is in IPLPARM_LNKAUTH. However, the IPLPARM_LNKAUTH parameter is not a dynamic parameter, so the values are the same.

LOADPARM

System load parameters as entered on the machine console prior to IPL. Usually consists of IPL device (4 digits), IOC ID (2 digits) and nucleus ID (1 digit). On VM systems running MVS, the device number can differ.

LPAR

Name of the logical partition (LPAR). This is taken from the RMF control blocks and is only present on IBM machines and full compatibles.

LVL1PREF

This string indicates whether RACF protection is in effect for data sets that have single-qualifier names (due to a SETROPTS PREFIX command). If set, it contains a 1- to 8-character first qualifier prefixed to the data set name to get the internal (resource) name. If empty, RACF protection for single-qualifier data sets is not in effect (due to a SETROPTS NOPREFIX command). This field supports overtype.

MEMLIMIT

This field can be used to set an installation wide limit on the virtual storage above the 2 GB line. The default is 0, meaning that no address space can use virtual storage above the line. However, this is a soft limit so every job can override it.

MINCHANGE

This field indicates the minimal number of days that must pass between a user's password changes (due to a SETROPTS PASSWORD(MINCHANGE()) command.) If set to 'No', users can change their passwords more than once on the same day; otherwise, it contains a number in the range 1 to 254. This field supports overtype.

MIXEDCASE

Flag field that indicates if mixed passwords are used as a result of a SETROPTS PASSWORD(MIXEDCASE command. This field supports overtype.

MLACTIVE

This string indicates whether RACF requires security labels to be present on all jobs, all resources defined in USER and DATASET, and all classes defined in the Class Descriptor Table (CDT) that require a security label. It reflects an option set by a SETROPTS MLACTIVE command. The following table documents the MLACTIVE values, the corresponding SETROPTS commands, and their meanings.

MLACTIVE value	SETROPTS command	Meaning
No	SETROPTS NOMLACTIVE	Security labels are not required

MLACTIVE value	SETROPTS command	Meaning
Warning	SETROPTS MLACTIVE(WARNING)	RACF allows jobs without a security label access to resources that do not have a security label, but issues a warning
Yes/Fail	SETROPTS MLACTIVE(FAILURES)	Security labels are required in all normal cases. Privileged started tasks and SPECIAL users are permitted to make requests as long as data is not declassified.
n/a	-	RACF version before 1.9

Classes in the Class Descriptor Table (CDT) that require a security label can be found using the SECLABEL field of NEWLIST TYPE=CLASS. This field supports overtype.

MLALEVEL

The multi-alias level, for example, the number of qualifiers used to look for a user catalog alias pointer in the master catalog.

MLQUIET

Flag field that indicates ifRACF is to keep the system in a tranquil state (due to a SETROPTS MLQUIET command). If set (MLQUIET=YES), only started procedures, console operators, or SPECIAL users are able to logon, start new jobs, or access resources. This field supports overtype.

MLS

This string indicates whether RACF prevents users from declassifying data in a system using security labels. It reflects an option set by a SETROPTS MLS command. The following table documents the MLS values, the corresponding SETROPTS commands, and their meanings.

MLS value	SETROPTS command	Meaning
No	SETROPTS NOMLS	Users are permitted to declassify data
Warning	SETROPTS MLS(WARNING)	Users are permitted to declassify data, but any such action generates a warning message.
Yes/Fail	SETROPTS MLS(FAILURES)	Users are not permitted to declassify data
n/a	-	RACF version before 1.9

This field supports overtype.

MLSTABLE

Flag field that indicates if the system has stabilized security labels (due to a SETROPTS MLSTABLE command). If set (MLSTABLE=YES), security labels can only be altered ifMLQUIET is in effect. This field supports overtype. This field is only present on a RACF system.

MODELGDG

Flag field that indicates if Generation Data Group (GDG) modeling is in effect (due to a SETROPTS MODEL(GDG) command). If set (MODELGDG=YES), the GDG base name, not the GDG generation name, is used to find the data set profile for the data set. This field supports overtype. This field is only present on a RACF system.

MODELGROUP

Flag field that indicates if group modeling is in effect (due to a SETROPTS MODEL(GROUP) command). If set (MODELGROUP=YES), RACF uses a model profile to complete new group-named data set profiles. This field supports overtype.

MODELUSER

Flag field that indicates if user modeling is in effect (due to a SETROPTS MODEL(USER) command). If set (MODELUSER=YES), RACF uses a model profile to complete new data set profiles named with the user ID. This field supports overtype.

MVSIOCID

IO configuration ID selected at IPL. The value '**xx**' indicates that the MVSCP IO configuration data set loaded was taken from SYS1.NUCLEUS members IEANCTxx IOSIITxx, IEFEDTxx, and IOSUCBxx.

MVSLEVEL, MVSLVL

String indicating the software level of MVS, e.g. 'SP4.3.0'.

NJEUSERID

This string indicates the userid to be used for SYSOUT or network jobs that enter the system without an RTOKEN or UTOKEN value. The string value cannot be set to a userid defined in the RACF database. This field supports overtype.

NOADDCREATOR

Flag field that indicates if the system has to suppress the ALTER permit added by default to each newly created profile for the userid of the creator. This field supports overtype. This field is only present on a RACF system.

NODUP

Flag field that indicates if duplicate data set names are permitted. Duplicate data set names are two data sets that both have discrete profiles but reside on different volumes. If set `NODUP=YES`, duplicate data set names are not allowed. The `NODUP` keyword is only supported on RACF systems.

Note: This flag reflects an option that can only be set through module ICHSECOP, not using the SETROPTS command.

OPERAUDIT

Flag field that indicates ifRACF is logging all actions permitted only because a user has the `OPERATIONS` or `group-OPERATIONS` attribute.

The `OPERAUDIT` keyword reflects an option set by the `SETROPTS OPERAUDIT` command. This field supports overtype.

OSLVL

This field returns the version and release of the operating system indicated by the OSNAME field.

OSNAME

This field returns the popular name of the operating system. The version is indicated by the OSLVL field. Also the vendor can be filled in (field OSVENDOR) if the operating system supports that field as a variable.

OSVENDOR

This field returns the company name of the operating system vendor indicated by the OSNAME field if the operating system supports this field as a variable. Otherwise it is blank.

PCMODE

String indicating the mode of RACF program control (as set using the APPLDATA of FACILITY profile IRR.PGMSECURITY). The mode can be 'Basic', 'EnhWarn' or 'Enhanced'. This feature is available in z/OS 1.4 and higher. RACF releases before z/OS 1.4 run in Basic mode.

PRIMARY_LANGUAGE

This field indicates the RACF primary language setting as set by SETROPTR LANGUAGE(PRIMARY()).

PROTECTALL

This string indicates whether RACF protect-all processing is active (due to a SETROPTS PROTECTALL command). The table below documents the PROTECTALL values, the corresponding SETROPTS commands, and their meanings

PROTECTALL value	SETROPTS command	Meaning
No	SETROPTS NOPROTECTALL	Users can access and create data sets that are not RACF-protected
Warning	SETROPTS PROTECTALL(WARNING)	Users can access and create data sets that are not RACF-protected, but any such action results in a warning
Yes/Fail	SETROPTS PROTECTALL(FAILURES)	Normal users are not permitted to access or create data sets that are not RACF-protected. Privileged started tasks and SPECIAL users are allowed to do so, but any such action generates a warning message.

This field supports overtype.

PWDRULE1

This string displays RACF password rule 1. RACF supports 8 different password rules, of which any one can be active or inactive as a result of a SETROPTS PASSWORD(RULE)) command. If active, the password rule is of the form '**Length(min:max) Pattern**' or '**Length(max) Pattern**'. The Pattern is a string of **max** characters indicating what characters are valid at that position; the following table documents the possible character values and their meaning.

Pattern character	Meaning
*	Any character
$	National
A	Alphabetic
C	Consonant
c	Mixed consonant
L	Alphanumeric
m	Mixed numeric
N	Numeric
V	Vowel
v	Mixed vowel
W	No vowel

When multiple password rules are active, RACF attempts to match a new password to any active rules but does not require matching all active rules. As a result, RACF permits a password that is accepted by one rule but not another.

PWDRULE2

This string displays RACF password rule 2. See the PWDRULE1 field.

PWDRULE3

This string displays RACF password rule 3. See the PWDRULE1 field.

PWDRULE4

This string displays RACF password rule 4. See the PWDRULE1 field.

PWDRULE5

This string displays RACF password rule 5. See the PWDRULE1 field.

PWDRULE6

This string displays RACF password rule 6. See the PWDRULE1 field.

PWDRULE7

This string displays RACF password rule 7. See the PWDRULE1 field.

PWDRULE8

This string displays RACF password rule 8. See the PWDRULE1 field.

RACF_AUTOAPPL

This flag field indicates whether RRSF automatically propagates application updates to the RACF database to remote nodes.

You can use the RACF SET AUTOAPPL operator command to specify the application updates options. This command needs to be repeated after each IPL. Therefore, it is normally incorporated in parmlib member IRROPTxx.

RACF_AUTODIRECT

This flag field indicates whether RRSF automatically propagates RACF commands to remote nodes.

You can use the RACF SET AUTODIRECT operator command to specify the automatic command direction options. This command needs to be repeated after each IPL. Therefore, it is normally incorporated in parmlib member IRROPTxx.

RACF_AUTOPWD

This flag field indicates whether RRSF automatically propagates password updates to remote nodes.

You can use the RACF SET AUTOPWD operator command to specify the automatic password direction options. This command needs to be repeated after each IPL. Therefore, it is normally incorporated in parmlib member IRROPTxx.

RACF_JESNODE

Specifies the JES node that is the destination for output that is redirected when the RRSFLIST data set is unusable.

RACF_MLFSOBJ

This string indicates whether RACF requires security labels for files and directories. When the SECLABEL class is active, and MLFSOBJ is active, access to files and directories without security labels is denied except by trusted or privileged started tasks. Since HFS file systems do not fully support security labels (except in read-only mode), conversion to zFS file systems is advisable before turning on this option. This field reflects the option set by a SETROPTS MLFSOBJ(ACTIVE | INACTIVE) command. This field supports overtype.

RACF_MLIPCOBJ

This string indicates whether RACF requires security labels for interprocess communications. When the SECLABEL class is active, and MLIPCOBJ is active, access to semaphores, message queues and shared memory without associated security labels is denied except by trusted or privileged started tasks. This field reflects the option set by a SETROPTS MLIPCOBJ(ACTIVE | INACTIVE) command. This field supports overtype.

RACF_MLNAMES

This string indicates whether the RACF name hiding function is in effect. This function has the following effects:

- Users cannot view the names of z/OS UNIX files and directories that their current security label does not give them authority to read.
- Users cannot view the names of data sets that a mandatory access check followed by a discretionary access check does not allow them to read.
- Users listing catalogs or directories cannot see the names of resources that they cannot currently read.
- Users cannot read a VTOC directly, unless they have been given authorization to the profile in the FACILITY class that protects the VTOC.

This field reflects the option set by a SETROPTS (NO)MLNAMES command. This field supports overtype.

RACF_PWSYNC

This flag field indicates whether RRSF honors the peer-to-peer password synchronization requested by the RACLINK command.

You can use the RACF SET PWSYNC operator command to specify the password synchronization options. This command needs to be repeated after each IPL. Therefore, it is normally incorporated in parmlib member IRROPTxx.

RACF_SECLBYSYSTEM

String that indicates if RACF permits security labels to be activated on a system image basis. When SECLBYSYSTEM is active, the SMF ID values specified in the member list of the profiles in the SECLABEL class determine whether or not

the security label is valid for each system. Security labels that are not valid for a system are considered inactive and cannot be used or listed by users without SPECIAL or AUDITOR on that system. This field reflects the option set by a SETROPTS (NO)SECLBYSYSTEM command. This field supports overtype.

RACF_SUBSYS_PREFIX

The command prefix for routing commands to the RACF subsystem on this system.

RACFACT

Flag field that indicates if RACF is active as a result of the RVARY ACTIVE command.

RACFDBLEVEL

String indicating the template level of the RACF database, for example, 'OA03853 00000010.00000010'.

RACFLEVEL, RACFLVL

A string field that represents the software release level, IRRDPSDS (dynamic parse) APAR level, and IRRTEMP1 (RACF templates) APAR level, as follows:

```
'HRF7730 HRF7730 HRF7730 00000064.00000010'
```

If a CKFREEZE data set produced by earlier versions of zSecure Collect program (CKFCOLL) is used as input, the format is as follows:

```
 '7.7.30  HRF7730 HRF7730 00000064.00000010'
```

This field is often tested by other products.

RACFLOCALNODE

This field returns the node name used by the RACF Remote Sharing Facility (RRSF) for the current system. It is only filled in if a CKFREEZE file of an APF-authorized run of zSecure Collect is being used.

You can use the RACF TARGET LOCAL operator command to specify the local node. This command needs to be repeated after each IPL. Therefore, it is normally incorporated in parmlib member IRROPTxx.

REALDSN

Flag field that indicates if RACF logging uses the real data set name (REALDSN=YES) or the naming-conventions name (REALDSN=NO) for logging purposes. It reflects an option set by the SETROPTS REALDSN command. This field supports overtype.

REFRPROT

This flag returns the status of the REFRPROT option which determines whether refreshable modules from non-APF libraries (REFR modules) are protected from modification. The following values can be returned:

Yes
Indicates that the REFRPROT option is enabled and REFR modules are protected from modification by loading them into Key 0 storage, and page protecting the full pages. This means the modules cannot be modified by key 8 (user key) programs. This is both a RAS (Reliability/Availability/Serviceability) advantage and a minor security advantage. However, setting REFRPROT might cause undesirable side effects for some programs.

No
Indicates that the NOREFRPROT option is enabled and REFR programs are not protected. This is the default setting for this option.

" " blank
Indicates that the REFRPROT option is not available. This option is only available on systems running z/OS version 1.9 and later versions.

The REFRPROT option can be set using the MVS command SETPROG or by specification in the PROGxx member of PARMLIB. For more information, see the *z/OS V1R9.0 MVS Initialization and Tuning Reference*

RETPD

This string specifies the RACF security retention period for tape data sets (due to a SETROPTS RETPD command). It is set to a number in the range 0 to 65533 for a tape data set that expires, and to 99999 for a tape data set that never expires. This field supports overtype.

REVOKE, PWDREVOKE

This string indicates the maximum number of consecutive invalid password attempts before a userid is revoked on the next invalid attempt (due to a SETROPTS PASSWORD(REVOKE) command). If set to '**No**', userids are never revoked because of invalid password attempts; otherwise, it contains a number in the range 1 to 254.

Notes: a REVOKE value of 5 means a userid is revoked at the *sixth* (not fifth) consecutive invalid password attempt. SPECIAL users are not revoked automatically after too many invalid password attempts; instead, console message ICH301I is issued, and the operator must decide whether or not to revoke the SPECIAL user. This field supports overtype. This field is only present on a RACF system.

RMFLEVEL, RMFLVL

String indicating the software level of RMF. If RMF is inactive, the *Inactive* is returned. If RMF active but zSecure Collect did not have sufficient authorization to collect the release level, the *Active* value is returned.

RVARYSTATUSPWSET

Flag field that indicates if the password for RVARY STATUS has been changed from the default value.

RVARYSWITCHPWSET

Flag field that indicates if the password for RVARY SWITCH has been changed from the default value.

SAUDIT

Flag field that indicates if RACF is logging all commands issued by users having the SPECIAL or group-SPECIAL attribute. It reflects an option set by the SETROPTS SAUDIT command. This field supports overtype.

SECLABELAUDIT

Flag field that indicates if security label auditing is in effect (due to a SETROPTS SECLABELAUDIT command). If set (SECLABELAUDIT=YES), RACF uses the security label's auditing options in addition to the profile's auditing options for all access attempts. If no auditing options are set on the security label's profile, this option has no effect. This field supports overtype.

SECLABELCONTROL

Flag field that indicates if security label control is in effect (due to a SETROPTS SECLABELCONTROL command). If you specify SECLABELCONTROL=YES, only the following users are permitted to use the SECLABEL keyword of RACF commands:

- SPECIAL users (all RACF commands)
- group-SPECIAL users ADDUSER and ALTUSER commands.

If the SECLABELCONTROL keyword is not set, all users with at least READ authority on the SECLABEL class can change profiles with this SECLABEL. This field supports overtype.

SECLEVELAUDIT

This string indicates whether security level auditing is in effect (due to a SETROPTS SECLEVELAUDIT command). If set to '**None**', auditing is not based on security levels; otherwise, it specifies the security level above which all access attempts are audited. This field supports overtype. This field is only present on a RACF system.

SECONDARY_LANGUAGE

This field indicates the RACF secondary language setting as set by SETROPTR LANGUAGE(SECONDARY()).

SECURPASS_SMF_LOG

Flag field that indicates ifProginet's SecurPass logging is active.

SECURPASS_SMF_RECNO

Contains the SMF record type written by the Proginet SecurPass application.

SESSIONINTERVAL, SESSINT

This string specifies the maximum session key interval that can be specified by RDEFINE or RALTER. It is set to a value in the range 1 to 32767 if session keys expire (SETROPTS SESSIONINTERVAL command) to '**None**' if no limit is set (due to a SETROPTS NOSESSIONINTERVAL command). This field supports overtype. This field is only present on a RACF system.

SMF_FLOOD_CONTROL

Indicates if a system has SMF flood detection. If SMF_FLOOD_CONTROL=Y, the SMF_FLOODPOL field contains the SMF flood policy records for SMF flood detection on the specified system.

SMF_FLOODPOL

Contains the SMF flood policy records for a given system if flood detection is active. The policy record for each unique set of SMF record types on the system is represented as a separate entry as shown in the following example.

```
FLOODPOL(TYPE(4,5),INTVLTIME(50),ENDINTVL(100),RECTHRESH(1000),
MAXHIGHINTS(10),ACTION(DROP))
```

FLOODPOL(ffff)

Specifies the flood control filter. The following parameters must be specified in the filter.

TYPE({*aa,bb*}|{*aa,bb:zz*}|{*aa,bb:zz,...*})

Numeric value in the range 0 - 255 that specifies the SMF record types that the filter applies to.

RECTHRESH(*xxxx*)

Numeric value in the range 1- 9999 that specifies the number of records permitted in an interval for a given filter.

INTVLTIME(*ssss*)
Numeric value in the range 1- 9999 that specifies the minimum amount of time that it can take to match the filter, measured in tenths of a second.

ENDINTVL(*ssss*)
Numeric value in the range 1 - 9999 that specifies the amount of time that the filter takes after the `recthreshold` is reached to determine a flood has ended, measured in tenths of a second.

MAXHIGHINTS(*xxxx*)
Numeric value in the range 1 - 9999 that specifies the number of intervals that must occur at or exceeding the flooding rate before action is taken.

ACTION({MSG|DROP})
Specifies the action to be taken when the `MAXHIGHINTS` threshold has been reached for the number of intervals at the specified flooding rate.

Table 556. Action to take when flood detection threshold has been exceeded

Action	Description
MSG	Issue warning message `IFA780A` at the start of the flood. Issue message `IFA781I` when the flooding has stopped.
DROP	Issue message `IFA782A` when the flood starts and also begin dropping records. When flooding ends, issue message `IFA783I` with the number of records dropped. Any attempts to write a record with the `SMFEWTM` or `SMFWTM` macro result in a return code *xx*. For information on the `SEFEWTM` and `SEFWTM` macros, , see the *z/OS MVS System Management Facilities* (SMF) documentation.

SMF17TEMP

Flag field that indicates if information for SMF record type 17 (Scratch Data Set Status) is to be collected for temporary data sets. It reflects the REC parameter in parmlib member SMFPRMxx. If set (SMF17TEMP=YES/REC=ALL), SMF record type 17 is written for both temporary data sets and non-temporary data sets; if not set (SMF17TEMP=NO/REC=PERM), SMF record type 17 is only written for non-temporary data sets.

SMF23INTERVAL, SMFSTATUS

This string indicates the amount of real time between creations of SMF record type 23 (SMF Statistics). It reflects the STATUS parameter in parmlib member SMFPRMxx. The SMF23INTERVAL field has the format 'HH:MM:SS' indicating hours, minutes, and seconds; an empty string indicates no status records are created.

SMFACTIVE

Flag field that indicates if SMF recording is active. It reflects the ACTIVE parameter in parmlib member SMFPRMxx. If set (SMFACTIVE=YES), SMF recording is active.

As an alternative to this field, you can consider using the SMFRECORDING field which also imparts the information whether SMF goes to data set or log stream. However, SMFACTIVE is a flag format field, while SMFRECORDING is a character field

SMFDS_ACTIVE

This field is part of a repeat group describing the SMF recording data sets (all these fields start with SMFDS_xx). Each repeat group entry describes one data

set. Flag field that indicates if the data set is in use (SMFDS_ACTIVE=YES) or not. (This flag describes the active data set at the time the CKFREEZE file was made.)

SMFDS_BLOCKS

This field is part of a repeat group describing the SMF recording data sets (all these fields start with SMFDS_). Each repeat group entry describes one data set. This field describes the number of blocks in the data set.

SMFDS_FILLED

This field is part of a repeat group describing the SMF recording data sets (all these fields start with SMFDS_). Each repeat group entry describes one data set. This field describes the percentage the data set is filled (in use), e.g. 75 if the data set is three-quarter full. (This number describes the data set at the time the CKFREEZE file was made.)

SMFDS_NAME

This field is part of a repeat group describing the SMF recording data sets (all these fields start with SMFDS_). Each repeat group entry describes one data set. This field describes the data set name, for example SYS1.MAN1.

SMFDS_SIZE

This field is part of a repeat group describing the SMF recording data sets (all these fields start with SMFDS_). Each repeat group entry describes one data set. This field describes the size of the data set in kilobytes.

SMFDS_VOL

This field is part of a repeat group describing the SMF recording data sets (all these fields start with SMFDS_). Each repeat group entry describes one data set. This field describes the data set volume.

SMFDUMPABNDRETRY

Flag field that indicates if the SMF dump program attempts to recover if an ABEND occurs. It reflects the DUMPABND parameter in parmlib member SMFPRM*xx*. If SMFDUMPABNDRETRY = YES, the SMF dump program attempts to recover from abends and to continue processing. If SMFDUMPABNDRETRY = *NO*, the SMF dump program terminates on an ABEND event.

SMFJWT

String value that indicates the maximum amount of real time that a job or TSO/E user is permitted to wait continuously before the time limit exit IEFUTL is entered.

This keyword reflects the JWT parameter in parmlib member SMFPRM*xx*. The SMFJWT field has the format 'HH:MM' indicating hours and minutes. If the IEFUTL exit is absent or is not in the exit list for the SMF subsystem, or if the exit does not take any action, a 522 ABEND results.

SMFLASTDSHALT, LASTDSHALT

This flag indicates the system action specified when the last available SMF data set has been filled and no more data sets are available for SMF use. It reflects the LASTDS parameter in parmlib member SMFPRMxx. If set (SMFLASTDSHALT=YES), the system enters a restartable wait state when the last SMF data set is filled; if not set (SMFLASTDSHALT=NO), the system issues a message and continues processing.

SMFLS_ACTIVE

A flag indicating whether the log stream is active or not. Active means SMF records are being directed to it.

SMFLS_BEING_CLEANED

A flag indicating that the system is in the process of removing records from the log stream or removing the log stream, but it still contains data. The field is part of the SMFLS_NAME repeat group.

SMFLS_BUFFERSIZE

The log stream buffer size in kilobytes. Output length is 7. The field is part of the SMFLS_NAME repeat group.

SMFLS_CONNECTED

Indicates that the log stream is connected and records can be written to it. Usually, the log stream status is also active. The exception is during the short period that elapses when an `SET SMF` command is in the process of removing the logstream.

The `SMFLS_CONNECTED` field is part of the `SMFLS_NAME` repeat group.

SMFLS_DEFAULT

A flag indicating whether this is the default SMF log stream or not. The default SMF log stream is the stream where records go that have not been redirected to other streams. The field is part of the SMFLS_NAME repeat group.

SMFLS_NAME

A repeating field of SMF log stream names. The default and maximum useful output length is 26. The field is part of the SMFLS_NAME repeat group that also contains SMFLS_SUMMARY, SMFLS_BUFFERSIZE, SMFLS_WRITETOD, SMFLS_DEFAULT, SMFLS_ACTIVE, SMFLS_BEING_CLEANED, and SMFLS_CONNECTED.

SMFLS_SUMMARY

A repeating field describing SMF log stream recording activity. It shows which SMF record types are being written to this log stream. This field has output length 255, so it is wise to put it as the last field of a line. The field is part of the SMFLS_NAME repeat group.

SMFLS_WRITE_TOD

Date and time stamp of the last write to an SMF log stream. Default output length is 15. The field is part of the SMFLS_NAME repeat group.

SMFMAXDORM, MAXDORM

This string indicates the amount of real time that SMF data can be buffered before being written to a recording data set. It reflects the MAXDORM parameter in parmlib member SMFPRMxx. The SMFMAXDORM field has the format 'MM:SS' indicating minutes and seconds; the value ' **none**' indicates data remains in the buffer until the buffer is full.

SMFNOBUFFSHALT, NOBUFFSHALT

This flag indicates the system action specified when the SMF address space runs out of buffer space. It reflects the NOBUFFS parameter in parmlib member SMFPRMxx. If set (SMFNOBUFFSHALT=YES), the system enters a restartable wait state when the SMF address space runs out of buffer space; no SMF data is lost. If not set (SMFNOBUFFSHALT=NO), the system issues a message and

continue processing; SMF data is lost until buffer storage is available again (in this case, an SMF type 7 record is written when buffer space is next available).

SMFPRM

This string contains the current source used for SMF parameters. It is set to blanks if the default parmlib member SMFPRMxx was used, and it is set to **xx** if the SET SMF command was used to specify a new parmlib member SMFPRM**xx**.

SMFRECORDING

A text field that shows one of the following:

OFF
Indicates that SMF recording is not active.

DATASET
Indicates that SMF recording is active and logging to data sets.

LOGSTRM
Indicates that SMF recording is active and logging to log streams.

This field can be a replacement for the SMFACTIVE setting, but that setting has a flag format. The output length is seven.

SMSLEVEL, SMSLVL

String indicating the software level of SMS and the products licensed in SMS. It has the format `DFSMSv.r.m dss hsm rmm '`; the product identifiers `DSS, HSM` and `RMM` are only returned if the product was licensed.

SYSCLONE

This is a shorthand version of the system name. Maximum length: 2 characters.

SYSLOG_ACTIVE

This flag field indicates that syslog is active.

SYSLOG_CLASS

The name of the JES output class used for the log data sets. A log data set is queued to this class when its limit has been reached, see the SYSLOG_LIMIT field. This value is specified in the `LOGCLS` parameter of parmlib member `IEASYS`*xx*. Logically, this field contains the active setting when the IPL specification is in `IPLPARM_LOGCLS`. However, the `SYSLOG_CLASS` parameter is not dynamic, so the values are the same.

SYSLOG_COMMANDS

This flag field indicates whether the hard copy command log has been set to SYSLOG using a VARY SYSLOG,HARDCPY command. If set, hard copy logging of commands is done to the system log.

SYSLOG_LIMIT

The maximum number of messages permitted for each log data set. When this limit is reached, the log data set is closed and queued to JES, and a new log data set is to be used. This value is specified in the `LOGLMT` parameter of parmlib member `IEASYS`*xx*.Logically, this field contains the active setting, while the IPL specification is in IPLPARM_LOGLMT. However, the `SYSLOG_LIMIT` parameter is not dynamic, so the values are the same.

SYSNAME

The system name as shown in the CVT, originating from the SYSNAME parameter in an IEASYS*xx* PARMLIB member. This value might be the same as the SMF ID retuned in the SYSTEM field.

SYSPERCENT

(not implemented, currently empty)

SYSPLEX

The sysplex name.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system ID. The field length is 8 characters to cater to VM systems.

TAPEDSN

Flag field that indicates if tape data set protection is in effect (due to a SETROPTS TAPEDSN command). If set (TAPEDSN=YES), RACF can protect tape data sets as well as tape volumes. This field supports overtype.

TAPEVOL

Flag field that indicates if the TAPEVOL class is active.

If TAPEVOL is inactive, RACF is not able to guarantee the integrity of tape volumes. Even if TAPEDSN is active, and even if you have a tape management system that assures 44 character data set name integrity (a tape only physically contains the last 17 in its data set header labels), it is still possible to circumvent security because of the fact that there is no protection between data sets on one tape. If you have access to one data set on a tape, you can use a non-APF-authorized program to access information of *all* data sets on the tape. So if you have TAPEVOL inactive, anyone can add an empty data set to that tape (unless it is completely full), and then access the other data sets.

The only way a tape management system can prevent this is either: always checking access to the tape based on the first data set on the tape or: prevent multiple data sets on a tape.

Another protection that is inactive if TAPEVOL is off, is the protection against Bypass Label Processing (BLP). If TAPEVOL is off, no RACHECKS are done by DFP on the FACILITY profile ICHBLP.

TCPIPPROC

This repeated field contains a list of the procedure names for TCP/IP procedures found in the TCP/IP stack.

TCPIPVERS

This repeated field contains a list of the version numbers of all TCP/IP procedures found in the TCP/IP stack.

TEMPDSFORMAT_UNIQUE

Flag field that indicates if the system generates unique data set names for temporary data sets that include `&&label` as the specified data set name, `DSN=&&mydsn` for example. The field value is based on the setting for the `ALLOCxx` `PARMLIB` option `TEMPDSFORMAT(`*`INCLUDELABEL`*`|`*`UNIQUE`*`)`. This field can have the following values.

YES. Indicates that `TEMPDSFORMAT=UNIQUE` is set. The system generates unique names with the following naming pattern:

SYSddddd.Thhmmss.jobname.RA000.Rggxxxxx form. This setting reduces the number of allocation failures caused by the system creating temporary data sets with the same name.

NO. Default value. Indicates that TEMPDSFORMAT= INCLUDELABEL is set. The system generates names in the legacy format which includes the &&dsname label. These names might not be unique.

blank. The TEMPDSFORMAT parameter is only supported for MVS V1R12 or later. For files defined on systems running earlier MVS releases, the field is blank.

TERMINAL

Flag field that indicates if the TERMINAL class is active (due to a SETROPTS CLASSACT(TERMINAL) command). This field is only present on a RACF system.

TERMUACC

This string indicates the default universal access authority associated with undefined terminals (due to a SETROPTS TERMINAL command). It can have the values 'NONE' and 'READ'. This field supports overtype. This field is only present on a RACF system.

TIMEZONE

This field indicates the systems time zone, in the format '**+** HH:MM' or '**-** HH:MM' indicating time relative to GMT. This field can only be used for output, not for SELECT/EXCLUDE processing.

TSOACBPW

This flag field indicates whether the TSO ACB password is present on the system. The password can be set with the ACBPW option in PARMLIB member TSOKEYxx. If a password is specified on the PRTCT parameter of VTAM's APPL definition statement from TSO/VTAM ACBs, then ACBPW must have been specified.

TSOCONFTXT

This field shows whether TSO/VTAM buffers are confidential. The data in the VTAM buffers is overwritten with zeros immediately after the data has been sent to the terminal. This setting also indicates that the buffer content cannot be traced. This option setting can be requested with the CONFTXT option in PARMLIB member TSOKEYxx.

TSOLEVEL, TSOLVL

String indicating the software level of TSO.

TSORECONLIM

Field that indicates the maximum number of minutes that are permitted to pass before reconnection to a TSO session becomes impossible. This setting can be changed from its default of 3 with the RECONLIM parameter in PARMLIB member TSOKEY*xx*.

TSOUSERMAX

This field shows the maximum number of TSO users that can be connected to the system at the same time. This setting can be changed from its default of 40 with the USERMAX parameter in PARMLIB member TSOKEYxx.

TSOUSERS

This field shows the number of TSO users that were actually active on the system during the snapshot.

UNDEFINEDUSER

This string indicates the userid to be used for local jobs that enter the system without a userid; it cannot be set to a userid defined in the RACF database.

The UNDEFINEDUSER can be set by a SETROPTS JES(UNDEFINEDUSER) command; the default is '++++++++'. This field supports overtype.

VMLEVEL, VMLVL

String indicating the software level of VM. This field is empty if zSecure Collect was insufficiently authorized or licensed to collect hypervisor information.

VMSYSTEM

The name of the VM system under which MVS is running. This field is empty if zSecure Collect on z/VM was insufficiently authorized or licensed to collect hypervisor information.

VMUSERID

VM userid of the machine running MVS. It is empty when MVS is not running under VM.

VTAMLEVEL, VTAMLVL

String indicating the software level of VTAM in the format `3.4.1/ESA`.

VTAMNETID, NETID

The network id set by the VTAM start option NETID. This is used in constructed profile names in some classes; for example, the first qualifier of NetView RMTCMD and APPC APPCLU.

WARNING, PWDWARNING

This string indicates the maximum number of days before the expiration of a password, at which RACF is to issue a warning message to a user (due to a `SETROPTS PASSWORD(WARNING)` command). If set to `NO`, no warning is issued. Otherwise, this field contains a number in the range 1-255.

This field is modifiable.

WHENPROGRAM, PROGRAM

This flag indicates whether RACF program control is active (due to a `SETROPTS WHEN(PROGRAM)` command). If the value of `WHENPROGRAM` is *YES*, RACF protection is in effect for access to load modules and Program Access to Data Sets (PADS), independently of whether the PROGRAM class is active or not.

This field is modifiable.

XBMALLRACF

Flag field that indicates ifJES2 is to test jobs to be run with an execution batch monitor for either a valid RACF userid and password or propagated RACF information. If the value of XBMALLRACF is `YES`, all jobs that do not contain the user identification fail.

The option indicated by this flag can be set by a SETROPTS JES(XBMALLRACF) command.

This field is modifiable.

TEMPLATE: RACF Database Templates

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
		•	•	•		

This section documents the fields for NEWLIST TYPE=TEMPLATE. Unless otherwise stated, all fields can be used for SELECT/EXCLUDE processing as well as in the output commands LIST, SORTLIST, DISPLAY and SUMMARY. The NEWLIST TYPE=TEMPLATE displays the templates that describe the fields available in the RACF database as well as custom fields. It generates one entry per field type; a unique key is FIELD ENTITY SEGMENT.

The RACF database templates and custom field definitions from the Dynamic Parse Table are used in the NEWLIST TYPE=RACF to define select/exclude and output fields; the templates and custom fields can also be displayed using the SHOW TEMPLATES command. Only custom fields that do not have the same name as a database template field in the same segment are listed.

Field descriptions

The `TEMPLATE NEWLIST` supports the following fields for reporting.

AIM_ALIAS

Flag field that indicates if the field is an Application Identity Mapping alias name.

ALIAS

If the current field is an alias field, this field contains the name of the original field used whenever this alias name is referenced. If the current field is not an alias field, the value is missing.

COMPLEX

This field identifies the security complex name. The value can come from the ALLOC COMPLEX parameter or default to the security node or sysplex name. The default field length is 8 characters.

If the ALLOC statement for a CKFREEZE data set contains a VERSION= parameter, a blank and the 4-character version are appended to the 8-character complex name. To display the version in the report output, use an output length modifier on the COMPLEX field and specify a value of 13 or greater, or 0. See "Modifying output length" on page 797.

COMMAND_PARM

This field indicates which RACF command parameter can be used to change the field.

COMMAND_PARM_FORMAT

Indicates the name of the output format required for generating a command parameter for a RACF command. If the value is missing, no special formatting is needed to use the field as a command parameter. If the format starts with an underscore then there is no output format available that can directly generate the command parameter value. If the value starts with "_No", the command parameter needs to be formatted as "NO" followed by the keyword, or the keyword with the field formatted according to the rest of the parameter format between parentheses. It can have the following values for the format:

- $Auditlvl, $ACL, $CmdAuth, $CondQt, $Connect, $DOM, $Logdays, $Logtime, $Monitor, $MsgLevl, $MForm, $Quoted, $Yes, $No
- _Add/Del, _CharNone, _CKG, _Echo, _No$CondQt, _No$Quoted, _No$Timeout, _NoChar, _NoKeyword, _NoNum, _Other
- Access, Char, Num, or USdate

DATE3

Flag field that indicates if the field represents a 3-byte date.

DEFAULT

This hexadecimal field contains the default value of the field. This value is only set in a restructured database, and will be missing otherwise. The default value of the field is used if the field is not set in the database.

DESCRIPTION

Contains a Security zSecure description of the use of the field.

EBCDIC_ALIAS

Flag field that indicates if a field that is an Application Identity Mapping alias name contains values in EBCDIC. This field is missing for fields that do not have the AIM_ALIAS flag set.

ENTITY

Contains the name of a RACF profile kind, the entity type. This will be USER, GROUP, DATASET, or GENERAL. When combined with the SEGMENT and FIELD fields, it uniquely identifies an entry in the NEWLIST TYPE=TEMPLATE.

FIELD

Contains the name of a RACF profile field. This name can be used in SELECT, EXCLUDE, LIST, SORTLIST, and SUMMARY commands for the RACF profile report (NEWLIST TYPE=RACF). When combined with the SEGMENT and ENTITY fields, it uniquely identifies an entry in the NEWLIST TYPE=TEMPLATE.

FLAG

Flag field that indicates if RACF considers the database field a RACF flag field, SPECIAL or group-OPERATIONS for example.

FORMAT

This field describes the default Security zSecure output format used for the field.

GROUP

If the current field is part of a repeat group, this field contains the name of the count field that indicates the number of entries in the repeat-group. If the current field is not a repeat group, the value is missing. See also the REPEATED field.

HAS_TEMPLATE

This flag indicates whether a field name is represented in the templates. This flag is ON for all fields except the custom fields from the Dynamic Parse table. The Dynamic Parse table is loaded from the class CFIELD profiles CFDEF segments when IRRDP100 is run.

HAS_DPI

The field name is present as a keyword name in the RACF Dynamic Parse table. For custom fields, the Dynamic Parse table gets loaded from the RACF class CFIELD profile CFDEF segments when IRRDPI00 is run. For non-custom fields in non-base segments, RACF has built-in dynamic parse information such as a maximum input length (MAXLEN), for numeric variables a minimum and/or maximum value (MINVAL or MAXVAL), and for character fields whether they support mixed case (MIXED). The HAS_DPI provides an indication where such information has come from. If HAS_DPI is off and the information is present nonetheless, it comes from the built-in zSecure knowledge base. If HAS_DPI is on and HAS_TEMPLATE is off, you can modify them yourself in the CFDEF segment.

HEADER

Contains the default Security zSecure output header of the field.

HIDDEN

Flag field that indicates if the field is considered to be confidential. Confidential fields are not unloaded by IRRDBU00, and zSecure does not write these fields to an UNLOAD file. If an unloaded database is used for input, the contents of the field is not available.

ID

Contains the sequence id of the RACF field within the segment.

FIRST

Indicates the character set for the first character of a field value. This is derived from the RACF Dynamic Parse Table. The output format is CFSYN by default (shown as selection AN#S). It can also be printed with the $CFSYN format to get strings that RACF uses on the CFDEF segment variable CFFIRST, NONATNUM for example.

HELP

Contains the first line of TSO help text for the keyword from the RACF Dynamic Parse table. The default output length is 64, the maximum length in practice is 255.

LENGTH

The default length of the field on output produced by Security zSecure. If the length is given as Varies, there is no default length, and a ragged column layout may result unless you specify an overriding length value.

MASKED

Flag field that indicates if the value of the field is encrypted in the RACF database, values for passwords for example. zSecure does not write masked fields to an unload file. As a result, this field is not available when an unloaded database is used for input.

MAXLEN

Identifies the maximum length that can be input for the field. It can be either built-in on knowledge or be derived from the RACF Dynamic Parse Table. The default width is 6; the default format is NUM.

This value can only be modified for custom fields. To modify the value, change the CFDEF segment and refresh the Dynamic Parse table. MAXLEN cannot be modified directly on the TYPE=TEMPLATE display.

MAXVALUE

Specifies the maximum value for a numeric variable. The default output length of this field is 10; the default format is NUM.

MINLEN

Specifies the minimum value for a numeric variable. The default output length of this field is 10; the default format is NUM.

MIXED

Flag field that indicates if a field allows case-sensitive input. YES indicates that upper and lower case characters are accepted and preserved. NO indicates that all input is converted to uppercase. The value can come from a template or from dynamic parse information. The default format is $YESNO.

This value can only be modified for custom fields. To modify the value, change the CFDEF segment and refresh the Dynamic Parse table. MIXED cannot be modified directly on the TYPE=TEMPLATE display.

OTHER

Identifies the character set for characters beyond the first. The output format is CFSYN by default (shown as selection AN#S). It can also be printed with the $CFSYN format to get strings that RACF uses on the CFDEF segment variable OTHER, NONATNUM for example.

PAD

Flag field that indicates if RACF pads the field with zeroes on the left if short values are retrieved from the RACF database.

REPEATED

If the current field is part of a repeat group, this flag field is set to YES, otherwise it is set to NO. See also the GROUP field.

SEGMENT

Contains the name of the RACF profile segment the field is a part of. When combined with the FIELD and ENTITY fields, it uniquely identifies an entry in the NEWLIST TYPE=TEMPLATE.

SIZE

Numeric field that indicates the size (in bytes) that the field takes in the RACF database. If the field is of variable length, the value is missing.

SORTED

Flag field that indicates if the field is sorted in the RACF database. Typically, this option is used for repeat group fields that are always referred to in sorted order, CGNGRPNM as opposed to the unsorted values CONGRPNM for example.

STAMP

If the RACF database is an unload, this field displays the local date and time of the unload. If the database is live, it displays current date and time. For a copy of a database, it is displayed as '00:00:00.000000'. It cannot be used for SELECT/EXCLUDE processing.

STATISTIC

Flag field that indicates if the field contains a statistic, REVOKECT and LREFDAT for example. Update of statistics is controlled by the SETROPTS INITSTATS and SETROPTS STATISTICS options.

VLF

Flag field that indicates if changes to the field cause RACF to purge ACEEs from VLF.

TRUSTED: Users that can bypass security

The TRUSTED NEWLIST (NEWLIST TYPE=TRUSTED) provides information about which users can bypass the security for z/OS and your security system and why they have these privileges. Each record in this NEWLIST represents a privilege that allows a specific user on a specific complex to ultimately bypass the security for z/OS and your security system software on the indicated complex and system, which can be the same system or another system. The key for a TRUSTED NEWLIST record consists of the fields that define subject privilege and object sensitivity:

- The Sensitive object key is COMPLEX SYSTEM CLASS RESOURCE VOLSER SENSITIVITY.
- The subject privilege key is USERID USERID_PRIVILEGE USERID_COMPLEX VIA.

Only the USERID_COMPLEX for the default system contains the complete resource analysis. The other complexes are mainly privilege based.

Trusted users must not be defined with a default user ID accessible without authentication by password or other method. Only define the minimum number of trusted users required to represent the total user population. A big site might define between ten and 15 trusted users. You can use the TRUSTED NEWLIST to verify that trusted users are legitimately and correctly defined, and use the records to determine which set of trust relations to eliminate if you want to revoke trust privileges for a user.

Field descriptions

The TRUSTED NEWLIST provides the following fields for reporting.

ACCESS

This field contains the access level of the user on the resource, when operating from the "USERID_COMPLEX" on page 1478. The minimum access level that still would make the user trusted is listed in another field, RISK. (See "RISK" on page 1477.)

The ACCESS field is missing for privileges that do not relate to a resource.

Table 557 list the access levels that can be shown for trust relations established through MVS resources on a RACF system.

Table 557. TRUSTED access levels granted through MVS resources

Access	Explanation
ALTER	ALTER access
ALTER-M	Authority to alter some fields in his own user profile
ALTER-O	Authority to alter caused by a group-operations attribute
ALTER-P	Authority to alter a discrete profile (allowing you to issue PERMIT)
CONTROL	CONTROL access
CKGOWNR	Authority to access/change information using CKGRACF through the CKG.SCP scope profiles. The real access depends on CKG.CMD profile access. This can only be more access than standard RACF, not less

Table 557. TRUSTED access levels granted through MVS resources (continued)

Access	Explanation
CREATE	Authority to create a more specific profile, or CREATE authority in a group
EXECUTE	EXECUTE access
NONE	No access
OWNER	Authority through ownership
QUALOWN	Authority based on the qualifier of a data set profile. If the data set HLQ is an userid, this userid has QUALOWN authority. Otherwise, if the data set HLQ is a groupid, any user with group-special
READ	READ access
UPDATE	UPDATE access

Table 558 list the access levels that can be shown for trust relations established through UNIX resources.

Table 558. TRUSTED access levels granted through UNIX resources

Access	Explanation
EXECUTE	`--x` access
NONE	`---` access
READ-NX	`r--` access
READ	`r-x` access
UPD-NX	`rw-` access
UPDATE	`rwx` access
WRIT-NX	`-w-` access
WRITE	`-wx` access

AUDITPRIORITY

Contains the audit priority that measures the risk the privilege poses. The value is 40 or higher if the privilege is a major exposure. For example, the user ID value represents some default user anybody can use.

AUDITCONCERN

Explains how the privilege can be used to obtain the highest system authorization. This field might also contain additional information to explain high audit priorities.

Table 559. TRUSTED: Audit concerns

Audit priority	Audit concern
2	Can modify zFS data set while unmounted, might be mounted SETUID later.
5	Can modify SETUID zFS data set while unmounted, can gain UID(0).

CLASS

Contains the resource class of the resource that the user has access to. For privileges, it identifies the type of object or subject where the privilege or security attribute resides.

COLLECT_DATETIME

Returns the time stamp that indicates when the CKFREEZE file was created. If no CKFREEZE file is in use on a live system, the date and time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

Contains the name of the security complex the SYSTEM belongs to, and hence the sensitive resource. The combination of the COMPLEX SYSTEM fields identifies the system that the user can manipulate. This can be specified by the COMPLEX= keyword on an explicit ALLOC statement, or it defaults to a system name.

RACF_CLASS

The class name of the RACF_PROFILE. RACF_CLASS can refer to the associated grouping class, while CLASS refers to a member profile class. The RACF_CLASS protects the RACF profile key when it is accessed from the security complex of USERID_COMPLEX. See "USERID_COMPLEX" on page 1478.

RACF_PROFILE

The RACF profile key in the class RACF_CLASS that protects the profile key when it is accessed from the security complex of USERID_COMPLEX. See "USERID_COMPLEX" on page 1478.

RESOURCE

Contains the resource name in the domain of the SAF resource class listed in CLASS. The maximum length of the field is 255 bytes. This field is missing for privileges that are not associated with a specific resource.

RESOURCE_LOCATION

Identifies the resource name environment. This field is repeat group field. The default and maximum length is 35 characters. An example value is IPO1.CICS.CICSTS41.DATASET. The format is as follows:

system.subsy-type.subsys-identification.restype

RISK

Contains the minimum access level that still makes the user trusted. The actual access granted to the user is found in the ACCESS field. (See "ACCESS" on page 1475.)

The RISK field is missing for user privileges.

SENSITIVITY

Contains the type of sensitivity the resource has on the system identified by the COMPLEX SYSTEM fields. In addition the following sensitivity types can be listed:

Table 560. TRUSTED: Additional sensitivity types

Sensitivity	Meaning
CICS Loadlb	CICS program library
CICS CSD	CICS resource definition data set
CICS Parms	CICS parameter library
CICS ACF2pr	ACF2/CICS parameter library
DB2 BootSDS	DB2 Bootstrap data set (BSDS)

Table 560. TRUSTED: Additional sensitivity types (continued)

Sensitivity	Meaning
Dflt ID map	This user is mapped to by the default distributed identity filter (* for both registry and filter).
ID mapping	This user is mapped to by a distributed identity filter.
IMS PROCLIB	IMS program library
Privilege	The user has a special privilege or security attribute (not through SAF on all ESMs). For RACF these include OPERATIONS, SPECIAL. For HSM these include HSM CNTL, HSM USER.
Resource	The user has SAF access on a sensitive general resource (classes include DASDVOL, FACILITY, FIELD, HFSSEC, LOGSTRM, PRIVCTL, TSOAUTH, UNIXPRIV, VMMDISK, VMSEGMT).
zFS	zFS data set

In case of multiple sensitivities for a single data set, only the prime sensitivity or sensitivities are represented. For instance, a data set can be a MSTR parmlib, a JES2 parmlib, an STC proclib and a JOB proclib all at the same time. In this case it will be shown as a JES2 parmlib, because that data set may contain human readable passwords.

SYSTEM

Contains the name of the target system where the sensitive resource resides. That is, the system that can be manipulated or attacked by the user.

USERID

Contains the user ID value that has access to the privilege described in the record.

USERID_COMPLEX

Contains the name of the security complex where the `USERID` is defined. That is, the complex from which the user can access the resource. This value can be specified by the `COMPLEX=` keyword on an explicit `ALLOC` statement, or it defaults to a system name.

USERID_PRIVILEGE

Contains the name of the user privilege, security attribute, or sensitive operating system function the user has access to. This value is a privilege on the complex where the user is defined, `USERID_COMPLEX`. The maximum length of the field is 9 bytes. The field can contain any of the following values

- *CLASS*: *A*, *B*, *C*, *D*, *E*, *F*
- *AUTH*:*ClassAuth*, *ConnAuth*, and *DUMPAUTH*
- *GROUP*: *GroupOper*, *GroupSpec*
- *HSM*: *HSM USER*, and *HSM CNTL*
- *JOBFROM*
- *MAINT*
- Mapped ID
- *MUSASS*
- *NON-CNCL*
- *Operations*

- *Owner*
- *Permit*: *PermitGrp*, *PermitUsr*, *Permit Prefix*
- *READALL*
- *Rule*: *Rsrc rule*, *No Protect*, *NoRule*, and *Rule*
- SECURITY
- *Special*
- *Superuser*
- *TAPE-BLP*
- *UACC*
- *Unix*: *UnixGroup*, *UnixOther*, *UnixOwner*,, and *UnixUser*
- *Warning*

VIA

Contains the group or userid that provided access. The group is returned if access is given through a group. Group access is indicated when the USERID_PRIVILEGE field contains any of the following values: *PermitGrp*, *GroupSpec*, *GroupOper*, or *UnixGroup* in field. If access was given through class authorization, this field contains the userid.

VOLSER, VOLUME

Contains a volume serial further identifying the resource name in field RESOURCE. This field is missing for privileges not relating to a resource, and for resources that are not associated with a specific volume serial.

TYPE: Newlist type definitions

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The TYPE NEWLIST (NEWLIST TYPE=TYPE) lists the NEWLIST types supported by the product and provides the original English and default translated properties for each type.

The key for records in TYPE NEWLIST is NEWLIST_TYPE. An alternate key is NEWLIST_TAG.

Field descriptions

Table 561 list the fields available in the TYPE NEWLIST. Descriptions for each field follow the table.

Table 561. NEWLIST TYPE=type parameter descriptions

Field	Column Header	Length
ABBREV2	T2	2
DETAILHELPPANEL	Det help pnl	8
HELPPANEL	Help pnl	8
NEWLIST_TAG	Tag	3
NEWLIST_TYPE	Type	24
TOPTITLE	Toptitle	64

Table 561. NEWLIST TYPE=type parameter descriptions (continued)

Field	Column Header	Length
TOPTITLE_ORIG	Original toptitle	64

ABBREV2
A unique two character representation of the NEWLIST type. It is used in some default panel names and can be used in generation of ddnames. This number can change without warning and is not a programming interface.

DETAILHELPPANEL
The default help panel name used for a detail display of this type.

HELPPANEL
The default help panel name used for a summary or overview level display of this type.

NEWLIST_TAG
An internal number for the NEWLIST type. This number can change without warning and is not a programming interface.

NEWLIST_TYPE
The NEWLIST type in character format.

TOPTITLE
The default top title used for translated output of this NEWLIST type.

TOPTITLE_ORIG
The original English default top title for output of this NEWLIST type.

UNIX: UNIX System Services File System

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•			•	•	•	•

The UNIX NEWLIST (NEWLIST TYPE=UNIX) describes the unified file system used by the z/OS UNIX System Services on each system. To use this type, you must have one or more CKFREEZE files that provide information about the data set content of the file system and the current mount points. For a summary of the mount points, see "MOUNT: UNIX Mount Points" on page 1104. This NEWLIST type only provides information about the UNIX files system data sets that are mounted.

- Each record in this NEWLIST represents an (effective) directory entry.
- A record is uniquely identified by the fields SYSTEM, COMPLEX, DEV and REL_PATHNAME
  - SYSTEM and COMPLEX define the system being considered. These fields are also an alternate key.
  - The DEV number represents a mount point with the following characteristics FS_SYSTEM, FS_COMPLEX, FS_DSN, FS_VOLSER, FS_SERIAL that determine the relation between REL_PATHNAME and ABS_PATHNAME and thus the file system mounted there.
  - REL_PATHNAME indicates the directory entry within the file system.
- The fields SYSTEM, COMPLEX and ABS_PATHNAME are an alternate key.
- Within a file system, several directory entries can describe the same file (multiple REL_PATHNAMEs, one INODE). In UNIX there is no such thing as the *real name* of a file. The effective attributes take the settings along the separate paths to the file into account.

Field descriptions

The UNIX NEWLIST provides the following fields for reporting.

ABS_PATHNAME

The absolute path name for this record.

ATTR

The file's attributes (including access modes), by default printed as 'rwxrw-r--'. In this example, the owner has read, write and execute access, the file's group read and write access, others have only read access. The setuid, setgid and sticky bits are also taken into account in the consecutive 'x' positions, resulting into 's' or 't' (when the execute bit itself is off: 'S' or 'T'). See “Formatting UNIX file type, attribute, and audit flag fields” on page 823 for alternate formats OCTAL and $CHMOD, and extended syntax selection. See also “TYPE” on page 1489 and “EXTATTR” on page 1486.

The ATTR field shows the effective attributes, which are a combination of the physical attributes set for the file itself with the mount attributes of the file system it is in and the effective attributes of the directories in the path to the file. If the file system is mounted NOSETUID or NOSECURITY the setuid and setgid attributes are disabled. NOSECURITY disables the sticky bit for directories as well, and access is allowed without the read, write or execute attributes as well. If the file system is mounted READ-only (instead of RDWR), write access is effectively disabled. The attributes physically stored in the file system data set can be found in “PHYSICAL_ATTR” on page 1489 See also “unxhfse” on page 1487 and “FS_SERIAL, HFS_SERIAL” on page 1487.

AUDITCONCERN, CONCERN

Indicates the reason for the audit priority. You should not make use of the exact value of this field. The value can contain one or more audit concerns separated by commas. The following audit concerns have currently been defined:

Table 562. Audit concern descriptions

Audit concern	Description
executable file bypasses file security (setuid 0)	This executable file runs with superuser authority even when executed by a normal user. There are normal utilities that need this authority. These files should be monitored closely, their origin should be known and changes in contents and attributes should be audited.
executable file masquerades as another user and group (setuid/setgid)	This executable file does not run with the current user's uid and gid, but with another uid and gid.
executable file masquerades as another user (setuid)	This executable file does not run with the current user's uid, but with another uid.
executable file masquerades as belonging to a different group (setgid)	This executable file does not run with the current user's gid, but with another gid.
executable file runs program-controlled (extattr +p)	This executable file must run in a clean, controlled environment. If it does, it may have additional authorities (like daemon, server).

Table 562. Audit concern descriptions (continued)

Audit concern	Description
executable file runs APF-authorized (extattr +a)	This executable file runs as if loaded from an APF-authorized library. For example, if this program is exec()ed at the job step level and the program is linked with the AC=1 attribute, the program will be executed as APF-authorized.
special file is world writable	This special file (/etc/rc, /etc/profile, or /etc/automount.master) can be overwritten by anyone with access to z/OS UNIX System Services. Files reported with this concern need to be investigated especially, because they are important configuration files. For symbolic links (including external links) this condition is not reported, because the attribute setting is standard and typically ignored (the authorizations of the link's target are checked instead).
file is world writable	This file can be overwritten by anyone with access to z/OS UNIX System Services. This concern needs to be investigated especially for configuration files like files in the /etc directory. For symbolic links (including external links) this condition is not reported, because the attribute setting is standard and typically ignored (the authorizations of the link's target are checked instead).
special directory is world writeable but existing entries are protected (sticky bit)	When the Sticky bit is set on a directory, only the owner of a file in that directory (or a superuser) is allowed to delete or rename that file. However, anyone with access to z/OS UNIX System Services is allowed to create a new file in this special directory (the root directory or /etc). For some files their existence is enough to alter security decisions, e.g. ftp or cron allow or deny files. Other files are executed automatically if they exist, e.g. a file .profile in the home of a user, and this file will be run under this user's privileges. Note that root is the default for a user's home directory.
directory is world writeable but existing entries are protected (sticky bit)	When the Sticky bit is set on a directory, only the owner of a file in that directory (or a superuser) is allowed to delete or rename that file. However, anyone with access to z/OS UNIX System Services is allowed to create a new file in this directory.
home directory is world writeable but existing entries are protected (sticky bit)	When the Sticky bit is set on a directory, only the owner of a file in that directory (or a superuser) is allowed to delete or rename that file. However, anyone with access to z/OS UNIX System Services is allowed to create a new file in this directory. In addition, it the home directory of the user specified by the HOME_OF field.

Table 562. Audit concern descriptions (continued)

Audit concern	Description
special directory is world writable	This special directory (the root directory or /etc) allows anyone with access to z/OS UNIX System Services to change entries in it. This needs to be investigated especially because they contain configuration files. Write access on the directory allows anyone to rename a file. This could make it possible to switch configuration files. As an example it would be possible to swap a current /etc/ftp.data (maybe with tighter security) with another copy that was saved by an administrator. The copy might enable anonymous ftp, while this is not allowed by the current version of /etc/ftp.data. If the directory is also world readable it would ease finding a suitable "other" configuration file.
directory is world writable	This directory allows anyone with access to z/OS UNIX System Services to change entries in this directory. This concern needs to be investigated especially for directories that contain configuration files. Write access on the directory allows anyone to rename a file.
home directory is world writable	This directory allows anyone with access to z/OS UNIX System Services to change entries in this directory. In addition, it the home directory of the user specified by the HOME_OF field.
/tmp is world writable and existing entries are not protected (no sticky bit)	The /tmp directory allows anyone with access to z/OS UNIX System Services to change entries in this directory. Write access on the directory allows anyone to rename a file. It is recommended that this directory has the sticky bit set.
.profile in user's home directory is world writable	This file can be overwritten by anyone with access to z/OS UNIX System Services. In addition, this is a special file that is automatically executed when a user to whom it applies logs on to z/OS UNIX System Services, thereby forming a major risk where Trojan horse attacks are concerned. Check the HOME_OF field for the directory where the file resides to see which user it applies.
Emacs initialization file in user's home directory is world writable	This file can be overwritten by anyone with access to z/OS UNIX System Services. In addition, this is a special file that is automatically executed when a user to whom it applies starts the Emacs editor, thereby forming a major risk where Trojan horse attacks are concerned. Check the HOME_OF field for the directory where the file resides to see which user it applies.

Table 562. Audit concern descriptions (continued)

Audit concern	Description
`sh_history in user's home directory is world writable`	This file can be overwritten by anyone with access to z/OS UNIX System Services. In addition, this is a special file containing a history of previously entered shell commands to be used for retrieval and re-execution; commands in it may therefore easily be executed by a user to whom it applies; thereby forming a risk where Trojan horse attacks are concerned. Check the HOME_OF field for the directory where the file resides to see which user it applies.
`Seclabel does not conform to the recommendation of` *`seclabel`*	A specific security label is recommended for this file or directory, as documented in the book "Planning for Multilevel Security and the Common Criteria", chapter "Establishing Multilevel Security".
`cron not disabled. Security labels can be bypassed`	cron is a clock daemon that runs commands at specified dates and times. It does not check security labels, and should be disabled for general use in a multilevel-secure environment. This can be done by giving it SYSHIGH, or a unique security label that is not dominated by a general user security label.
`Automount managed directory does not conform to the recommendation of SYSMULTI`	All automount managed directories should have the SYSMULTI security label assigned to ensure the availability of mounted data, regardless of security label.
`Security label substitution is not performed`	Security label substitution for a symlink with a linktarget of $SYSSECA or $SYSSECR will only be done when the SECLABEL class is active, and the system runs z/OS 1.5 or later.

Any of the preceding audit concerns can be suffixed with `but path-protected`. This indicates that the file security information as kept with the inode allows what the audit concern states, but the path to the inode described in this record does not. There might be different paths (hardlinks) to the same inode that do not prevent the audit concern condition from being exploited.

AUDITFLAGS

This 3-character field contains the effective audit flags for read, write and execute attempts (in that order). Each can be 's' (success audit), 'f' (failure audit), 'a' (all access) or '-' (no auditing). Auditing occurs effectively when either the auditor or the user has requested it. See “AUDITFLAGS_AUDITOR” and “AUDITFLAGS_USER” on page 1485. See “Formatting UNIX file type, attribute, and audit flag fields” on page 823 for alternate format $CHAUDIT and the extended syntax supported for SELECT/EXCLUDE processing.

AUDITFLAGS_AUDITOR

This 3-character field contains the auditor-specified audit flags for read, write and execute attempts (in that order). Each can be 's' (success audit), 'f' (failure audit), 'a' (all access) or '-' (no auditing). See 1484 and “AUDITFLAGS_USER” on page 1485. See “Formatting UNIX file type, attribute, and audit flag fields” on page 823

on page 823 for alternate format $CHAUDIT and the extended syntax supported for SELECT/EXCLUDE processing.

AUDITFLAGS_USER

This 3-character field contains the user-requested audit flags for read, write and execute attempts (in that order). Each can be 's' (success audit), 'f' (failure audit), 'a' (all access) or '-' (no auditing). See 1484 and "AUDITFLAGS_AUDITOR" on page 1484. See "Formatting UNIX file type, attribute, and audit flag fields" on page 823 for alternate format $CHAUDIT and the extended syntax supported for SELECT/EXCLUDE processing.

AUDITID

The file's audit id. It is currently only available for files in an HFS. When selecting on this field, you should use the exact hexadecimal value.

```
select auditid='01E2D4F3F0F0F933EA1C000002300000'x
```

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 563. UNIX NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

This field contains the name of the (viewpoint) security complex. This can by specified via the COMPLEX= keyword on an explicit ALLOC statement, or it may default to a system name.

DEPTH

This field contains the directory level for the file.

DEV

This field contains the device number, which is an identification of the file system data set in which the file described by this record resides, via the list of mounted file systems for this system. DEV and INODE uniquely identify a physical file within a unified file system; if LINK_COUNT is greater than one, it has multiple directory entries ('hard links'). See also INODE and FS_DSN.

DIRECTORY_DEFAULT_ACL

This flag field is only present for a directory. It indicates if the directory has a directory default access list or not. See “UNIX_DEFAULT_ACL” on page 1492 for the content of the access list.

DIRNAME

The pathname without the last qualifier, for example, the name of the directory this entry is in. Note that a mount point is represented both as a directory in its parent file system and as '.' within the file system mounted there. For the latter entry DIRNAME will equal ABS_PATHNAME.

EXTATTR

The extended attributes, e.g. 'a---' for APF-authorized, '-p--' for program controlled, '--s-' to indicate _BPX_SHAREAS (OMVS share address space setting) is honored, '---l' to indicate library sharing is allowed. Note that 's' is set by default, if a file does not have the attribute it will always be started in its own address space. See “Formatting UNIX file type, attribute, and audit flag fields” on page 823 for the alternate format $EXTATTR and the extended syntax supported for SELECT/EXCLUDE processing.

The EXTATTR fields shows the effective attributes, which are a combination of the physical extended attributes set for the file itself with the mount attributes of the file system it is in. If the file system is mounted NOSETUID or NOSECURITY the APF and program control attributes are disabled. The extended attributes physically stored in the file system data set can be found in “PHYSICAL_ATTR” on page 1489. See also “unxhfse” on page 1487 and “FS_SERIAL, HFS_SERIAL” on page 1487.

EXTENDED_ACL

Flag field that indicates whether the file or directory has an extended access ACL (access list). See “UNIX_ACL” on page 1489 for the actual access list content.

EXTERNAL_LINK

Flag field that indicates whether the entry is a link to an MVS data set or member. The target of the link can be found in “LINK_TARGET” on page 1488.

FILE_DEFAULT_ACL

Flag field indicates if the directory has a file default access list or not. This value is only present for a directory. See “UNIX_FDEFAULT_ACL” on page 1492 for the content of the access list.

FILENAME

The last qualifier of REL_PATHNAME. Note that a mount point is represented both as a directory in its parent file system and as '.' within the file system mounted there. The latter entry shows the FILENAME as '.'.

FS_COMPLEX, HFS_COMPLEX

Contains the name of the security complex of which the system that owns the file system data set indicated by DEV is a part. See also “FS_SYSTEM, HFS_SYSTEM” on page 1487.

FS_DSN, HFS_DSN

The MVS data set name of the file system associated with DEV. Note it may not be directly accessible from SYSTEM. See “FS_SYSTEM, HFS_SYSTEM” on page 1487.

FS_MOUNTPOINT, HFS_MOUNTPOINT

Absolute pathname for the mount point of the file system associated with DEV.

FS_RDWR, HFS_RDWR

Flag field that indicates if the file system associated with DEV is mounted in read/write mode.

FS_SECURITY, HFS_SECURITY

Flag field that indicates if the file system associated with DEV is mounted with the SECURITY option, for example, whether security checks are performed. Note that if this is not the case, setuid, setgid, APF, and program control bits are ignored, and for directories the sticky bit as well.

FS_SERIAL, HFS_SERIAL

Describes the DASD unit's volume serial number and device id for the file system's data set. This field may not be filled in if the CKFREEZEs allocated do not contain a detailed description of the FS_SYSTEM as well as SYSTEM (as they may differ). This field can be used to disambiguate between DASD volumes with the same FS_VOLSER. See also "BOX_SERIAL field for DASDVOL report" on page 1014 for further details.

FS_SETUID, HFS_SETUID

Flag field that indicates if the file system associated with DEV is mounted with the SETUID option, for example, whether setuid, setgid, APF, and program control bits are to be honored. The file system must also be mounted with the SECURITY option for these bits to be honored.

FS_SYSTEM, HFS_SYSTEM

Contains the name of the system that owns the file system data set indicated by DEV. (It is possible to share a unified file system within a sysplex; the actual file system data set can be managed by one system, while all systems have access to it, even if they do not share the DASD.)

FS_VOLSER, FS_VOLUME, HFS_VOLSER

The (first) volume serial of the file system associated with DEV. This field may not be filled in if the CKFREEZEs allocated do not contain a detailed description of the FS_SYSTEM as well as SYSTEM (as they may differ).

GID

The group for the file (GID). See also "GROUP."

GROUP

The group for the file , shown as a RACF identity if one is available (reverse translation). If several reverse translations are possible, the alphabetically first is shown. See also "GID," "OWNER" on page 1488 and "UID" on page 1489.

HFS_COMPLEX

This field is an alias for the FS_COMPLEX field. See "FS_COMPLEX, HFS_COMPLEX" on page 1486 for details.

HFS_DSN

This field is an alias for the FS_DSN field. See 1486 for details.

HFS_MOUNTPOINT

This field is an alias for the FS_MOUNTPOINT field. See "FS_MOUNTPOINT, HFS_MOUNTPOINT" on page 1486 for details.

HFS_RDWR

This field is an alias for the FS_RDWR field. See “FS_RDWR, HFS_RDWR” on page 1487 for details.

HFS_SECURITY

This field is an alias for the FS_SECURITY field. See “unxhfse” on page 1487 for details.

HFS_SERIAL

This field is an alias for the FS_SERIAL field. See “FS_SERIAL, HFS_SERIAL” on page 1487 for details.

HFS_SETUID

This field is an alias for the FS_SETUID field. See “FS_SETUID, HFS_SETUID” on page 1487 for details.

HFS_SYSTEM

This field is an alias for the FS_SYSTEM field. See “FS_SYSTEM, HFS_SYSTEM” on page 1487 for details.

HFS_VOLSER

This field is an alias for the FS_VOLSER field. See “FS_VOLSER, FS_VOLUME, HFS_VOLSER” on page 1487 for details.

HOME_OF

This repeated field can only be filled in for a directory. It lists the RACF users for whom this directory is their home directory.

INODE

Contains an inode number, which uniquely identifies a physical file within a physical file system. Together with DEV this identifies a single file in a unified file system. A UNIX file generally does not have a unique filename; instead, there may be multiple path names (known as 'hard links') that point to the same INODE. LINK_COUNT contains the number of hard links to the file. For each pathname a separate record with the same DEV and INODE will be produced (for each unified file system view, for example, per system/complex). Permissions and attributes are associated with the INODE, so they are the same for all hard links to it.

LINK_COUNT

The number of hard links to the file described by the current entry. A UNIX file generally does not have a unique filename; instead, there may be multiple path names (known as 'hard links') that point to the same INODE. (If LINK_COUNT is equal to one, there is only one hard link, so that pathname could be considered to be the name of the file.) Symbolic links are not included in this count.

LINK_TARGET

For a symbolic link, this field contains the pathname linked to. A symbolic link is a file which redirects one pathname to another (by name). It does not specify an inode, and it can point to another physical file system. If the file is deleted, the symlink is kept and may again become active when a file of the indicated name is created again.

For an external link, this field contains the MVS data set or member linked to. In the case of a member name, the current MVS search order for the module at execute time applies.

OWNER

The owner of the file, shown as a RACF identity if one is available (reverse translation); if several reverse translations are possible, the alphabetically first is shown. See also "UID," "GROUP" on page 1487 and "GID" on page 1487.

PHYSICAL_ATTR

The attributes for the file as physically stored in the file system data set; the effective attributes can be found in ATTR. See "ATTR" on page 1481.

PHYSICAL_EXTATTR

The extended attributes for the file as physically stored in the file system data set; the effective attributes can be found in EXTATTR. See "EXTATTR" on page 1486.

REL_PATHNAME

The pathname for the record within the file system's data set it is contained in, for example, relative to the mount point associated with this DEV. If you unmount a file system from one mount point and remount it elsewhere, the absolute pathname will have changed but this field will have remained constant.

SECLABEL

The security label of the file. If an assumed security label is in effect, this field contains the READONLY_SECLABEL. See "READONLY_SECLABEL" on page 1106.

SYMBOLIC_LINK, SYMLINK

Flag field that indicates whether the entry is a symbolic link. The target of the link is contained in LINK_TARGET.

SYSPLEX

The name of the sysplex the SYSTEM is a part of (if applicable).

SYSTEM

The name of the (viewpoint) system. For MVS systems, this is the SMF system id; the field length is 8 characters by default for compatibility with other NEWLISTs.

TYPE

The file type. The type is represented by one of the following values: - (regular file), *d* (directory), *ll* (symbolic link), *e* (external link),*p* (pipe/ FIFO),*s* (socket), *c* (character special file), or *b* (block special file). See also "ATTR" on page 1481.

UID

The file owner (a UID). See also "OWNER" on page 1488.

UNIX_ACL

Repeated field that can be used to display the access granted on a UNIX directory entry.

Note: See "EXTENDED_ACL" on page 1486to test for the existence of actual ACL entries.

This field is also completed in correspondence with the ATTR or PHYSICAL_ATTR settings.

The access list content for each directory entry includes the following fields: **User**, access description (**TOrwx**), **ACL id** and **UID/GID**. See "UNIX directory entry access list content - field descriptions." The content included in each entry depends on the access list format setting: `NORMAL`, `EXPLODED`, `RESOLVED` or `EFFECTIVE`. For descriptions of the formats, see "Access list format settings for UNIX" on page 1492.

UNIX directory entry access list content - field descriptions

The contents of the `UNIX_ACL`, `DEFAULT_ACL`, or `UNIX_FDEFAULT_ACL` fields is displayed in tabular format with the following column headings.

`User`

The **User** column shows the RACF user that is allowed access. If a group is not expanded to its containing users, this column shows -**group**- instead. If a UID or GID occurs in the access list, but has no related RACF identity, -**undef**- might be shown in this column. For the global access setting (the 'other' bits on the ACL), this column will show - **any** -.

`Access description (TOrwx)`

The access description field (**TOrwx**) contains the type of ACL in the **T** column, the origin of the entry in the **O** column, and the read, write and execute bits in the **rwx** columns.

- Table 564 lists the possible ACL types (**T**):

Table 564. Access description field - ACL Types

Value	ACL Type
blank	UNIX_ACL
d	UNIX_DEFAULT_ACL
a or **f**	UNIX_FDEFAULT_ACL

- The **O** column displays the origin attribute for the entry. Table 565 shows the possible values.

Table 565. Origin attribute types

Attribute	Description
u	the file owner
g	the owning group
o	other users
+	ACL entries
a	RACF auditor access

The origin is important because of the precedence rules for access determination. The file owner is checked first, followed by user ACL entries. If none of the values match the uid of the requestor, then the owning group and group ACL entries are checked. The group entries are considered equal in rank, and if any entry grants the requested access, it is granted. If file owner, user, or group values do not match, the *other* value is checked. In this case, some additional rules apply: If a user has the RACF RESTRICTED attribute and a protected value for the resource name RESTRICTED.FILESYS.ACCESS in the UNIXPRIV class (UNIXPRIV must be active and RACLISTed), then the *other* bits are not used unless the restricted user has at least READ access.

Users with the RACF AUDITOR attribute have read and execute access to all directories (that is, they can view the file system). Superusers (root users) generally have access too, but this access is not reflected in these fields.

Note: ACL entries are only checked if class FSSEC is active.

- The value of **rwx** (read, write and execute bits) can show either **r**, **w** and **x** for read, write and execute allowed, respectively, or **-** if the corresponding access is not allowed.

ACL id

The **ACL id** column shows the RACF identity for the uid or gid that is actually on the access list. If the uid or gid is shared, entries for all related RACF entries might be present. Alternatively, the **ACL id** column shows `-other-` for the other bits entry. If the uid or gid has no RACF identity, the **ACL id** value (see Table 566) indicates whether the access is for a uid or for a gid.

Table 566. ACL id values for uids or gids without a RACF identity

Value	Meaning
`-owner-`	Access is granted based on the owning uid.
`-group-`	Access is granted based on the owning gid.
`-ACLuid-`	Access is granted based on a uid on the ACL.
`-ACLgid-`	Access is granted based on a gid on the ACL.
`-audit-`	A RACF user is granted read and execute access to a directory because of the system-wide AUDITOR attribute rather than an ACL entry.
`-more-`	If the access list format setting is ACL RESOLVE or ACL EFFECTIVE, **`-more-`** value indicates that access is granted based on a composite of other entries, and therefore not related to a single ACL entry.

UID/GID

The **UID/GID** column shows the uid or gid that grants the access, or an indication why none applies.

Table 567. UID/GID values

Value	Description
n	A number (*n*) indicates the uid or gid depending on the value in the User and ACL id columns. The number indicates a uid if the **User** and **ACL id** columns show the same RACF user, or if the **ACL id** column shows `-owner-` or `-ACLuid-`. The number indicates a gid if the **ACL id** column shows `--group-`, `-ACLgid-`, or a RACF identity (user) different from the one (group) in the **ACL id** column.
n/a	This value indicates that no uid or gid applies because the entry is the global access setting (**ACL id** = `-other-`), a composite entry (**ACL id** = `-more-`, or a RACF user allowed access because of the AUDITOR attribute (**ACL id** = `-audit`).
no uid **no gid**	If the format setting is ACL EXPLODE, the UID/GID be shown that a RACF user would have had access as an AUDITOR but does not have it, because there is no uid or gid associated with the user (either direct, or through BPX.DEFAULT.USER); in that case this column may contain **no uid** or **no gid**.

UNIX_DEFAULT_ACL

Repeated field for displaying the default access granted to directories created within this directory. For details on the access list content included and access list format settings, see “UNIX_ACL” on page 1489. See “DIRECTORY_DEFAULT_ACL” on page 1485 to test for existence of the directory default ACL.

UNIX_FDEFAULT_ACL

Repeated field that can be used to display the default access granted to files created within this directory. For details on the access list content included and access list format settings, see “UNIX_ACL” on page 1489. See “FILE_DEFAULT_ACL” on page 1486 to test for the existence of the file default access list.

Access list format settings for UNIX

The access information shown for each UNIX directory entry depends on the access list format setting. For interactive displays, you can control the format using the ACL command. See “Access list display modes - reference material” on page 30. For generated output, you can specify the format using an output modifier. See the examples in “Formatting UNIX file type, attribute, and audit flag fields” on page 823. The following format settings are available:

ACL NORMAL

For entries with access type UNIX_ACL. the entry includes the following information, depending on the origin:

- If the origin is an owning uid, the uid is used to create an entry for each matching RACF user. If no RACF identity is available, an entry is created with **User -undef-** and **ACL id -owner-**.
- If the origin is an owning gid, the gid is used to create a **-group-** entry for each matching RACF group. If no RACF identity is available, an entry is created with **ACL id -group-**.
- If the origin is other, an entry is added with **ACL id - other -**.

Entries for the access ACL of directories and the file directory default ACL include the following information:

- The uids on the appropriate ACL are processed and used to create an entry for each matching RACF user. If no RACF identity is available, an entry is created with **User** = **-undef-** and **ACL id** = **-owner-**.
- The gids on the appropriate ACL are processed and used to create a **-group-** entry for each matching RACF group. If no RACF identity is available, an entry is created with **ACL id -ACL gid-**. The access bits used are taken from PHYSICAL_ATTR.

ACL EXPLODE

This format setting functions much like ACL NORMAL with the following differences:

- Instead of adding a group entry, entries are added for all users connected to the group.
- If the group is empty, the group entry is retained.
- For the access ACL of directories and the directory default ACL, entries for read/execute access due to the RACF AUDITOR attribute are added as well.

ACL RESOLVE

This format setting functions much like ACL EXPLODE with the following differences:

- Empty groups and -undef- entries are omitted.
- Multiple entries for the same user are resolved. That is, the file owner takes precedence over an ACL entry for the same user.
- Any true user entry takes precedence over one that would be added for a group, and for multiple group entries the highest access is retained if the access levels can be compared, otherwise a composite entry is created.
- RACF AUDITOR access is **not** shown.
- Entries for users without access to UNIX because they have no uid or gid are eliminated.

ACL EFFECTIVE

This format setting functions like the ACL RESOLVE setting with the following differences:

- Instead of using the PHYSICAL_ATTR bits, the ATTR are used. These bits take into account the mount attributes for file system that are mounted. For example, for file systems mounted as read-only, all write access is negated and a check is run for access on higher level directories.
- RACF AUDITOR access is shown, but -no uid- and -no gid- entries are eliminated.

Here are some general guidelines for selecting a format setting:

- Use the EXPLODE format setting to see all members of all groups in the access list (empty groups are kept).
- Use the RESOLVE format setting to see the resolved access for each user.
- Use EFFECTIVE format setting to see the effective access for each user.

VSM: Virtual Storage

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The VSM NEWLIST (NEWLIST TYPE=VSM) describes the Virtual Storage Map. That is, the memory regions that together form virtual storage. This NEWLIST type works both on a *live* z/OS system and a CKFREEZE file produced on such a system.

The VSM NEWLIST describes all storage areas. The CSM NEWLIST describes only the common storage areas. It does not include detailed information on individual common storage areas like the storage area key and subpool values. See "CSM: Common Storage" on page 1009.

Each entry in this NEWLIST represents a storage area region or the slack between two regions, and can be uniquely identified by the fields SYSTEM START.

Field descriptions

The VSM NEWLIST provides the following fields for reporting.

AUDITCONCERN

This field indicates the reason for the audit priority. You should not make use of the exact value of this field. The following audit concern can be returned:
Virtual Storage Audit Concerns: (E)CSA overflow into SQA

AUDITPRIORITY

This numeric field indicates the relative priority of audit concerns. Higher values indicate a higher relative audit priority. For all NEWLIST types, audit priority values map to the following meanings:

Table 568. VSM NEWLIST: Audit priority values and descriptions

Priority	Meaning
40 and greater	Immediate attention required; system security can be circumvented easily.
20 to 39	Review is required; serious security threats might exist.
10 to 19	Review is recommended when time permits.
1 to 9	Informational warnings.
0	No audit concerns identified.

COLLECT_DATETIME

This field contains the time stamp that indicates when the CKFREEZE file for this record was created. When running CARLa commands, if a CKFREEZE file is not provided for the system, the time returned is the current system date and time. This field uses the default output format DATETIME.

COMPLEX

The security complex that contains the system. The complex name can come from the ALLOC COMPLEX parameter or default to a system name.

END

The end address of a storage area. This is either an 8-long (4-byte) hexadecimal number or two 8-long hexadecimal numbers separated by an underscore for 8 byte addresses (possibly) situated above the 4 GB threshold.

FILLED

For the CSA and ECSA storage areas, this field contains the percentage used. If 100% is used, there is most likely an overflow into SQA or ESQA; this is noted by the AUDITCONCERN field.

LENGTH

The length of the storage area. This is a decimal number of up to 20 digits.

START

The start address of a storage area. This value is either an 8-long (4-byte) hexadecimal number or two 8-long hexadecimal numbers separated by an underscore for 8 byte addresses, possibly situated above the 4 GB bar. This field also shows whether the address has a high-order fullword in the operating system or not.

This option does not support sorting information by address. If this function is required, use the `START64` option.

START64

The start address of a storage area in a 64 bit number. This is formatted as two 8-long hexadecimal numbers separated by an underscore for 8 byte addresses (possibly) situated above the 4 GB bar. Use this field to sort by address.

SYSTEM

The name of the system. For MVS systems, this is equal to the SMF system id. The field length is 8 characters for compatibility with other NEWLIST types.

TYPE

A string indicating the virtual storage area type. Table 569 lists the possible TYPE values and their meaning. Areas starting with an *E* reside above 16 MB in virtual storage and areas starting with an *X* reside above 4 GB virtual storage. The name can be followed by `slack` to indicate a slack area, or gap between two storage areas.

Table 569. VSM: Virtual Storage: Storage area types and descriptions

TYPE value	Meaning
CSA	Common Storage Area
ECSA	Extended Common Storage Area
EFLPA	Extended Fixed Link Pack Area
EMLPA	Extended Modified Link Pack Area
ENUC RO	Read-only Extended Nucleus Area
ENUC RW	Writable Extended Nucleus Area
EPLPA	Extended Pageable Link Pack Area
EPVT	Extended Private Area
ESQA	Extended System Queue Area
FLPA	Fixed Link Pack Area
JAVA	JAVA Heap Storage Area
MLPA	Modified Link Pack Area
NUC RO	Read-only Nucleus Area
NUC RW	Writable Nucleus Area
PLPA	Pageable Link Pack Area
PSA	Prefix Storage Area
PVT	Private Area
SQA	System Queue Area
XCSA	Extended Common Storage Area above the bar
XLPVT	Extended Private Storage Area above the bar

ZSECNODE: zSecure Server nodes

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
			•	•	•	•

The `ZSECNODE NEWLIST (NEWLIST TYPE=ZSECNODE)` provides information about the zSecure Server obtained from the zSecure Address space.

Field descriptions

You can use the following fields to select and create audit reports for the zSecure-Server configuration.

CKNSERVE_LEVEL
The packaging level of the CKNSERVE server program. The field length is 8 characters.

CKNSERVE_VRM
Shows the version, release, and modification level of the CKNSERVE Server program (`V.R.M`). The field length is 8 characters.

DEFAULT_COMPLEX
Shows the value for the complex that is used by the program, if the complex value is not specified by the user. The field length is 8 characters.

HWNAME
The hardware name (if available) where the system runs. The field length is 8 characters.

IPNAME
The system host name as specified in the zSecure Server configuration file. The following formats are accepted:

- The fully-qualified domain name is the preferred format, for example: `hostname.domain.name`
- The IPv4 format, for example: `10.0.0.1`
- The IPv6 format, for example: `fe80:0:0:0:200:f8ff:fe21:67cf`

This field is empty for those systems that can only be connected through RRSF.

IPADDRESS
The resolved IP-address of the system host name. The following formats are accepted:

- The IPv4 format, for example: `10.0.0.1`
- The IPv6 format, for example: `fe80:0:0:0:200:f8ff:fe21:67cf`

This field is empty for those systems that can only be connected through RRSF.

IPPORT
The IP port number specified for the system. This value is the port number on which the zSecure Server is listening for incoming connections. For remote systems, the `IPPORT` value represents the port number that is used to connect to the remote zSecure Server. This field is empty for those systems that can only be connected through RRSF.

LAST_CONNECT
Timestamp field that shows when the last communication from this system was received by the local zSecure Server.

LAST_CONNECT_ATTEMPT
Timestamp field that shows when the last communication attempt was made by the local zSecure server to this system.

LPARNAME
The Logical Partition name where the system runs, if available. The field length is 8 characters.

RRSFNODE
The RRSF node name for the remote system. The node name is used for sending RACF commands if the user selects RRSF for command direction.This field is empty for those systems on which RRSF is not active.

RRSF_ACTIVE
Flag field that specifies if the RRSF node is active on the current system.

RRSF_DEFINED
Flag field that signals that the RRSF node has been defined locally. If this flag value is *YES*, sending RACF commands to the RRSF node is possible. If this flag value is *NO*, the RRSF node is not defined locally. The missing definition for the RRSF node might be caused by a configuration error, or the node might be a member of a separate RRSF network.

RRSF_LOCAL
Flag field that signals that this system is the local RRSF node, or this system is part of the same multisystem RRSF node as the current system. If the RRSF node is a multisystem node and is also the current system (`zsec_local=yes`) the value for the flag is *YES* for all other systems in the same RRSF node. One of these systems might be designated as `RRSF_MAIN`. If the `MAIN` system is not included as a system in the zSecure network, the `MAIN` system might be absent.

RRSF_MAIN
Flag field that identifies the `MAIN` system in the RRSF multisystem node. The concept is like the preferred system in the zSecure node. Only one system can be assigned as `MAIN` system in an RRSF node.

RRSF_USERID
Shows the associated userid value that is used as the default for command routing and authorization on the `RRSFNODE` and a possible matching `ZSECNODE`. The value of this field is dependent on the userid that creates the report.

SMFID
Shows the SMF system id, which is the value specified for the `SID` parameter in the active `SMFPRM`*xx* member in `PARMLIB`. This value identifies SMF records and is present in storage in the `SMCASID` field. In many zSecure `NEWLIST`s, this field is called `SYSTEM`.

SYSCLONE
The `&SYSCLONE` variable that identifies a system within a SYSPLEX. The field length is 2 characters.

SYSNAME
The z/OS system name that is in the `CVTSNAME` field in memory. The value might be derived from the `SYSNAME` parameter in the active IEASYS member in PARMLIB.

SYSPLEX
This field shows the sysplex name. The field length is 8 characters.

VMUSERID
The VM guest user ID hosting the system, if available. The field length is 8 characters.

ZSECNODE
The zSecure node name that describes all systems sharing the same RACF database. The value can be compared to the RRSF node name for a multisystem node. This field is empty for those systems that can only be connected through RRSF.

ZSECSYS
The zSecure system name that describes a single system. This field is empty for those systems that can only be connected through RRSF.

ZSEC_ACTIVE
Flag field that indicates if a *remote* zSecure system (`ZSECSYS`) is connected to the

local server. *YES* indicates a current connection. *NO* indicates that the system is not currently connected. The connection might have been dropped due to inactivity.

If the zSecure system represents the local server, the value of the flag is usually *NO*. The value is *YES* if the local server needed to connect to itself, for example to process a data request from a local client.

ZSEC_LOCAL
Flag field that signals that the current zSecure system record represents the local system. Only one system in the report can have a value of *YES*.

ZSEC_PREFERRED
Flag field that signals that the zSecure system is the preferred system for this zSecure node. This flag can be YES for only a single system within a zSecure node.

ZSEC_VERIFIED
Flag field that signals that the zSecure system has been contacted, and that the verification of the system information was successful. The system does not need to be currently active, but can be contacted if needed.

Chapter 14. CKGRACF Command Language

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
		•	•			

The CKGRACF program is part of IBM Security zSecure Admin. It is used for handling Queued commands (like temporary access), revoke or resume schedules, User data fields and various other functions that require updating RACF profiles. This program is also used by IBM Security zSecure Visual.

All CKGRACF commands and command options can be abbreviated to the shortest unique prefix, with a minimum of two characters. For example, the AUTHORITY command can be abbreviated as AU. Within the USER command, the INTERVAL option can be abbreviated as IN, and the PWSET option can be abbreviated as PWS. The only command that cannot be abbreviated is the CMD command, which does not accept abbreviations of the command or the command options.

This section provides information about the syntax and use of the CKGRACF commands and also provides a command reference. For more information, select the desired topic.

String conversion in CKGRACF

In all commands, *string values* can be specified in the following ways:

- Unquoted: The string is converted to uppercase and must not contain quotes, double quotes, or backquotes.
- Quoted: The string must not contain double quotes. The value can be appended with one of the optional conversion characters listed in Table 570 on page 1500.
- Double-quoted: The string must not contain single quotes. The value can be appended with one of the optional conversion characters listed in Table 570 on page 1500.
- Backquoted: The string must not contain backquotes. The value can be appended with one of the optional conversion characters listed in Table 570 on page 1500.

Table 570 on page 1500 lists the optional string conversion characters that can be appended to string values. When a conversion character is present, the value is converted based on the specified character.

Table 570. String conversion characters

Character	Meaning
C	Keep case exact
X	Convert string from hexadecimal
none	Convert string to uppercase

Note that when mixed case password support is enabled, passwords supplied on the `PWDEFAULT PASSWORD()` and `PWSET PASSWORD()` commands are not automatically converted to uppercase. Also, password phrases supplied on `PWSET PHRASE()` are never converted to uppercase.

Number conversion in CKGRACF

In all commands, *numerical values* can be specified in the following ways:

- Unquoted: The number must be a decimal.
- Quoted, double-quoted, or backquoted: The number can be decimal, hexadecimal, or binary. The value can be appended with one of the optional conversion characters listed in Table 571.

Table 571 lists the optional number conversion characters that can be appended to numerical values. When a conversion character is present, the value is converted based on the specified character.

Table 571. Number conversion characters

Conversion Character	Meaning
B	Convert from binary
F	Convert from decimal
X	Convert from hexadecimal
none	Convert from decimal

Profile conversion in CKGRACF

In all commands the profile can be specified in the following ways:

- Unquoted: The profile is taken as is. No prefixes are added, and the profile is treated as if it were quoted.
- Quoted, double-quoted, or backquoted: The profile can be appended with one of the optional conversion characters listed in Table 572.

Table 572. Profile conversion characters

Conversion Character	Meaning
C	Keep case exact
D	Profile is discrete
G	Profile is generic
X	Convert profile from hexadecimal

Date specification in CKGRACF

In all commands, dates can be specified in the following formats:

- European format (`DDMMMYY`, `DD-MMM-YY`, `DD/MMM/YY`, `DDMMMYYYY`, `DD-MMM-YYYY`, `DD/MMM/YYYY`)
- ISO format (`YYYY-MM-DD or YYYY/MM/DD`)
- Julian-date format: (`YYDDD or YYYY/DDD`)
- To specify the current date, use the special value `TODAY`.

Two-digit years are usually considered to be an error unless the error message has specifically been suppressed at the request of the user using the SUPPRESS MSG=729 command. If the case, two-digit years are interpreted as prefixed with 19.

Command separator restrictions

To issue multiple CKGRACF commands, use the ; character (semicolon) to separate each command. The only exceptions to this syntax is when specifying CMD commands without DLM option. these commands only accept end-of-line as the end of the command. If you want to specify DEBUG flags, it is advisable to put this command before all others.

Reason keywords in CKGRACF

All commands except LIST and SHOW have a REASON keyword to log extra information along with the command itself. The syntax for the reason specification is:

`REASON(`*`reason`*`)`

where *reason* is a string. See also "String conversion in CKGRACF" on page 1499.

- A maximum of 215 characters. (See "USER" on page 1533)
- Most *reason* strings can have a maximum of 233 characters. However, a *reason* string which is part of a SCHEDULE subcommand can have a maximum of 215 characters. See "USER" on page 1533.

Note that the log string in a RACF SMF record can have a maximum of 255 characters. As a result, some parts of CKGRACF commands with more than 255 characters, notably commands with very long REASON strings, are not logged. To reduce instances of truncating CKGRACF command output in the logs, use shorter REASON strings to help limit the size of the commands to 255 characters.

JCL sample for CKGRACF

The SCKRSAMP library contains the JCL sample C2RJXCKG procedure that can be used to do a single CKGRACF run. You can use the instream CKGIN data set to pass the CKGRACF command(s) to procedure C2RCXCKG. For example, to list IBMUSER, modify the instream DD statement as shown in the following code sample.

```
//C2RJXCKG EXEC C2RCXCKG,CONFIG=C2R$PARM
//CKGIN    DD *
  LIST USER IBMUSER
```

CKGRACF command reference

The following CKGRACF command reference provides information descriptions and syntax information for all CKGRACF commands.

ACCESS

The ACCESS command determines the access of a specified user or group on a specified resource or resource profile, using the best matching generic profile available.

The ACCESS command has the following syntax:

```
ACCESS id class profile [ type ] [ REASON(reason) ]
id       A userid or groupid
class    Any resource profile class
profile  A resource profile
type     An optional profile type; see below
reason   A reason ("Reason keywords in CKGRACF" on page 1501)
```

If the profile name contains generic characters (*%&), the profile is automatically considered generic. To override this behavior, you can either specify the DISCRETE keyword, or use the D suffix notation for defining a discrete profile.

The profile *types* for CKGRACF access are listed in Table 573.

Table 573. Profile types for CKGRACF ACCESS

Profile Type	Meaning
ASIS	Profile is as-is
DISCRETE	Profile is discrete
GENERIC	Profile is generic

The ACCESS command requires access to the command profile shown in Table 574.

Table 574. Command access checks for CKGRACF ACCESS

Resource name checked	Access required
CKG.CMD.ACCESS.ALL	READ

The ACCESS command is not subject to scope checks.

Notes:

- Discrete profiles are not taken into account for the class DATASET. Only the matching generic profile is checked and shown.
- The command attempts to return the access the user has through the access list, conditional access list or UACC. It ignores Global Access Table, RACF exits, and default return code as defined in the Class Descriptor Table. It will issue a message with RACROUTE REQUEST=AUTH return codes when the RACROUTE call returned with unexpected return codes. See also “DEBUG” on page 1511.

ALLOC

This command can be used to specify file allocation options. All options except LICENSE can only be specified in the parameter string.

You can specify one or more parameters, separated by blanks or commas. The parameters are:

DD=*ddname*
This parameter is used in conjunction with TYPE=INPUT and DSN=*dsn* parameters. The ddname is the MVS DD name to use for the dynamic allocation of data set *dsn*.

DSN=*dsn*
Used in conjunction with TYPE=INPUT and DD=ddname parameters, this parameter provides value for the data set name to be dynamically allocated. The *dsn* value can be enclosed in quotes. No userid is prefixed to *dsn* if the quotes are omitted. The *dsn* value specified cannot contain a member name in parentheses, nor can it be a relative member of a generation data group.

ERRDD= *ddname*
Use this parameter to redirect the SYSTERM output to a user-specified *ddname*. This parameter can only be used as a calling parameter in the PARM keyword in JCL. It cannot be used as a command in the input file.

LICENSE= *dsn(member)*
This keyword is present for backward compatibility only. It is ignored.

OUTDD= *ddname*
Use parameter to change the print output file name to a user-specified *ddname*. This parameter can only be used as a calling parameter for the PARM keyword in JCL. It cannot be used as a command in the input file.

TEXTPIPE= *n*
This parameter is valid on the PARM string only. It can be used to ship all remote text files through a UNIX pipe.

TYPE=INPUT
This parameter is used in conjunction with the DD=ddname and DSN=*dsn* parameters. The data set name *dsn* is dynamically allocated for input, using DD name *ddname*.

AUTHORITY

The AUTHORITY command can be used to set, delete, or list a profile's multiple-authority requirement. For an explanation of the multiple-authority system, see “USER” on page 1533. If a profile has no multiple-authority setting stored in the USR field, the system-wide default is used. This default value can be listed using the SHOW CKRSITE command.

The AUTHORITY command has the following syntax:

```
AUTHORITY class profile [ action ] [ REASON(reason) ]

class      Any valid RACF class
profile    Any valid RACF profile
action     One of SINGLE, DUAL, TRIPLE, DEFAULT, or LIST; see below
reason     A reason (See also "Reason keywords in CKGRACF" on page 1501)
```

The following table lists the actions supported:

Table 575. Actions for CKGRACF AUTHORITY

Action	Meaning
DEFAULT	Delete the profile's multiple-authority requirement; the system-wide default will prevail
DUAL	Set the profile's authority-requirement to DUAL
LIST	Show the profile's multiple-authority requirement
SINGLE	Set the profile's authority-requirement to SINGLE
TRIPLE	Set the profile's authority-requirement to TRIPLE

If no action is specified, LIST is used.

The AUTHORITY command requires access to the command profiles shown in the following table.

Table 576. Command access checks for CKGRACF AUTHORITY

Resource name checked	Access required
CKG.CMD.AUTHORITY.*class*	READ for the LIST option, UPDATE for all other options.

The AUTHORITY command is not subject to scope checks.

CKGAUTH

The CKGAUTH command can be used to set, delete, or list a profile's *internal* multiple-authority requirement.

Every one of the CKG.RAC, CKG.SCP and CKG.SCPASK profiles can contain an internal multiple-authority setting. This setting will be evaluated by the CMD command to determine the eventual multiple-authority requirement for the command as a whole. It is currently not used by the USER command.

If a profile has no internal multiple-authority setting stored in the USR field, the system-wide default is used. This default can be listed using the SHOW CKRSITE command. For additional explanation of the internal multiple-authority system, see "CMD" on page 1505 and "Racfdata profiles" on page 1568.

The CKGAUTH command has the following syntax:

```
CKGAUTH class profile [ action ] [ REASON(reason) ]

class       Any valid RACF class
profile     Any valid RACF profile
action      One of SINGLE, DUAL, TRIPLE, DEFAULT, or LIST; see below
reason      A reason (See also "Reason keywords in CKGRACF" on page 1501)
```

The following table shows the actions supported:

Table 577. Actions for CKGRACF CKGAUTH

Action	Meaning
DEFAULT	Delete the profile's multiple-authority requirement; the system-wide default will prevail
DUAL	Set the profile's authority-requirement to DUAL
LIST	Show the profile's multiple-authority requirement

Table 577. Actions for CKGRACF CKGAUTH (continued)

Action	Meaning
SINGLE	Set the profile's authority-requirement to SINGLE
TRIPLE	Set the profile's authority-requirement to TRIPLE

If no action is specified, LIST is used.

The CKGAUTH command requires access to the command profiles shown in the following table.

Table 578. Command access checks for CKGRACF CKGAUTH

Resource name checked	Access required
CKG.CMD.CKGAUTH.*class*	READ for the LIST option, UPDATE for all other options.

The CKGAUTH command is not subject to scope checks.

CNGAUTH is an alias for the CKGAUTH command.

CMD

The CMD command is used to run or queue native RACF commands. The CMD can take the following forms:

- `CMD ASK`
- `CMD REQUEST`
- `CMD EXECUTE`

The CMD ASK and REQUEST forms use the CKGRACF defined scope and multiple-authority possibilities. See "USER" on page 1533. The CMD EXECUTE command form uses the RACF scope.

The REMOVE, CONNECT and PERMIT commands can also be reversed after a certain time period.

The CMD command has the following syntax:

```
CMD [ options ] command

options    Any CMD option; see below
command    Any valid and supported RACF command (may be continued on
           next line by a trailing +)
```

A trailing plus sign (+) is used to indicate that the RACF command is continued on the next line, called a *continuation line*. Blanks after a trailing plus sign and at the beginning of continuation lines are ignored. Significant blanks have to be placed in front of a trailing plus sign.

Table 579 shows the options available for the CMD command:

Table 579. Options for CKGRACF CMD

Option	Meaning
AT *date1*	Execute *command* at date *date1*.

Table 579. Options for CKGRACF CMD (continued)

Option	Meaning
AFTER *len*	Execute *command* after *len* days from today. This option is converted to "AT *today+len*" so after today it is still clear which day the command is to be executed.
FOR *len* LEN *len*	Apply *command* for *len* days, (maximum 500 days).
UNTIL *date2*	Apply *command* until date *date2*.
NODE(zsecnode)	A zSecure Server ZSECNODE name to route the command to.
REASON(*reason*)	A reason (See also "Reason keywords in CKGRACF" on page 1501)
DLM	The DLM keyword is followed by the rest of the CMD command surrounded by matching sequences of consecutive double quotes. The command ends with the right delimiter sequence. This delimiter can be left off the command in which case the command terminates at the end of the line.
action	A queued-command action.

If no *date1* is specified, the start date of a temporary command will be the date it is actually executed. The FOR and LEN options will cause the reversed command to be executed *len* days after this execution date. If no *date2* is specified, the command is not reversed, unless a FOR or LEN option is defined to calculate *date2*.

A command that is applied for a certain period, will try to restore the situation existent at *date1* as much as possible on *date2*.

The AT and AFTER keywords are mutually exclusive. The FOR, LEN, and UNTIL keywords are mutually exclusive as well.

The following example denotes a valid sequence of two CKGRACF commands, illustrating the use of the DLM option.

```
CMD DLM """ EXECUTE ALU SOMEUSER DATA('"SING+
LE " DOUBLE "" TEST') """ ; LIST USER SOMEUSER
```

The next example has a syntax error because its plus sign (+) character is not part of the RACF command.

```
CMD DLM " EXECUTE ALU SOMEUSER DATA('TEST') " +
; LIST USER SOMEUSER
```

The following *queued-command actions* can be specified. See "Actions on queued commands" on page 1550 for more detailed information.

ASK
REQUEST
SECOND APPROVE
SECOND DENY
SECOND HOLD
COMPLETE APPROVE
COMPLETE DENY
COMPLETE HOLD

WITHDRAW
EXECUTE

The ASK, REQUEST, SECOND, COMPLETE and WITHDRAW actions are currently only allowed with the RACF commands REMOVE, CONNECT and PERMIT.

The *action* EXECUTE runs the *command* under the current userid, with the user's own permissions. Most RACF commands and HELP can be executed in this manner. A notable exception is the RVARY command.

The default action for the CMD command is ASK.

The CMD command requires access to a command profile that includes both an *action qualifier* and the *command*. The basic format of the resource name checked is CKG.CMD.CMD.*action.command.* Action qualifiers are:

- ASK for ASK
- REQ for REQUEST and WITHDRAW
- SEC for SECOND
- CMP for COMPLETE
- EX for EXECUTE

Table 580 provides the complete list of command access checks.

Table 580. Command access checks for CKGRACF CMD

Command	Action	Resource name checked	Access required
ADDGROUP	EXECUTE	CKG.CMD.CMD.EX.ADDGROUP	UPDATE
ADDSD	EXECUTE	CKG.CMD.CMD.EX.ADDSD	UPDATE
ADDUSER	EXECUTE	CKG.CMD.CMD.EX.ADDUSER	UPDATE
ALTDSD	EXECUTE	CKG.CMD.CMD.EX.ALTDSD	UPDATE
ALTGROUP	EXECUTE	CKG.CMD.CMD.EX.ALTGROUP	UPDATE
ALTUSER	EXECUTE	CKG.CMD.CMD.EX.ALTUSER	UPDATE
CONNECT	ASK	CKG.CMD.CMD.ASK.CONNECT	UPDATE
CONNECT	COMPLETE	CKG.CMD.CMD.CMP.CONNECT	UPDATE
CONNECT	EXECUTE	CKG.CMD.CMD.EX.CONNECT	UPDATE
CONNECT	REQUEST or WITHDRAW	CKG.CMD.CMD.REQ.CONNECT	UPDATE
CONNECT	SECOND	CKG.CMD.CMD.SEC.CONNECT	UPDATE
DEFINE	EXECUTE	CKG.CMD.CMD.EX.DEFINE	UPDATE
DELDSD	ASK	CKG.CMD.CMD.ASK.DELDSD	UPDATE
DELDSD	COMPLETE	CKG.CMD.CMD.CMP.DELDSD	UPDATE
DELDSD	EXECUTE	CKG.CMD.CMD.EX.DELDSD	UPDATE
DELDSD	REQUEST or WITHDRAW	CKG.CMD.CMD.REQ.DELDSD	UPDATE
DELDSD	SECOND	CKG.CMD.CMD.SEC.DELDSD	UPDATE
DELETE	EXECUTE	CKG.CMD.CMD.EX.DELETE	UPDATE
DELGROUP	EXECUTE	CKG.CMD.CMD.EX.DELGROUP	UPDATE
DELUSER	EXECUTE	CKG.CMD.CMD.EX.DELUSER	UPDATE

Table 580. Command access checks for CKGRACF CMD (continued)

Command	Action	Resource name checked	Access required
HELP	EXECUTE	CKG.CMD.CMD.EX.HELP	READ
LISTDSD	EXECUTE	CKG.CMD.CMD.EX.LISTDSD	READ
LISTGRP	EXECUTE	CKG.CMD.CMD.EX.LISTGRP	READ
LISTUSER	EXECUTE	CKG.CMD.CMD.EX.LISTUSER	READ
PASSWORD	EXECUTE	CKG.CMD.CMD.EX.PASSWORD	UPDATE
PERMIT	ASK	CKG.CMD.CMD.ASK.PERMIT	UPDATE
PERMIT	COMPLETE	CKG.CMD.CMD.CMP.PERMIT	UPDATE
PERMIT	EXECUTE	CKG.CMD.CMD.EX.PERMIT	UPDATE
PERMIT	REQUEST or WITHDRAW	CKG.CMD.CMD.REQ.PERMIT	UPDATE
PERMIT	SECOND	CKG.CMD.CMD.SEC.PERMIT	UPDATE
RACDCERT	EXECUTE	CKG.CMD.CMD.EX.RACDCERT	UPDATE
RACLINK	EXECUTE	CKG.CMD.CMD.EX.RACLINK	UPDATE
RACMAP	EXECUTE	CKG.CMD.CMD.EX.RACMAP	UPDATE
RALTER	EXECUTE	CKG.CMD.CMD.EX.RALTER	UPDATE
RDEFINE	EXECUTE	CKG.CMD.CMD.EX.RDEFINE	UPDATE
RDELETE	ASK	CKG.CMD.CMD.ASK.RDELETE	UPDATE
RDELETE	COMPLETE	CKG.CMD.CMD.CMP.RDELETE	UPDATE
RDELETE	EXECUTE	CKG.CMD.CMD.EX.RDELETE	UPDATE
RDELETE	REQUEST or WITHDRAW	CKG.CMD.CMD.REQ.RDELETE	UPDATE
RDELETE	SECOND	CKG.CMD.CMD.SEC.RDELETE	UPDATE
REMOVE	ASK	CKG.CMD.CMD.ASK.REMOVE	UPDATE
REMOVE	COMPLETE	CKG.CMD.CMD.CMP.REMOVE	UPDATE
REMOVE	EXECUTE	CKG.CMD.CMD.EX.REMOVE	UPDATE
REMOVE	REQUEST or WITHDRAW	CKG.CMD.CMD.REQ.REMOVE	UPDATE
REMOVE	SECOND	CKG.CMD.CMD.SEC.REMOVE	UPDATE
RLIST	EXECUTE	CKG.CMD.CMD.EX.RLIST	READ
SEARCH	EXECUTE	CKG.CMD.CMD.EX.SEARCH	READ
SETROPTS	EXECUTE	CKG.CMD.CMD.EX.SETROPTS	UPDATE

In addition, the target profile must be within the `racfdata-scope` of the command user. See "CKGRACF authority checks" on page 1559 and "Racfdata profiles" on page 1568.

Table 581. Racfdata scope checks for CKGRACF CMD

Resource name checked	Access required
CKG.RAC.OWN.*class.segment.field*	READ for LIST commands; UPDATE for all other options.
CKG.RAC.ALL.*class.segment.field*	READ for LIST commands; UPDATE for all other options.

Table 581. Racfdata scope checks for CKGRACF CMD (continued)

Resource name checked	Access required
CKG.RAC.SCP.*class.segment.field*	READ fo LIST commands; UPDATE for all other options.
CKG.SCP.ID.*userid.owner.dfltgrp*	READ for LIST commands; UPDATE for all other options.
CKG.SCP.ID.*groupid.owner*	READ for LIST commands; UPDATE for all other options.
CKG.SCP.G.*groups...*	READ for LIST commands; UPDATE for all other options.
CKG.SCP.U.*user.groups...*	READ for LIST commands; UPDATE for all other options.
CKG.SCPASK.ID.*userid.owner.dfltgrp*	READ for LIST commands; UPDATE for all other options.
CKG.SCPASK.ID.*groupid.owner*	READ for LIST commands; UPDATE for all other options.
CKG.SCPASK.G.*groups...*	READ for LIST commands; UPDATE for all other options.
CKG.SCPASK.U.*user.groups...*	READ for LIST commands; UPDATE for all other options.

Every one of the CKG.RAC, CKG.SCP and CKG.SCPASK profiles can contain an internal multiple-authority setting. This setting will be evaluated by the CMD command to determine the eventual multiple-authority requirement for the command as a whole.

The actual multiple-authority requirement for the command will be the highest of the multiple-authority requirement set on the target profile, and the internal multiple-authority requirements set on the CKG.RAC, CKG.SCP and CKG.SCPASK profiles.

The internal multiple-authority requirement for a profile can be set using the CKGAUTH command. See "CKGAUTH" on page 1504).

Warning about passwords

Depending on the audit level of the CKG.CMD.CMD profile, RACF commands issued through CMD or USER PWSET can be logged in SMF and written to the job output if CKGRACF is run in batch. These commands can show passwords and password phrases.

When a PASSWORD or PHRASE parameter is recognized in a RACF command, the secret value is replaced by a question mark. To prevent password collection from the SMF or the job log, make sure that the PASSWORD or PHRASE parameter is not abbreviated to fewer than 4 positions and that the left parenthesis is coded immediately following the parameter with no spaces. The following examples shows the logging for different formats:

`ALTUSER IBMUSER PASS(1234)` is logged as `ALTUSER IBMUSER PASS(?)` with no password displayed.

`ALTUSER IBMUSER PAS(1234)` is logged as-is to SMF, displaying the password.

`ALTUSER IBMUSER PASSWORD (1234)` includes a blank before the opening parenthesis and is logged as-is, displaying the password.

Comments

A few comments regarding the supported RACF commands;

- For the PERMIT and DELDSD commands, the DATASET profiles are prepended with the TSO-prefix, if it is available, and then put in quotes before queueing. If the DATASET is already enclosed with quotes, this does not apply.
- The *action* REQUEST can be abbreviated to REQ, SECOND can be abbreviated to SEC, COMPLETE can be abbreviated to CMP and EXECUTE can be abbreviated to EX or EXEC.
- The target for scope checking and storing of a queued command is chosen as logical as possible. For CONNECT and REMOVE this is the GROUP they act on; This to ensure that on deletion of the GROUP all related queued commands will be purged, too. For DELDSD, PERMIT, and RDELETE commands, it is the resource the command pertains to. This will also assure the purging of all related queued commands on deletion of the resource.

Restrictions

The following restrictions apply to the CMD command:

- The CMD *options* can not be abbreviated
- RVARY is not supported by EXECUTE.
- CONNECT, DELDSD, PERMIT, RDELETE, and REMOVE are the only supported RACF commands for ASK and REQUEST.
- The PERMIT command only supports a single userid and a single access definition for temporary commands (commands with an UNTIL date, or a LEN or FOR period defined).
- The CONNECT and REMOVE commands only support a single userid.
- The PERMIT command doesn't support the FROM parameter for a temporary command.
- CONNECT, PERMIT and REMOVE will restore the situation that exists at execution when UNTIL, FOR or LEN is specified.
- DELDSD and RDELETE cannot be combined with UNTIL, FOR, and LEN.
- The RACF command parser ignores characters between a semicolon and the end of the line. A CMD command can therefore only be followed by a ; command separator and another CKGRACF command on the same line if its RACF subcommand is delimited using the DLM option.

COMMENT

This command basically does nothing at all. It gets logged as any other normal CKGRACF command and only accepts one parameter; REASON (See also “Reason keywords in CKGRACF” on page 1501). This command can be used to log a comment in between other commands.

The COMMENT command has the following syntax:

```
COMMENT [ REASON(reason) ]
reason      A reason (See also "Reason keywords in CKGRACF" on page 1501)
```

The COMMENT command requires access to the command profiles shown in the following table.

Table 582. Command access checks for CKGRACF COMMENT

Resource name checked	Access required
CKG.CMD.COMMENT	READ

The COMMENT command is not subject to scope checks.

DEBUG

This command is meant to explore the working of CKGRACF or diagnose problems in its operation. It should not be used in any application visible to end-users. If you need additional details, contact IBM software support.

You can specify one or more parameters after the DEBUG command, separated by blanks or commas. The parameters are:

ICHEINTY
Print the ICHEINTY return code, reason code, and a short explanation after each failed ICHEINTY call. Message numbers CKG407I, CKG408I, and CKG409I. See the 'Security Server RACF Macros and Interfaces' manual for additional information on the ICHEINTY result codes.

RACFMSG
Do not inhibit RACF messages, for example make all RACROUTE REQUEST=AUTH calls with MSGSUPP=NO instead of the CKGRACF default MSGSUPP=YES. This results in ICH408I and other messages being printed in the job log and system log. See the 'Security Server RACF Messages and Codes' manual for additional information on the RACF messages.

RACHECK
Print the resource name and access level checked before each RACROUTE REQUEST=AUTH call, and the profile name found after each call. The message numbers are CKG402I and CKG410I.

SAFRC
Print the SAF return code, RACF return code, and RACF reason code after each RACROUTE call. The message also gives a rough indication of the request type. Message numbers CKG401I, CKG403I, CKG404I, CKG405I, and CKG406I. See the 'Security Server RACROUTE Macro Reference' manual, in the section indicated by the request code, for additional information on the RACROUTE result codes.

The DEBUG command does not require access to command profiles and is not subject to scope checks.

FIELD

The FIELD command can be used to set or list a limited number of fields in user profiles that cannot be set by the RACF commands. It is intended for use by system programmers and (central) RACF administrators.

The FIELD command has the following syntax:

```
FIELD class profile action field(value) ... [ REASON(reason) ]

class                     Must be USER.
profile                   Any valid RACF userid.
action                    One of ADD, DELETE, LIST, REPLACE, or SET.
field                     The name of a supported field, possibly
field(value)              followed by one or more field-values
field(old-value,new-value) in parentheses, see the table below.
reason                    A reason (Reason keywords in CKGRACF)
```

A field *value* can be specified as a string, quotes and conversions are allowed. The field *action* determines whether a field value is allowed, according to the following table.

Table 583. Actions for CKGRACF FIELD

Action	Values	Effect	Example
ADD	one	Set the field to the value	ADD TCOMMAND(MYCLIST)
DELETE	none	Set the field to its default value	DELETE TCOMMAND
DELETE	one	Set the field to its default value if the current value matches the parameter	DELETE TCOMMAND(MYCLIST)
LIST	none	List the field	LIST LJDATE
REPLACE	two	Replace the value of the field if the current value matches the parameter	REPLACE TCOMMAND(OCLIST,NCLIST)
SET	one	Set the field to the value	SET TCOMMAND(MYCLIST)

More than one field can be specified in a single FIELD command, but each field can be specified at most once; the same action will be applied to each of the fields in turn. If an error occurs with one of the specified actions, the others will still be processed and might change the profile.

Warning: If an invalid value (or format) id used to set or replace, or if you delete the value of a field, problems can occur.

The FIELD command requires an exact specification of the field in a format that matches the RACF internal representation of the field value. For instance, the TCOMMAND field is a character field, and thus the CKGRACF FIELD command expects the input value to be in character format (or hexadecimal representation thereof). On the other hand, the LJDATE and PASSDATE fields each have a packed decimal value. The only supported way of specifying such a value is via its hexadecimal representation as 'yydddF'x. For LJDATE and PASSDATE, the first character (2 hex digits) specifies the year value, while ddd specifies the julian date. The "F" at the end represents the sign ("F" is defined for Packed Decimal to represent a positive number). A year character between '71'x and '99'x denotes a year in the 20th century, while a year character between '00'x and '70'x denotes a year in the 21th century. For example, '71'x denotes 1971 while '00'x denotes 2000.

The following table summarizes the required formats.

Table 584. Fields for CKGRACF FIELD

Name	Meaning	Length	Format
BINDPW	PROXY segment Bind password	Variable, up to 128 characters	'xxxx...xx'x
BINDPWKY	PROXY segment Bind password mask or encrypt key	71	'xxxx...xx'x
FLAG7	Password or password phrase needed	1	'nn'x
FLAG8	OIDCARD required	1	'nn'x

Table 584. Fields for CKGRACF FIELD (continued)

Name	Meaning	Length	Format
INTERVAL	Password and password phrase interval	1	'nn'x
LJDATE	Last-use date	3	'yydddF'x
LJTIME	Last-use time	4 .	'hhmmsscc'x
PASSASIS	Password mixed case	1	'nn'x
PASSDATE	Password change date	3	'yydddF'x
PASSWORD	Encrypted password	8	'xxxxxxxxxxxxxxxx'x
PHRASE	Encrypted pass phrase	Variable, up to 100 characters	'xxxx...xx'x
PHRDATE	Pass phrase change date	3	'yydddF'x
REVOKECT	Revoke counter	1	'nn'x
SSKEY	SSIGNON segment Session key	Variable, up to 255 characters	'xxxx...xx'x
SESSKEY	SESSION segment Session key	Variable, up to 8 characters	'xxxx...xx'x
TCOMMAND	TSO start-up command	Variable, up to 80 characters	'quoted string' or unquoted_string
TUPT	TSO UPT data	Variable, up to 255 characters	'xxxx...xx'x

Changing the PASSDATE or PHRDATE field while running RRSF causes the last use date/time and the last connect date/time to be updated to a time dependent on the response time of RRSF.

The TCOMMAND and TUPT fields are intended to be used for SYS1.UADS to RACF migration; the LJDATE, LJTIME, PHRASE, PASSWORD, INTERVAL, PASSDATE, PHRDATE and REVOKECT fields can be used when merging RACF databases. Security zSecure also generates CKGRACF commands to update the TCOMMAND field. The length specified in the preceding table must match the length of the value supplied to the FIELD command; if the length is different, an error message is issued.

Notes:

1. In the restructured database, adding a TCOMMAND or TUPT field creates a TSO segment if the profile does not have one yet.
2. If the LJDATE field is set to an invalid date, RACF might abend when the user attempts to logon or when a LISTUSER command is executed.
3. If the INTERVAL field is set to 0, then a user must change his password at each logon.
4. The FIELD command requires access to the command profiles listed in Table 585. The access required is different for different fields.

Table 585. Command access checks for CKGRACF FIELD

Field	Resource name checked	Access required
INTERVAL	CKG.CMD.FIELD.INTERVAL	READ for the LIST option, UPDATE for all other options.
LJDATE	CKG.CMD.FIELD.LJDATE	READ for the LIST option, UPDATE for all other options.

Table 585. Command access checks for CKGRACF FIELD (continued)

Field	Resource name checked	Access required
LJTIME	CKG.CMD.FIELD.LJTIME	READ for the LIST option, UPDATE for all other options.
PASSASIS	CKG.CMD.FIELD.PASSASIS	READ for the LIST option, UPDATE for all other options.
PASSDATE	CKG.CMD.FIELD.PASSDATE	READ for the LIST option, UPDATE for all other options.
PASSWORD	CKG.CMD.FIELD.PASSWORD (See "Note about password-related fields.")	READ for the LIST option, UPDATE for all other options.
PHRASE	CKG.CMD.FIELD.PHRASE (See "Note about password-related fields.")	READ for the LIST option, UPDATE for all other options.
PHRDATE	CKG.CMD.FIELD.PHRDATE	READ for the LIST option, UPDATE for all other options.
REVOKECT	CKG.CMD.FIELD.REVOKECT	READ for the LIST option, UPDATE for all other options.
TCOMMAND	CKG.CMD.FIELD.TCOMMAND	READ for the LIST option, UPDATE for all other options.
TUPT	CKG.CMD.FIELD.TUPT	READ for the LIST option, UPDATE for all other options.
FLAG7	CKG.CMD.FIELD.FLAG7	READ for the LIST option, UPDATE for all other options.
FLAG8	CKG.CMD.FIELD.FLAG8	READ for the LIST option, UPDATE for all other options.

Note:

The FIELD command is not subject to scope checks. Because the PASSWORD and PHRASE fields can be used to list all users' encrypted password information, make sure that access to the field is restricted. Access to these fields should be only be granted to users who are also allowed to read the active RACF database in unrestricted mode.

Example

An example of the FIELD command is taken from the RECREATE USER CARLa script (member CKGXRUS in the SCKRCARL library). The CARLa commands in this script generate CKGRACF FIELD commands to recreate the user's password, TSO command, and TSO UPT data fields. To recreate the user's password, a RACF database is required. The following excerpt of CKGXRUS shows CARLa commands to generate CKGRACF FIELD commands to recreate the user's TSO UPT data fields.

```
new nopage f=ckrcmd nulls proflist=users name=ckgtupt    /*QZ0607003*/
  s likelist=idsel s=tso exists(tupt)                    /*QZ0607003*/
  sortlist 'ckgracf field' class key(8) 'set',
           "tupt('" | tupt(hex,0) | "'X)"
```

Part of CARLa script CKGXRUS

The following sample output command is generated by Security zSecure.

```
ckgracf field USER R#OPADM
set tupt('00380000000000000000000001000001D97BD6D7D9D6C207C5D5E4C5D5E40'X)
```

Sample CKGRACF FIELD command generated by Security zSecure

IMBED / INCLUDE

The IMBED or INCLUDE command (abbreviation: I) can be used to include input commands for CKGRACF from a different source than the program/command parameters and the SYSIN file. The INCLUDE commands can be nested, for example, the input commands included can contain another include command. The main use of this command is to include sample or user-defined members or read commands from a file; this can be used to share queries or output displays. Using the INCLUDE command to include a standard installation-defined member is a simple customization option.

The commands are read immediately after the INCLUDE statement ends. After the secondary input source has been exhausted, processing of the original input source is resumed at the token that terminated the INCLUDE statement. The input listing clearly shows the origin of the input commands.

The parameters are:

DDNAME= *file* **FILE=***file*
To imbed the contents of a sequential file or (in combination with the MEMBER parameter) to denote the file containing the member to be imbedded. If MEMBER is specified as well, a partitioned data set (concatenation) must be allocated to the file.

MEMBER= *name*
To imbed the contents of a PDS member. If the DDNAME parameter is also present, the PDS allocated to that file is used. If the DDNAME parameter is omitted, the DDname CKRCARLA is assumed.

MARGINS= *(nn,ll)* **MARGINS(***nn,ll***)**
Set the margins for the included file or member. The default is dependent on the input LRECL and RECFM. For an LRECL=80 RECFM=F file, this results in a default of MARGINS(1,72).

The IMBED command does not require access to command profiles.

LIST

The LIST command can be used to display RACF as well as CKGRACF data and settings for a profile. The CKGRACF settings are stored in the USR field of a profile, and have a USRNM value starting with the characters CNG; the LIST command is used to display USR entries that cannot be set or displayed using the USRDATA command. The CKGRACF settings for a profile can include:

- The profile's multiple-authority requirement (for all profiles)
- Queued commands that have the profile as their target (for all profiles)
- A user's default password (for a user) [22]
- Scheduled revoke and resume actions (for a user)

22. The LIST command indicates that a default password was set; also, when and by whom it was set. The default password is not displayed.

For auditing purposes, the LIST command displays the author, date, and time for each setting.

The LIST command also displays the index (USRNM-value) of unknown reserved USR entries.

Listing the RACF settings is only possible for class USER, and will include (non-exhaustive):

- Last connect/login date and time
- Group access list
- Default group
- Revoke status of user
- PROTECTED attribute
- RESTRICTED attribute

The LIST command has the following syntax:

```
LIST class profile [ option ]
class     Any valid RACF class
profile   Any valid RACF profile
option    One of ALL, RACF, SCHEDULE, TAG [ NOTERM ] [ NOPAGE ] or QUEUE;
see below
```

The following table shows the options supported:

Table 586. Options for CKGRACF LIST

Option	Meaning
ALL	List all RACF and CKGRACF data
RACF	List the RACF data
SCHEDULE	List scheduled resume and revoke actions
TAG [NOTERM] [NOPAGE]	List profile's data in tagged format (See below)
QUEUE	List queued CKGRACF commands

If no option is specified, ALL is used for USER and QUEUE for all other classes.

When the TAG option is followed by NOTERM, the output of the LIST command is not sent to SYSTERM. This can save bandwidth e.g. when the output is transferred from one machine to another. When the NOPAGE option is present, no page headers will be printed between the tagged format lines. This simplifies parsing the output.

The LIST command requires access to the command profile shown in the following table.

Table 587. Command access checks for CKGRACF LIST

Resource name checked	Access required
CKG.CMD.LIST	READ

In addition, the target user must be within the scope of the command user (see "CKGRACF authority checks" on page 1559):

Table 588. Scope access checks for CKGRACF LIST

Resource name checked	Access required
CKG.SCP.ID.*groupid.owner*	READ
CKG.SCP.ID.*userid.owner.dlftgrp*	READ
CKG.SCP.G.*groups...*	READ
CKG.SCP.U.*user.groups...*	READ

Example

```
CKGRACF LIST USER C##CX01

------------ Status of USER C##CX01 on 23Aug2006 08:57 at IPO1 -------------
--------------------------- Inactive PwdExpired ----------------------------

CKG132I 00 No CKGRACF queued command entries found
CKG133I 00 No CKGRACF schedule data entries found
```

Sample output of the LIST command

TAG Format

The TAG option for the LIST command generates a machine readable output with a very specific syntax. Every line of output is defined as follows:

```
X-field verbose value(s)

X         A profile type identifier for field (See below)
field     A RACF field name or a likely other name
verbose   A more verbose description or name for field
value     The value that is stored in field
```

The identifier can have different values for different fields: 'C' for CKGRACF related fields, 'G' for GROUP, 'U' for USER, 'R' for GENERAL RESOURCE, 'D' for DATA SET, 'S' for SCHEDULE information (See also “USER” on page 1533), 'Q' for queued command information (See also “CMD” on page 1505) and 'I' for generic information.

The field *field* has a fixed length of 8 (10 including the indicator) and is right padded with spaces. The field *verbose* has a fixed length of 16 (right padded with spaces). Every non-empty line starting with a space, is a continuation of the previous line. If *value* is a list of other values (for example in a repeat group), the list items will be separated by spaces. If the *values* are strings, every list element will be shown on a new line, starting with a space as described before. Any newline (X'15') character in *value* will be printed as a space if the LIST TAG output is sent to a text pipe. Otherwise, it will be printed as a newline.

A few definitions: string is defined as a series of characters and whitespaces. An integer is defined as a number within the mentioned range. A date is defined as

DDMMMYYYY, where MMM is the month as a three character abbreviation (eg. Mar for March). A time is defined as HH:MM:SS.cc, where HH is hours from 0-23, MM is minutes from 0-59, SS is seconds from 0-59 and cc is hundredths of seconds from 0-99. A queued command stamp is defined as an action, followed by a time stamp of the form USERID DDMMMYYYY HH:MM. An action can contain whitespace.

Table 589. User related fields for CKGRACF LIST

Field	Verbose	Value	Description
U-AUTH	AUTHORITY	CONNECT, CREATE, JOIN, or USE	The authority of the user to the group
U-AUTHDATE	CREATIONDATE	A date (DDMMMYYYY)	The date this user is created
U-AUTHOR	OWNER	A userid or groupid	The owner of the user profile
U-AUTHOR	CONNECTAUTHOR	A userid or groupid	The author of the connect
U-CATEGORY	CATEGORIES	Any number of categories (strings)	A list of all the categories this user can access
U-CLAUTH	CLASSAUTHS	Any number of 8 character classes	A list of all the classes this user can access
U-CONUSRNM	USER	A userid	The userid of a user connected to a group
U-DFLTGRP	DEFAULTGROUP	A groupid	The default group of this user
U-EXPIRED	PASSWORD_EXPIRED	Y or N	Password or password phrase (if any) has expired
U-FLAG1	ADSP	Y or N	The ADSP setting of a user
U-FLAG2	SPECIAL	Y or N	The SPECIAL setting of a user
U-FLAG3	OPERATIONS	Y or N	The OPERATIONS setting of a user
U-FLAG4	REVOKE	Y or N	Whether a user is revoked or not
U-FLAG5	GRPACC	Y or N	The GRPACC setting of a user
U-FLAG6	AUDITOR	Y or N	The AUDITOR setting of a user
U-GRPREVOK	CONNECTREVOKE	Y or N	Whether the user has the REVOKE attribute in the connect group entry. The revoke date, resume date, and REVOKE attribute of the connect group entry are taken into account.
U-CGREVKDT	CONNECTREVOKEDT	Date (DDMMMYYYY)	The revoke date for the connect group entry.
U-CGRESMDT	CONNECTRESUMEDT	Date (DDMMMYYYY)	The resume date for the connect group entry.
U-INACTIVE	REVOKEINACTIVE	INACTIVE or ACTIVE	With INACTIVE the user will be revoked on next logon

Table 589. User related fields for CKGRACF LIST (continued)

Field	Verbose	Value	Description
U-INSTDATA	INSTALLATIONDATA	A string	The installation data of this user
U-LCDATE	LASTCONNECTDATE	A date (DDMMMYYYY)	The date a user has last connected to a group
U-LCTIME	LASTCONNECTTIME	A time (HH:MM:SS.cc)	The time a user has last connected to a group
U-LJDATE	LASTLOGINDATE	A date (DDMMMYYYY)	The date a user has last logged on
U-LJTIME	LASTLOGINTIME	A time (HH:MM:SS.cc)	The time a user has last logged on
U-LOGDAYS	LOGDAYS	S or space, M or space, T or space, W or space, T or space, F or space, and S or space	The days of the week the user can log on
U-NOTRMUAC	NOTERMUACC	Y or N	The user must be authorized with at least READ authority to access a terminal.
U-PASSCHG	PASSWORD_CHANGED	A date (DDMMMYYYY) or empty	The last date this user's password has been changed. It is empty if the password has expired. Also see the U-PHRCHG and U-PASSDATE fields.
U-PASSDATE	PWDLASTCHANGED	A date (DDMMMYYYY) or empty	The last date this user's password or password phrase has been changed. This field is empty if both the password and password phrase have expired. Also, see the U-PASSCHANGE and U-PHRCHG fields.
U-PASSINT	PWDINTERVAL	An integer (0-255), or empty (for a PROTECTED user)	The number of days within which a password or password phrase has to be changed.
U-PGMRNAME	USERNAME	A string	The user's name as stored in PGMRNAME.
U-PHRCHG	PHRASE_CHANGED	A date (DDMMMYYYY) or empty	The last date this user's password phrase has been changed. The field is empty if the password phrase has expired, or the user has no password phrase. (See also U-PASSCHG and U-PASSDT fields.)
U-PROTECT	PROTECTED	Y or N	The PROTECTED setting of a user.
U-RESTRICT	RESTRICTED	Y or N	The RESTRICTED setting of a user.

Table 589. User related fields for CKGRACF LIST (continued)

Field	Verbose	Value	Description
U-REVOKE	REVOKESTATUS	REVOKED or NOT REVOKED	Whether a user is revoked by date.
U-REVOKECT	PWDTRIES	An integer (0-255)	The number of invalid passwords or password phrase attempts since the last logon.
U-SECLABEL	SECLABEL	A string	The security label of this user.
U-SECLEVEL	SECLEVEL	An integer (0-255)	The security level of this user.
U-UACC	CONNECTUACC	ALTER, CONTROL, UPDATE, READ, EXECUTE, or NONE	The default universal access authority assigned to the user for this group.

Table 590. Group related fields for CKGRACF LIST

Field	Verbose	Value	Description
G-AUTH	AUTHORITY	One of the connect authority levels	The authority the user has for this group.
G-AUTHDATE	CREATIONDATE	A date (DDMMMYYYY)	The date the connect from the user to this group was created.
G-AUTHOR	OWNER	A groupid or userid	The owner of this group.
G-CAUTHOR	CONNECTAUTHOR	A groupid or userid	The owner of this connect.
G-CONGRPNM	GROUPNAME	A string	The name of this group.
G-FLAG1	ADSP	Y or N	The ADSP setting of the user for this group.
G-FLAG2	SPECIAL	Y or N	The SPECIAL setting of the user for this group.
G-FLAG3	OPERATIONS	Y or N	The OPERATIONS setting of the user for this group.
G-FLAG5	GRPACC	Y or N	The GRPACC setting of the user for this group.
G-FLAG6	AUDITOR	Y or N	The AUDITOR setting of the user for this group.
G-GRPREVOK	CONNECTREVOKE	Y or N	Whether the user has the REVOKE attribute in the connect group entry. The revoke date, resume date, and REVOKE attribute of the connect group entry are taken into account.
G-CGREVKDT	CONNECTREVOKEDT	Date (DDMMMYYYY)	The revoke date for the connect group entry.
G-CGRESMDT	CONNECTRESUMEDT	Date (DDMMMYYYY)	The resume date for the connect group entry.
G-INSTDATA	INSTALLATIONDATA	A string	The installation data for this connect or group.

Table 590. Group related fields for CKGRACF LIST (continued)

Field	Verbose	Value	Description
G-LJDATE	LASTCONNECTDATE	A date (DDMMMYYYY)	The date the user has last connected to this group.
G-LJTIME	LASTCONNECTTIME	A time (HH:MM:SS.cc)	The time the user has last connected to this group.
G-NOTRMUAC	NOTERMUACC	Y or N	The NOTERMUAC setting of the user for this group.
G-SUBGRPNM	GROUPNAME	A groupid	The name of a subgroup.
G-SUPGROUP	SUPERIORGROUP	A groupid	The superior group to this group.
G-UACC	UACC	CONNECT, CREATE, JOIN, or USE	The universal group authority.
G-UNVFLG	UNIVERSAL	Y or N	The group is UNIVERSAL.

Table 591. General resource related fields for CKGRACF LIST

Field	Verbose	Value	Description
R-AUDITF	AUDITFAILURE	ALTER, CONTROL, UPDATE, or READ	Global audit FAILURES qualifier.
R-AUDITS	AUDITSUCCESS	ALTER, CONTROL, UPDATE, or READ	Global audit SUCCESS qualifier.
R-DEFDATE	DEFINITIONDATE	A date (DDMMMYYYY)	The date the resource was defined to RACF.
R-INSTDATA	INSTALLATIONDATA	A string	Installation data of the resource.
R-NOTIFY	NOTIFY	A userid	The user to be notified when access violations occur against the resource protected by this profile.
R-AUTHOR	OWNER	A groupid or userid	The owner of the resource.
R-SECLABEL	SECURITYLABEL	A string	The security label of the resource.
R-UACC	UNIVERSALACCESS	ALTER, CONTROL, UPDATE, READ, EXECUTE, or NONE	The universal access authority for the resource.
R-WARNING	WARNING	Y or N	The data set has the WARNING attribute.

Table 592. Data set related fields for CKGRACF LIST

Field	Verbose	Value	Description
D-AUTHOR	OWNER	A groupid or userid	The owner of the data set.
D-UACC	UNIVERSALACCESS	ALTER, CONTROL, UPDATE, READ, EXECUTE, or NONE	The universal access authority for the data set.

Table 593. CKGRACF related fields for CKGRACF LIST

Field	Verbose	Value	Description
C-AUTHORIT	CNGMULTIPLEAUTH	SINGLE, DUAL or TRIPLE	The CKGRACF multiple authority set on this profile.
C-CNGAUTH	CNGINTERNMULTAUT	SINGLE, DUAL or TRIPLE	The internal multiple authority setting for this profile.
C-PWDFLT	CNGPWDEFAULT	A stamp	Stamp to show who set a default password at what time.
Q-ACTION	LASTACTION	One of the queued command actions	The last action performed on this queued command.
Q-CMD	QUEUEDCOMMAND	A string	The actual queued command.
Q-CMDSTMP1	COMMANDSTAMP1	A queued command stamp (See above)	A stamp to show what user did what action.
Q-CMDSTMP2	COMMANDSTAMP2	A queued command stamp (See above)	A stamp to show what user did what action.
Q-CMDSTMP3	COMMANDSTAMP3	A queued command stamp (See above)	A stamp to show what user did what action.
Q-CMDSTMP4	COMMANDSTAMP4	A queued command stamp (See above)	A stamp to show what user did what action.
Q-CMDSTMP5	COMMANDSTAMP5	A queued command stamp (See above)	A stamp to show what user did what action.

For schedule entries in a USER profile, the format of output is slightly different. For every schedule, the *field* name contains the name of the schedule and the identifier is an 'S'. The *verbose* field contains a definition of the contents of the value field. A list of possible combinations follows. A line S-*name* SCHEDULE is a marker for a specific part of a schedule. Any REASON, DELETED or DELREASON *verbose* fields following that line, are associated with that specific part of the schedule.

The I-SCHEDULE SUMMARY lines contain the summarized schedule, considering all schedule entries and their result (See also “USER” on page 1533).

Table 594. Schedule related fields for CKGRACF LIST

Field	Verbose	Value	Description
S-*name*	SCHEDULE	A schedule entry	Gives information about schedule *name*.
S-*name*	REASON	A string	Gives the reason for schedule *name*.
S-*name*	DELETED	A time stamp	The current part of schedule *name* has been deleted.
S-*name*	DELREASON	A string	Gives the reason for DELETED.
I-SCHEDULE	SUMMARY	A string	Summarizes all schedules and their effects.

PWCONVERT

The PWCONVERT command converts a password of a user that was encrypted using the masking algorithm to the installation's encryption method (presumably DES). This can be used as one of the final steps in the elimination of masked passwords.

The PWCONVERT command works in the following manner:

- The user's password is decrypted using the masking algorithm. This always succeeds. For a password encrypted with the masking algorithm, the correct password is found. For passwords encrypted with another method (e.g. DES), an incorrect, nonsense, password is found.
- If the decrypted password seems likely (for example, it can be entered from a keyboard), it is encrypted using the installation's encryption method, and it is saved. Otherwise, the conversion fails.

The PWCONVERT command can be used to limit the duration of a password migration period, when the installation is using the password migration option of the RACF password-encryption exit ICHDEX01 or ICHDEX11. If this option is used, passwords are encrypted and verified using both DES and masking encryption. The migration period should be limited to a short period of time, since it introduces the remote possibility of a *false positive*: a password encrypted using DES that is also the result of a different password encrypted using the masking algorithm. This different password could also be used to logon. In the case of a false positive, the PWCONVERT command gives a wrong result, since it converts the different (wrong) password to the new encryption method.

The PWCONVERT command has the following syntax:

```
PWCONVERT userid [ REASON(reason) ]
userid    Any valid RACF userid.
reason    A reason (See also "Reason keywords in CKGRACF" on page 1501)
```

Userids that have passwords encrypted using the masking algorithm can be detected with the PWHASHED field in the Security zSecure `RACF NEWLIST`. The CARLa script CKRLPWHC can be used to detect all userids with hashed passwords and generate CKGRACF commands to convert the passwords. Note that the PWHASHED field is subject to the same chance of a mistake as the PWCONVERT command.

The PWCONVERT command requires access to the command profile shown in the following table.

Table 595. Command access checks for CKGRACF PWCONVERT

Resource name checked	Access required
CKG.CMD.PWCONVERT	UPDATE

In addition, the command user must have system-wide SPECIAL authority. The PWCONVERT command is not subject to scope checks.

QUESTION

The QUESTION command can be used to set, delete, or verify question/answer pairs, and to list questions present in a user profile.

The QUESTION command has the following syntax:

```
QUESTION profile [ REASON(reason) ] SET qid question PASSWORD(answer) ...
QUESTION profile [ REASON(reason) ] VERIFY qid PASSWORD(answer) ...
QUESTION profile [ REASON(reason) ] LIST [ qid ] ...
QUESTION profile [ REASON(reason) ] DELETE [ qid ] ...

profile           Any valid RACF profile in the USER class
qid               A question identifier, which has syntax Qnn where nn
                  is a nonnegative integer below 100. A question identifier
                  provides an index to a single question/answer pair.
reason            A reason string ("Reason keywords in CKGRACF" on page 1501)
```

Each *question* and *answer* value must be specified as a string (where quotes and conversions are allowed). The *action* (SET, VERIFY, LIST, or DELETE) determines the number of question identifiers that can be specified. The next table presents the details.

Table 596. Actions for CKGRACF QUESTION

Action	Number	Effect	Example
DELETE	none	Deletes all previous question/answer pairs, if present.	DELETE
DELETE	one or more	For each *qid*, deletes the previous question/answer pair identified by *qid*, if present.	DELETE *qid*
LIST	none	Lists all previous question/answer pairs, if present.	LIST
LIST	one or more	For each *qid*, lists the previous question/answer pair identified by *qid*, if present.	LIST *qid*
SET	one or more	For each *qid*, deletes the previous question/answer pair identified by *qid*, if present; then adds a question/answer pair identified by *qid*	SET *qid question* PASSWORD(*answer*)
VERIFY	one or more	For each *qid*, verifies whether the current answer matches with the previous answer identified by *qid*.	VERIFY *qid* PASSWORD(*answer*)

More than one question identifier (+ question + answer) can be specified in a single QUESTION command; the same action is applied to each identifier (+ question + answer) in turn. The target profile is not changed if an error occurs within a single QUESTION command.

The QUESTION command requires access to the command profile shown in the following table.

Table 597. Command access checks for CKGRACF QUESTION

Resource name checked	Access required
CKG.CMD.QUESTION	READ for the LIST and VERIFY actions; UPDATE for the SET and DELETE actions.

In addition, the target user must be within the userdata-scope of the command user (see "CKGRACF authority checks" on page 1559). In the following table, each *nn* is a two-digit number corresponding with question identifier Q*nn*.

Table 598. USRDATA access checks for CKGRACF QUESTION

Resource name checked	Access required
CKG.USRDATA.OWN.USER.CNGC2H*nn*	READ for the LIST and VERIFY actions; UPDATE for the SET and DELETE actions.
CKG.USRDATA.ALL.USER.CNGC2H*nn*	READ for the LIST and VERIFY actions; UPDATE for the SET and DELETE actions.
CKG.USRDATA.SCP.USER.CNGC2H*nn*	READ for the LIST and VERIFY actions; UPDATE for the SET and DELETE actions.

If access to CKG.USRDATA.SCP.USER.CNGC2H*nn* is defined, the following profiles will be checked:

Table 599. Scope access checks for CKGRACF QUESTION

Resource name checked	Access required
CKG.SCP.ID.*userid.owner.dfltgrp*	READ for the LIST and VERIFY actions; UPDATE for the SET and DELETE actions.
CKG.SCP.ID.*groupid.owner*	READ for the LIST and VERIFY actions; UPDATE for the SET and DELETE actions.
CKG.SCP.G.*groups...*	READ for the LIST and VERIFY actions; UPDATE for the SET and DELETE actions.
CKG.SCP.U.*user.groups...*	READ for the LIST and VERIFY actions; UPDATE for the SET and DELETE actions.

Restrictions

A QUESTION command accesses the USR field of a user profile. There are several restrictions on the use of the USR field and the QUESTION command:

- The Security zSecure RECREATE command does not recreate the full USR field. It recreates the multiple-authority setting and installation-defined entries.
- The Security zSecure COPY command does not copy USR fields.

Representation of question/answer pairs

A question/answer pair is represented as an entry in the USR field of a user profile. The USRNM field of the entry is of the form CNGC2H*nn* where *nn* is a two-digit number corresponding with the question identifier Q*nn* of the question/answer pair. The *data* of the USR field entry (for example, the value of the USRDATA field of the entry) consists of a question and a hashed answer. The answer is hashed in such a way that it is very difficult to find another answer with the same hash. The value of the corresponding USRFLG field indicates which hash method has been used. A value of 0 indicates a 16 byte MD5 hash of the concatenation of the answer and the userid.

RDELETE

The RDELETE command can be used to delete any RACF data set, general profile, user profile, or group profile. This can be used for the following purposes:

- Delete fully-qualified generics in general resource classes
- Delete profiles that contain lowercase characters
- Delete data set profiles with the name of a temporary data set, e.g. SYS88308....
- Delete discrete profiles that contain generic characters
- Delete profiles of a group with a zero superior group field.

The RDELETE command cannot be used to delete CONNECT profiles.

The RDELETE command has the following syntax:

```
RDELETE class profile [ type ] [ volser ] [ REASON(reason) ]
class     Any RACF class except CONNECT.
profile   Any profile name; see below.
type      An optional profile type; see below.
volser    An optional volume serial.
reason    A reason (See also "Reason keywords in CKGRACF" on page 1501)
```

The profile can be specified with profile conversion characters (See also “Profile conversion in CKGRACF” on page 1500).

The profile *type* can be one of the following:

Table 600. Profile types for CKGRACF RDELETE

Type	Meaning
ASIS	Profile is as-is
DISCRETE	Profile is discrete
GENERIC	Profile is generic

If no profile type has been specified, and the conversion characters 'C' or 'D' have been used, the conversion characters are used. If neither has been used, the default is ASIS. If both are used, an error message is issued.

If you are generating the CKGRACF to delete the offending profiles with e.g., a CARLa RACF NEWLISTRACF query that selects them, we recommend that you use the field HEXKEY to print the profile name in hexadecimal with the profile conversion character X.

Note: For USER, GROUP, and DATASET profiles, the full name must be specified. Unquoted data set profiles are *not* prefixed with the user's TSO prefix.

Also note that connections to or from users and groups are not deleted when a user or group profile is deleted with RDELETE.

The RDELETE command requires access to the command profile shown in the table below:

Table 601. Command access checks for CKGRACF RDELETE

Resource name checked	Access required
CKG.CMD.RDELETE	UPDATE

In addition, the command user must have system-wide SPECIAL authority. The RDELETE command is not subject to scope checks.

Example - delete a discrete profile with generic characters

For example, assume you have created profile SYS* in class FACILITY, while generic processing was disabled. A discrete profile was created. Now, generic processing is enabled, and you want to delete the profile without disturbing the system in its operation. You can delete the profile with the following command:

```
CKGRACF RDELETE FACILITY 'SYS*' DISCRETE
or
CKGRACF RDELETE FACILITY 'SYS*'D
```

Example - delete a profile with nonprintables, via CARLa

A good way to get rid of *funny* profiles, especially when they contain non-printables, is to use a CARLa query. The recommended approach is as follows.

1. Use the following query (from the ISPF interface, e.g., option **CO.C**, is easiest) with a rough selection that includes the offending profile and displays the DB and RBA fields, which together uniquely identify a specific profile/segment within the database.

   ```
   n t='Select the problem profile in the RACF DB',
     name=SELPROF
     x not(segment=base)
     <step 1): insert rough select statement here>
     <step 2): replace rough select by precise select on DB/RBA>
     sortlist db rba class segment key(44 wrap),
              proftype volume hexkey(0 wrap)
   ```

2. Replace the rough selection with a selection for only the offending profile. We recommend using the DB and RBA values of the offending profile.
3. Add the following (chained) NEWLIST to generate a CKGRACF RDELETE command to CKRCMD.

   ```
   n t='Generate CKGRACF RDEL with the exact HEX key of the profile',
     dd=ckrcmd nopage
     select LISTLIKE=SELPROF
     sortlist "ckgracf rdel" class(0) "'" | hexkey(0) | "'X",
            / "/*  " proftype volume key(44 wrap) "*/"
   ```

4. Verify that the only the offending profile has been selected now. Run the generated CKGRACF RDELETE command.

Note: If you ran the query from the ISPF interface, you can press <PF3> after verification and then use 'R' before CKRCMD in the RESULTS panel to run the generated CKGRACF RDELETE command (because of dd=ckrcmd).

REFRESH

The REFRESH command can be used to update a user profile's revoke/resume settings and to execute or expire queued commands. As a result of a REFRESH command, the user's revoke status and revoke and resume dates can be changed as a scheduled revoke/resume setting is applied. (Note that the USER SCHEDULE and USER RESUME commands immediately apply any changes required; a REFRESH is needed to apply *delayed* settings at the appropriate date.)

The REFRESH command has the following syntax:

```
REFRESH class profile [ REASON(reason) ]

class      Any valid RACF class
profile    Any valid RACF profile
reason     A reason (See also "Reason keywords in CKGRACF" on page 1501)
```

The REFRESH command requires access to the command profile shown in the following table.

Table 602. Command access checks for CKGRACF REFRESH

Resource name checked	Access required
CKG.CMD.REFRESH	UPDATE

The REFRESH command is not subject to scope checks.

The need for a refresh

The following types of CKGRACF commands require a RACF action to be carried out at a future date:

- Queued commands that expire or must be deleted
- Scheduled revoke/resume settings that must be replaced
- Pending commands that need to be executed

Since CKGRACF does not alter the operation of RACF, these actions do not occur of themselves. Instead, CKGRACF must be called with the REFRESH command to perform the relevant actions. When CKGRACF is called to REFRESH a profile, the following actions are performed:

- Queued commands that have expired are marked 'expired'.
- Expired or completed queued commands that have been kept beyond the auditing period are deleted.
- If the resume date of a scheduled revoke or resume setting has passed, and a future set of revoke and resume dates has been scheduled, the revoke and resume date are replaced.
- Inactive scheduled revoke and resume actions that have been kept beyond the auditing period are deleted from the schedule.
- Pending commands are executed and reversed if needed. A pending command will be executed if the planned date for execution is today or already past, and the command still falls within the time period determined by the AT and UNTIL/FOR/LEN keywords.

If a REFRESH is not performed, the following effects occur:

- An expired queued command that has not been marked 'expired' is expired if a user performs any action on the queued command. The queued command cannot be approved, denied, or held.
- If the resume date of a revoke/resume period has passed since the last REFRESH command, and a future revoke/resume period has been scheduled, these future settings are not applied. As a result, the current revoke/resume period is maintained. If a REFRESH is late by one or two days, but occurs at any time between the end of one revoke/resume period and the start of another, the next scheduled revoke/resume dates will be applied properly. Only if no REFRESH is performed at all until after the next revoke/resume date, the user will not have been revoked or resumed in time.
- Queued commands and scheduled revoke/resume settings that have been kept beyond the auditing period are not deleted until the next refresh.
- A pending command is not executed. It will either expire in case of a temporary command (A command that only needs to be 'active' for a certain time), or it will be executed belatedly at the first refresh (which can be very undesirable)

The Security zSecure query CKGXREFR has been provided to determine the user profiles that require a REFRESH. You are advised to run this query as part of a daily job. The query generates the required CKGRACF REFRESH commands. If the daily job is not executed or fails for some reason, the next query can result in delayed REFRESH commands being generated; in the interim period, the effects noted in preceding paragraphs can occur. It is advisable to run the refresh job early each day, to ensure the timely execution of queued commands.

Example: Refreshing a timed command: On the 12th of January, the following command is given:
CKGRACF CMD AT 20JAN2003 FOR 1 PE MY.** ID(HER) ACCESS(READ)

The daily refresh job runs each night just after midnight. The refresh at 20JAN2003 (at for example one minute past midnight) will grant READ access to HER, through the execution of PE MY.** ID(HER) ACCESS(READ). The refresh at 21JAN2003 will restore the situation of 20JAN2003. (For example by issuing PE MY.** ID(HER) DELETE or PE MY.** ID(HER) ACCESS(UPDATE) depending on whether HER already had access and if so, what level.)

If in this example, the 20JAN2003 refresh run is not executed, this user will not get access to MY.** and the command will be expired at 21JAN2003.

Example

An example of the REFRESH command is taken from a CARLa script that generates REFRESH commands for those profiles that need a refresh (member CKGXREFR in the CARLa library).

```
newlist name=REFRGEN  f=CKGOUT nopage title='Refresh generic profiles'
select ckgrefresh<today generic
sortlist "refresh" class "'" | key(0) | "'g"
newlist name=REFRREST f=CKGOUT nopage title='Refresh other profiles'
select ckgrefresh<today not(generic)
sortlist "refresh" class "'" | key(0) | "'d"
```

Part of CARLa script CKGXREFR

SHOW

The SHOW command can be used to show the settings configured in the CKRSITE module or to show a user's access to certain resources.

The SHOW command has the following syntax:

```
SHOW option
```

where `option` can contain any of the option values listed in Table 603.

Table 603. Options for CKGRACF SHOW

Option	Meaning
CKRSITE	Show settings configured in the CKRSITE module.
MYACCESS [NOTERM]	Show the access of the issuer of the command to certain profiles.
MYACCESS ID *id* [NOTERM]	Show the access of userid or groupid to certain profiles.
ZAP	This is an alias for CKRSITE.

The SHOW CKRSITE command shows the settings configured in the CKRSITE module. This command is executed immediately during input parsing (most other commands are delayed until all the commands have been parsed successfully). It prints message CKG100I and shows the class used for profile checks, the default authority requirement for the USER command, the command expiration period, and the auditing expiration period.

The SHOW CKRSITE command does not require access to command profiles and is not subject to scope checks.

Both SHOW MYACCESS and SHOW MYACCESS ID *id* report a number of lines of the following form:

```
resource name access level profile name or possibly empty message

resource name     One of the resource names listed below
access level      NONE, READ, UPDATE, CONTROL, or ALTER
profile name      The profile which determines the access to the resource
```

A message "*userid* has been revoked" will be printed instead of a profile name if *userid* has been revoked. In this case, the access level is set to NONE. In some cases, an empty message is printed instead of a profile name. In these cases, the access level is set to NONE and a separate CKG*nnn*I message is printed.

SHOW MYACCESS shows the access the user has through the access list, conditional access list or UACC. It ignores Global Access Table, RACF exits, and default return code as defined in the Class Descriptor Table.

Access to the following command profile related resources will be reported by CKGRACF SHOW MYACCESS [id]:

C2R.SERVER.ADMIN
CKG.CMD.CMD.EX.ADDGROUP
CKG.CMD.CMD.EX.ADDSD
CKG.CMD.CMD.EX.ADDUSER
CKG.CMD.CMD.EX.ALTDSD
CKG.CMD.CMD.EX.ALTGROUP
CKG.CMD.CMD.EX.ALTUSER
CKG.CMD.CMD.EX.CKGRACF
CKG.CMD.CMD.EX.DELDSD
CKG.CMD.CMD.EX.DELGROUP
CKG.CMD.CMD.EX.PERMIT
CKG.CMD.CMD.EX.RACMAP
CKG.CMD.CMD.EX.RALTER
CKG.CMD.CMD.EX.RDEFINE
CKG.CMD.CMD.EX.RDELETE
CKG.CMD.CMD.EX.SETROPTS
CKG.CMD.CMD.REQ.CONNECT
CKG.CMD.CMD.REQ.PERMIT
CKG.CMD.CMD.REQ.REMOVE
CKG.CMD.LIST
CKG.CMD.USER.REQ.INTERVAL
CKG.CMD.USER.REQ.NOINTERVAL
CKG.CMD.USER.REQ.PWDEFAULT
CKG.CMD.USER.REQ.PWNOEXIT
CKG.CMD.USER.REQ.PWNOHIST
CKG.CMD.USER.REQ.PWNORULE
CKG.CMD.USER.REQ.PWRESET

CKG.CMD.USER.REQ.PWSET
CKG.CMD.USER.REQ.PWSET.*
CKG.CMD.USER.REQ.PWSET.PASSWORD
CKG.CMD.USER.REQ.PWSET.PROMPT
CKG.CMD.USER.REQ.PWSET.DEFAULT
CKG.CMD.USER.REQ.PWSET.PREVIOUS
CKG.CMD.USER.REQ.PWSET.NOPASSWD
CKG.CMD.USER.REQ.PWSET.CURRENT
CKG.CMD.USER.REQ.PWSET.EXPIRED
CKG.CMD.USER.REQ.PWSET.NONEXP
CKG.CMD.USER.REQ.RESUME
CKG.CMD.USER.REQ.SCHEDULE
CKG.RAC.SCP.CONNECT.BASE.SPECIAL
CKG.RAC.SCP.CONNECT.BASE.OPERATIO
CKG.RAC.SCP.CONNECT.BASE.AUDITOR
CKG.RAC.SCP.CONNECT.BASE.OWNER
CKG.RAC.SCP.CONNECT.BASE.RESUME
CKG.RAC.SCP.CONNECT.BASE.REVOKE
CKG.RAC.SCP.CONNECT.BASE.AUTH.USE
CKG.RAC.SCP.CONNECT.BASE.AUTH.CREATE
CKG.RAC.SCP.CONNECT.BASE.AUTH.JOIN
CKG.RAC.SCP.CONNECT.BASE.AUTH.CONN
CKG.RAC.ALL.CONNECT.BASE.SPECIAL
CKG.RAC.ALL.CONNECT.BASE.OPERATIO
CKG.RAC.ALL.CONNECT.BASE.AUDITOR
CKG.RAC.ALL.CONNECT.BASE.OWNER
CKG.RAC.ALL.CONNECT.BASE.RESUME
CKG.RAC.ALL.CONNECT.BASE.REVOKE
CKG.RAC.ALL.CONNECT.BASE.AUTH.USE
CKG.RAC.ALL.CONNECT.BASE.AUTH.CREATE
CKG.RAC.ALL.CONNECT.BASE.AUTH.JOIN
CKG.RAC.ALL.CONNECT.BASE.AUTH.CONN

Additionally, access to discrete profiles of the form CKG.SCHEDULE.*name*, of the form CKG.CMD.CKGAUTH.*name*, or starting with CKG.UCAT. will be reported. For each such profile in the database, there will be one corresponding line in the report. Generic schedule profiles are not reported.

The SHOW MYACCESS command (without ID id) requires access to the following command profile.

Table 604. Command access checks for CKGRACF SHOW MYACCESS

Resource name checked	Access required
CKG.CMD.SHOW.MYACCESS	READ

The SHOW MYACCESS ID *id* command requires access to the following command profiles.

Table 605. Command access checks for CKGRACF SHOW MYACCESS ID id

Resource name checked	Access required
CKG.CMD.ACCESS.ALL	READ
CKG.CMD.SHOW.MYACCESS	READ

When SHOW MYACCESS [ID *id*] is followed by the NOTERM option, the output is not sent to SYSTERM.

Example - SHOW CKRSITE

```
CKGRACF SHOW CKRSITE
CKG100I 00 Contents of CKRSITE module:
           Class:              XFACILIT
           Authority:          SINGLE
           Command expiration: 7
           Audit expiration:   30
```

The meaning of the options listed is:

- The class checked for CKGRACF profiles is XFACILIT. Thus, when the manual refers to 'command resource name CKG.CMD.REFRESH', the XFACILIT class is checked for a profile matching that resource name.
- The default multiple-authority setting is SINGLE. This means that any user that does not have a multiple-authority requirement of his own is subject to single authority. Other options are DUAL and TRIPLE.
- The command expiration time is 7 days. This means that a queued command must be acted upon within 7 days of the previous action. After 7 days, the queued command expires and can no longer be executed.
- The audit expiration time is 30 days. This means that completed or expired commands, and scheduled actions which are wiped or which are not effective anymore will be deleted after 30 days. Until that time, the completed commands and wiped scheduled actions can be displayed using the LIST USER command.

Verify that these options are the same in the Security zSecure program. The Security zSecure command SHOW CKRSITE can be used to display those settings.

SUPPRESS

The SUPPRESS command can be used to suppress messages by number. The command has a global scope and applies to all commands.

The command has the following parameters:

MESSAGE= list
MSG=*list*

A single message number or a list of message numbers enclosed in parentheses. Specifying number *nnn* suppresses message CKG*nnn*I;*nnn* must be in the range 0 to 999. Besides suppressing the messages, this parameter also suppresses processing of the return code associated with the message. Therefore, most serious error messages are not suppressed. Use this option to suppress messages inherent to your configuration that you know about but do not want to clutter your output with on each run.

The SUPPRESS command does not require access to command profiles and is not subject to scope checks.

Example - suppress messages

The following example shows how to suppress error messages you have seen often enough. The example assumes you want to suppress CKG272I and CKG273I.

```
SUPPRESS MSG=(272,273)
```

USER

The USER command can be used for central and decentral user maintenance. It is subject to the multiple-authority settings as well as revoke and resume actions use schedules. Both multiple-authority settings and schedules are explained in this section.

The USER command has the following syntax:

```
USER userid subcommand ...  [ action ] [ REASON(reason) ]
     userid Any valid RACF userid.
 subcommand A USER subcommand; see below; one or more different
            subcommands may be specified.
 action     A queued-command action; see below; the default, REQUEST,
            performs the command for a single-authority userid.
 reason     A reason string (See "Reason keywords in CKGRACF" on page 1501).
```

Specifying USER subcommands

A single USER command can include multiple subcommands. Some subcommands are mutually exclusive. If an error occurs in any of the subcommands when the USER command is processed, the target profile is not changed.

The following *subcommands* can be specified.

- INTERVAL(*value*)
- NOINTERVAL
- PWDEFAULT [*password-option*]
- PWNOEXIT
- PWNOHIST
- PWNORULE
- PWRESET
- PWSET [*password-option*] [*expired-option*]
- RACLINK UNDEF[(*node.id*)]
- RESUME
- SCHEDULE*scheduleaction* [*date*] [*reason*]

See “USER subcommands” on page 1536 for more information about each subcommand.

Specifying Queued-command actions

The USER command requires access to a command profile that includes both an *action qualifier* and the command option. The basic format of the resource name checked is CKG.CMD.USER.*action.option.*. You can specify the following values for action.option:

- ASK for ASK
- REQ for REQUEST
- WITHDRAW
- SEC for SECOND
- CMP for COMPLETE.

If no queued-command action is specified, REQUEST is used. If SECOND or COMPLETE is specified without further qualification, APPROVE is used.

When a queued command is re-entered for a stage following REQUEST, the following processing occurs:

- The PROMPT option does not prompt again.
- The password specified with the PASSWORD option is ignored.
- The REASON keyword is ignored.

The following *queued-command actions* can be specified for CKGRACF USER. See Actions on queued commands for information on these actions.

ASK
REQUEST
SECOND APPROVE
SECOND DENY
SECOND HOLD
COMPLETEAPPROVE
COMPLETE
COMPLETE DENY
COMPLETE HOLD
WITHDRAW

Access checking

The type of access checking done for a USER command depends on the options specified on the command. See the following topics for more information.

- "Access checks for options of CKGRACF USER PWSET"
- "Scope access checks for CKGRACF USER" on page 1536
- "Schedule access checks for CKGRACF USER SCHEDULE" on page 1536

Access checks for options of CKGRACF USER PWSET: The PWSET option can also have several sub-options. For backwards compatibility, the PWSET option alone includes all sub-options in the command profile check. Therefore, for profile checking, the CKG.CMD.USER.*action.*PWSET command is effectively the same as the CKG.CMD.USER.*action.*PWSET.* command for checking.

A full list of checks is shown in the following table.

Table 606. Command access checks for options of CKGRACF USER PWSET

USER PWSET Option	Actions	Resource name checked	Access required
INTERVAL	ASK REQUEST or WITHDRAW SECOND COMPLETE	CKG.CMD.USER.ASK.INTERVAL CKG.CMD.USER.REQ.INTERVAL CKG.CMD.USER.SEC.INTERVAL CKG.CMD.USER.SEC.INTERVAL CKG.CMD.USER.CMP.INTERVAL	UPDATE
NOINTERVAL	ASK REQUEST or WITHDRAW SECOND COMPLETE	CKG.CMD.USER.ASK.NOINTERVAL CKG.CMD.USER.REQ.NOINTERVAL CKG.CMD.USER.SEC.NOINTERVAL CKG.CMD.USER.CMP.NOINTERVAL	UPDATE

Table 606. Command access checks for options of CKGRACF USER PWSET (continued)

USER PWSET Option	Actions	Resource name checked	Access required
PWDEFAULT	ASK REQUEST or WITHDRAW SECOND COMPLETE	CKG.CMD.USER.ASK.PWDEFAULT CKG.CMD.USER.REQ.PWDEFAULT CKG.CMD.USER.SEC.PWDEFAULT CKG.CMD.USER.CMP.PWDEFAULT	UPDATE
PWNOEXIT	ASK REQUEST or WITHDRAW SECOND COMPLETE	CKG.CMD.USER.ASK.PWNOEXIT CKG.CMD.USER.REQ.PWNOEXIT CKG.CMD.USER.SEC.PWNOEXIT CKG.CMD.USER.CMP.PWNOEXIT	UPDATE
PWNOHIST	ASK REQUEST or WITHDRAW SECOND COMPLETE	CKG.CMD.USER.ASK.PWNOHIST CKG.CMD.USER.REQ.PWNOHIST CKG.CMD.USER.SEC.PWNOHIST CKG.CMD.USER.CMP.PWNOHIST	UPDATE
PWNORULE	ASK REQUEST or WITHDRAW SECOND COMPLETE	CKG.CMD.USER.ASK.PWNORULE CKG.CMD.USER.REQ.PWNORULE CKG.CMD.USER.SEC.PWNORULE CKG.CMD.USER.CMP.PWNORULE	UPDATE
PWRESET	ASK REQUEST or WITHDRAW SECOND COMPLETE	CKG.CMD.USER.ASK.PWRESET CKG.CMD.USER.REQ.PWRESET CKG.CMD.USER.SEC.PWRESET CKG.CMD.USER.CMP.PWRESET	UPDATE
PWSET	ASK REQUEST or WITHDRAW SECOND COMPLETE	CKG.CMD.USER.ASK.PWSET CKG.CMD.USER.REQ.PWSET CKG.CMD.USER.SEC.PWSET CKG.CMD.USER.CMP.PWSET	UPDATE

RESUME	ASK REQUEST or WITHDRAW SECOND COMPLETE	CKG.CMD.USER.ASK.RESUME CKG.CMD.USER.REQ.RESUME CKG.CMD.USER.SEC.RESUME CKG.CMD.USER.CMP.RESUME	UPDATE
SCHEDULE	ASK REQUEST or WITHDRAW SECOND COMPLETE	CKG.CMD.USER.ASK.SCHEDULE CKG.CMD.USER.REQ.SCHEDULE CKG.CMD.USER.SEC.SCHEDULE CKG.CMD.USER.CMP.SCHEDULE	UPDATE

Scope access checks for CKGRACF USER: In addition to access checking for the USER PWSET options, the target user must be within the scope of the command user. (See CKGRACF authority checks.)

Table 607. Scope access checks for CKGRACF USER

Resource name checked	Access required
CKG.SCP.ID.*userid.owner.dlftgrp*	UPDATE
CKG.SCP.G.*groups...*	UPDATE
CKG.SCP.U.*user.groups...*	UPDATE

Schedule access checks for CKGRACF USER SCHEDULE: For a USER SCHEDULE command, the user must have access to the target schedule:

Table 608. Schedule access checks for CKGRACF USER SCHEDULE

Resource name checked	Access required
CKG.SCHEDULE.*schedule*	UPDATE

USER subcommands

This section describes the subcommands supported by the USER command.

INTERVAL: The INTERVAL subcommand can be used to set the password and password phrase interval for a user. If this value is lower than the system-wide interval setting, then it becomes the effective interval setting. Otherwise, the value

from the system-wide interval setting is used. The user's password and password phrase (if any) are not affected. The INTERVAL subcommand is mutually exclusive with the NOINTERVAL subcommand.

The INTERVAL subcommand has the following syntax:

```
INTERVAL[(value)]
value      A value of at least one and at most the system's INTERVAL value
(due to SETROPTS PASSWORD(INTERVAL), or 254 if no system
INTERVAL value was set).  If value is not specified, the SETROPTS
value will be taken.
```

NOINTERVAL : The NOINTERVAL subcommand can be used to turn off a user's password and password phrase interval so that no password or password phrase change is required. The user's password and password phrase (if any) are not affected. The NOINTERVAL subcommand is mutually exclusive with the INTERVAL subcommand.

The NOINTERVAL subcommand has no parameters It has the following syntax:

```
NOINTERVAL
```

PWDEFAULT: The PWDEFAULT subcommand can be used to set or delete a user's default password. This password is used when the PWRESET or PWSET DEFAULT commands are used. The default password is subject to the password rules, password history, and new-password exit at the time of setting, and is stored in encrypted form.

The PWDEFAULT subcommand has the following syntax:

```
PWDEFAULT [ password-option ]
password-option   Any PWDEFAULT password option; see below.
```

Table 609 list the PWDEFAULT password options.

Table 609. Options for CKGRACF USER PWDEFAULT

Option	Meaning
DELETE	Delete the default password, if present.
PASSWORD*(value)*	Set the default password to *value* (*value* is the password in clear text). The parentheses and the value are optional if the action is not REQUEST.
PROMPT	Prompt and re-prompt for a default password. This option cannot be used in batch mode.

If no password-option is specified, and the program is not in batch mode, PROMPT is used. In batch mode, an error message is issued.

If the target userid is subject to multiple-authority controls, the default password as specified with the REQUEST action is used. For subsequent action, use either the PASSWORD option with a dummy password, or use the PROMPT option. You are not prompted again.

If the default password is set while mixed case password support is inactive, and a password is reset (using CKGRACF) while mixed case password support is active, you might need to enter your password in uppercase to be able to logon.

If the USER PWDEFAULT and either the USER PWSET or the USER PWRESET subcommands are used in a single USER command, the PWDEFAULT subcommand is executed before the PWSET or PWRESET subcommand.

PWNOEXIT: The PWNOEXIT subcommand can be used to disable the ICHPWX01 exit call from CKGRACF when a password is set with PWSET, for example, and to disable the ICHPWX11 exit call from CKGRACF when a password phrase is set. This subcommand is useless on its own, since it's only valid for the current USER command.

The PWNOEXIT subcommand has no parameters; it has the following syntax:

```
PWNOEXIT
```

PWNOHIST: The PWNOHIST subcommand can be used to disable the history check performed by CKGRACF when a password or password phrase is set with PWSET, for example. This subcommand is useless on its own, since it's only valid for the current USER command.

The PWNOHIST subcommand has no parameters; it has the following syntax:

```
PWNOHIST
```

PWNORULE: The PWNORULE subcommand can be used to disable the password and password phrase rule checking performed by CKGRACF when a password or password phrase is set withPWSET, for example. This subcommand is useless on its own, since it's only valid for the current USER command.

PWRESET: The PWRESET subcommand can be used to set the user's password to the user's default password as set by CKGRACF. Its function is identical to PWSET DEFAULT EXPIRED. This option is provided as a relatively safe option for a helpdesk, while the PWSET option should be restricted.

The PWRESET subcommand has no parameters; it has the following syntax:

```
PWRESET
```

The PWRESET subcommand is mutually exclusive with the PWSET subcommand.

If the target user is subject to multiple-authority controls, the default password at the time of the REQUEST action is used. Changes to the default password while the command is queued do not change the copy of the default password stored with the queued command. If the default password was changed during queueing, warning message CKG646I is to be issued when the command is completed. If no default password can be found, the PWSET subcommand fails; the user is not prompted for a password.

If the default password is set while mixed case password support is inactive, and a password is reset (using CKGRACF) while mixed case password support is active, you might need to enter your password in uppercase to be able to logon.

If the PWDEFAULT and PWRESET subcommands are used in a single USER command, the PWDEFAULT subcommand is executed before the PWRESET subcommand.

PWSET: The PWSET subcommand can be used to set a user's password or password phrase.

It has the following syntax:

```
PWSET password-option expire-option
password-option   Any PWSET password option; see below.
expire-option     Any PWSET expire option; see below.
```

The PWSET subcommand is mutually exclusive with the PWRESET subcommand.

The PWSET password options are:

Table 610. Options for CKGRACF USER PWSET

Option	Meaning
PASSWORD*(value)*	Set the password to *value*, which is the password in clear text. The parentheses and value are optional if the action is not REQUEST.
PHRASE*(value)*	Set the password phrase to *value*, which is the password phrase in clear text, enclosed in single quotes. A single quote in the password phrase must be written as two consecutive single quotes, so a phrase like `th'is'phrase` must be specified as `'th''is''phrase'`. The parentheses and value are optional if the action is not REQUEST.
PROMPT	Prompt and re-prompt for a password. This option cannot be used in batch mode.
DEFAULT	Set the password to the default password.
RANDOM	Set the password to a random string. See section “Creating random passwords” on page 1553.
NOPASSWORD	Sets the status of the userid to protected, so it cannot be used to enter the system by employing a password or password phrase. See section “Protecting a userid with the PWSET NOPASSWORD option” on page 1554.
PREVIOUS	Return to the previous password from the password history. This might not be the actual previous password, for example, if the ALTUSER command has been used or if the current password has been zapped. The current password is added to the password history; thus, repeated use of the PWSET PREVIOUS subcommand alternates between two passwords, and does not travel back through the whole of the password history.
CURRENT	Leaves the password unchanged. This option is intended to be used with expire option EXPIRED or NONEXPIRED to expire or unexpire the current password phrase. The password history and the password phrase history is not read or changed.

If no password option is specified, DEFAULT is used. If no default password can be found, the user is prompted for a password. A new password specified for the PASSWORD or PROMPT options, or a prompted password for the DEFAULT option, is subject to the password rules, the password history, and the new-password exit.

When the default password is set while mixed case password support is inactive, and a password is reset (using CKGRACF) while mixed case password support is active, you might need to enter your password in uppercase to be able to logon.

If the PWDEFAULT and PWSET DEFAULT subcommands are used in a single USER command, the PWDEFAULT subcommand is executed before the PWSET subcommand.

If the target userid is subject to multiple-authority controls, the password or password phrase as read or specified in the REQUEST action is used. For subsequent actions, the PASSWORD option can be used with a dummy password or password phrase, and the PROMPT option does not prompt again. Changes to the default password while a PWSET DEFAULT subcommand is queued do not change the copy of the default password stored with the queued command; similarly, changes to the previous password while a PWSET PREVIOUS subcommand is queued do not change the copy of the previous password stored with the queued command. In both cases, warning message CKG645I or CKG646I is issued when the command is completed.

The PWSET expire options are:

Table 611. Expire options for CKGRACF USER PWSET

Option	Meaning
EXPIRED	Expire the new password or password phrase; it must be changed at the next logon.
NONEXPIRED	Do not expire the new password or password phrase.

If no expire option is specified, EXPIRED is used.

RACLINK UNDEF: Use the `RACLINK UNDEF` subcommand for deleting (undefining) all associations of a user. You can use the `RACLINK UNDEF(`*`node.id`*`)` subcommand for deleting a single association, between the user on the node where the subcommand is executed–the local node–and the user ID on node *node*. This command is designed to remove the one-sided association left when a `TSO RACLINK UNDEF` operation refuses to delete either the reference of *user1* to *user2*, or the reference of *user2* to *user1*.

Unlike the `TSO RACLINK UNDEF` command, the `RACLINK UNDEF(`*`node.id`*`)` subcommand does not remove the reference to the local user from the user profile on the remote node *node*. Indiscriminate use of the `RACLINK UNDEF` subcommand can therefore lead to inconsistencies in user associations.

RESUME: The RESUME subcommand can be used to resume a user. The current revoke/resume schedules for the user (as set by the USER SCHEDULE command) are taken into account; if these determine the user's revoke/resume status, they will be applied. If no scheduled revoke/resume actions are present, or if all scheduled actions apply to future dates, the RESUME subcommand resumes the userid. The RESUME subcommand can be used to override the revoke status as set by the ALTUSER REVOKE command, or due to excessive logon attempts or inactivity.

If the scheduled actions determine that the user should be revoked, the RESUME subcommand sets the userid to revoked status and issues message CKG120I.

In addition to setting the revoke status and the revoke/resume dates, the RESUME subcommand always sets the last-use date and time to midnight (00:00) of today, and sets the revoke count (which counts faulty password and password phrase attempts) to zero. This ensures that, by the time the user is resumed (either now or

when the scheduled resume date is reached), the user is not immediately revoked again because of inactivity or too many failed logons.

If the USER RESUME and USER SCHEDULE subcommands are used in a single USER command, the SCHEDULE subcommand is executed *before* the RESUME subcommand.

The RESUME subcommand has no parameters; it has the following syntax:

```
RESUME
```

SCHEDULE: The SCHEDULE subcommand can be used to maintain revoke and resume *schedules*, for example, to set up and maintain the periods of time during which the user is able to logon. The concept of revoke/revoke schedules is explained in Revoke/resume schedules.

The SCHEDULE subcommand is used to add or delete scheduled revoke and resume actions; this can cause the target user's revoke and resume dates to be changed, and can cause the user to become revoked or resumed.

The SCHEDULE subcommand has the following syntax:

```
SCHEDULE schedule action date [ reason ]
schedule    Name of the schedule; see below.
action      Any SCHEDULE action; see below.
date        Date or period for the SCHEDULE action; see below.
reason      Optional reason for the schedule action; see below.
```

If the USER RESUME and USER SCHEDULE subcommands are used in a single USER command, the SCHEDULE subcommand is executed before the RESUME subcommand.

Schedule *names* are words of up to 8 alphanumerical characters; names are not case-sensitive. The names can be determined by the installation as they see fit, e.g. 'REVOKE' for a schedule limited to system administrators, and 'DECENTRL' for a schedule that decentral administrators use. Access to schedules is restricted using *schedule* profiles, see Schedule profiles. Different schedule names have no priority over each other. Decentral administrators that have different scopes can safely be granted access to the same schedule names: each decentral administrator is able to apply the schedule only within his own scope.

The SCHEDULE actions are:

Table 612. Actions for CKGRACF USER SCHEDULE

Action	Meaning
ENABLE	Enable (for example, resume) the user from the date specified or for the period specified. A user will only be resumed if all schedules agree. If a period is specified, the user will be revoked after the period ends.
DISABLE	Disable (for example, revoke) the user from the date specified or for the period specified. A user will be revoked if revoked on *any* schedule. If a period is specified, the user will be resumed after the period ends, unless another schedule determines the user should be revoked.

Table 612. Actions for CKGRACF USER SCHEDULE (continued)

Action	Meaning
WIPE	Delete the action from the schedule, either one action if one date is specified or all actions for a period if a range is specified.

If an action changes the overall effect of the schedules, the user's revoke status and revoke and resume dates are changed.

With the SCHEDULE subcommand and the ENABLE or DISABLE action, either a single date or a single period can be specified in the following manner:

Table 613. Date formats for CKGRACF USER SCHEDULE

Option	Meaning
START-DATE	Enable or disable the user from the date specified. The effect of the action is indefinite. All actions scheduled for START-DATE and later dates within the schedule are wiped. For example, `SCHEDULE HARD DISABLE TODAY` would revoke the user as of today.
(START-DATE:END-DATE)	Perform the action from the start-date to the end-date. Both dates are included in the period. For example, `ENABLE(01OCT1998:01NOV1998)` enables from Oct 1 up to and *including* Nov 1). Any previously scheduled actions covering this period are wiped, scheduled actions outside of this period are not affected.
(START-DATE,LENGTH)	Perform the action from the start-date for the number of days specified by LENGTH. For example, `ENABLE (01OCT1998,2)` enables the user from Oct 1 up to and including Oct 2, but not including Oct 3. The length must be in the range 1 to 500. Any previously scheduled actions covering this period are wiped, scheduled actions outside of this period are not affected.

Notes:

1. The parentheses are not required.
2. With a REQUEST or ASK, the start-date must be today or a future date.
3. A date has the format `01OCT1998` or (Julian date) `1998/274` , or the literal value TODAY.
4. Wiped schedules remain in the profile as part of the audit trail for an additional period. Only after the audit period has passed they will be physically wiped from the profile.

With the SCHEDULE subcommand and the WIPE action, either a single date or a single period can be specified in the following manner:

Table 614. Date formats for CKGRACF USER SCHEDULE WIPE

Option	Meaning
START-DATE	For the schedule indicated, wipe the action set for that date.
(START-DATE:END-DATE)	For the schedule indicated, wipe all actions for the period specified. The start and end dates are included in the period. For example, the command `WIPE (01OCT1998:01NOV1998)` wipes scheduled actions from Oct 1 up to and *including* Nov 1.

Table 614. Date formats for CKGRACF USER SCHEDULE WIPE (continued)

Option	Meaning
(START-DATE,LENGTH)	For the schedule indicated, wipe all actions from the start-date for the number of days specified by LENGTH. For example, the command `WIPE (01OCT1998,2)` wipes scheduled actions from Oct 1 up to and including Oct 2, but not including Oct 3. The length must be in the range 1 to 500.

See Revoke/resume schedules for an explanation and examples of schedules.

REASON: The optional *reason* string is stored with the scheduled revoke/resume settings or with the command as a whole when there is no SCHEDULE subcommand defined. The string is used to add an explanation or reason for the action.

It is specified in the following manner:

```
REASON(reason)
reason      A reason string (See also Reason keywords in CKGRACF)
```

If the target userid is subject to multiple-authority, the reason specified with the REQUEST action is used; for later actions, any reason specified is ignored.

Note: If a non-restructured database is used and the command is queued because the target userid is subject to multiple-authority, the reason string might not fit into the USR entry used to store the queued command. In that case, the reason is truncated and message CKG627I is issued.

Revoke/resume schedules

CKGRACF provides a revoke and resume schedule facility that permits different decentralized administrators to set several future revoked or resumed periods. This function is supported for de-centralized administrators that do not have the group-SPECIAL attribute over the affected user profiles. The revoke and resume schedule process works in the following way:

- The installation can define any number of schedules. A schedule is identified by a name of 1 to 8 alphanumerical characters. Update of a schedule is granted through the name of the schedule.
- Each schedule consists of a list of dates, with one action per date. An action can be ENABLE or DISABLE. Within any single schedule, the effect of the schedule on the user depends on the last action only; two DISABLEs followed by a single ENABLE leads to an enabled user.
- All users have their own scheduled actions, and all schedules are independent. The COURSES schedule for PETER does not affect the COURSES schedule for ROB; the VACATIONS schedule for PETER does not affect the COURSES schedule for PETER.
- If multiple schedules are set for a single user–that is, the userid has scheduled actions for more than one schedule name–, the user will be revoked if disabled by *any* schedule. A *hard* revoke can be implemented by creating the schedule REVOKE, granting access to the system administrator only, and then disabling a user on that schedule. Other schedules are not able to resume the user.
- System and decentralized administrators can have access to different schedules. To alter a schedule, the administrator must have: (a) access to the

CKGRACF USER SCHEDULE command; (b) access to the schedule; and (c) the target user must lie within the CKGRACF-defined scope.

- A userid is revoked if revoked by *any* schedule. The userid is only to be resumed if all schedules agree.
- Any schedule can be altered to *enable* the user from a date or for a period of time; the user will be resumed by this schedule until the end of the period, and be revoked afterwards. A schedule can also be altered to *disable* the user from a date or for a period of time; the user will be revoked for at least this period of time, and resumed afterwards, unless he is revoked by any other schedule. Finally, any scheduled setting or all settings during a period of time can be *wiped*. During the period of time for which the scheduled actions were wiped, the userid is subject to the overall result of unwiped previous actions combined with the other schedules.
- During the period of time before the first scheduled action applies, or if no scheduled actions have been set at all, the revoke status of the user is not determined by the schedules. As long as the scheduled actions do not determine the revoke status, the schedules do not override the ALTUSER REVOKE or ALTUSER RESUME command. After any scheduled action has been applied, the schedules determine the user's revoke status, and override the ALTUSER REVOKE or ALTUSER RESUME command.
- The CKGRACF LIST USER command (see "LIST" on page 1515) can be used to display the scheduled actions for a userid, as well as the overall revoke/resume schedule that is the result of combining all scheduled actions.
- The CKGRACF RESUME command will only resume the user if the user is not subject to scheduled actions, or if the scheduled actions for the user allow a resume.
- The CKGRACF REFRESH command should be used to evaluate the schedules of a user, and apply any actions due today. For more information see "REFRESH" on page 1527.

Example: simple definitions: Two group administrators must both be able to specify a holiday schedule for users within their separate groups. There is also a central administrator who is only allowed to administer the 'hard' revoke schedule.

The schedule names defined are HOLIDAY and REVOKE; we assume the scope of the decentral administrators has already been defined. The administrators also need UPDATE access to the USER SCHEDULE command.

```
rdefine xfacilit ckg.schedule.holiday uacc(none)
permit ckg.schedule.holiday class(xfacilit) id(grp1adm grp2adm) +
access(update)
rdefine xfacilit ckg.schedule.revoke uacc(none)
permit ckg.schedule.revoke class(xfacilit) id(centradm) access(update)
```

Example revoke and resume schedules:

- "Creating a simple schedule" on page 1545
- "Revoking and resuming schedules before and after a the schedule applies" on page 1545
- "Using wiping actions" on page 1546
- "Revoking and resuming behavior based on multiple schedules" on page 1546
- "Implementing a hard revoke action" on page 1547
- "Setting up a schedule for selective system access over multiple periods" on page 1548

Creating a simple schedule: The following figure shows the revoke status of user PETER. In January, a single revoke period has been scheduled from August 1 to August 31. On March 1, PETER makes excessive logon attempts, which cause him to be revoked. On March 5, the CKGRACF USER RESUME command is used to resume the user, and the scheduled revoke period in August still applies.

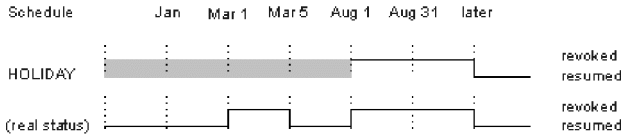

Figure 517. Simple revoke schedule

Note that, before August 1, the revoke status was not determined by the schedules; after August 31, the schedules do determine the revoke status.

The commands to achieve these schedules could have been:

```
CKGRACF USER PETER SCHEDULE HOLIDAY DISABLE (01AUG1998:31AUG1998)
--- excessive failed logons ---
CKGRACF USER PETER RESUME
```

Revoking and resuming schedules before and after a the schedule applies: To illustrate the effect of revoke and resume schedules for the period *before* the schedule first applies and the period after the schedule first applies, see the four figures below. In all cases, the schedules do not determine the revoke status before they first apply, but do determine the revoke status afterwards.

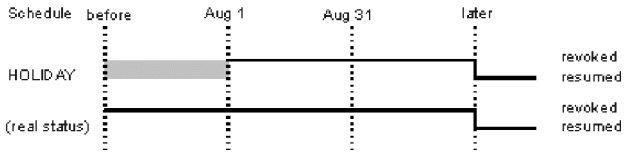

Figure 518. Revoked before schedule, a scheduled disabled period, and resumed afterwards

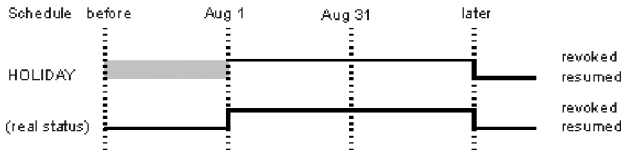

Figure 519. Resumed before schedule, a scheduled disabled period, and resumed afterwards

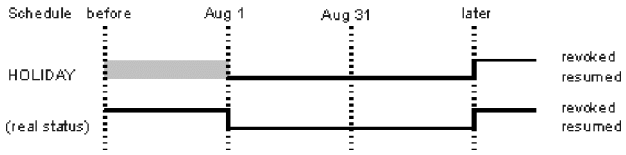

Figure 520. Revoked before schedule, a scheduled enabled period, and revoked afterwards

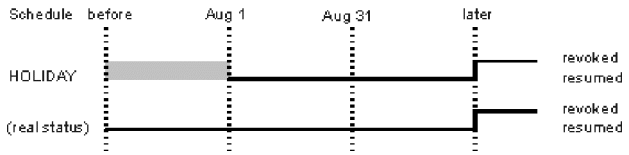

Figure 521. Resumed before schedule, a scheduled enabled period, and revoked afterwards

Using wiping actions: If a user is revoked or resumed due to scheduled actions, his status can be changed by adding another scheduled action. If the user should no longer be subject to a schedule (for example, the schedule HOLS98 is no longer used), the scheduled actions can also be wiped out. You can also use the wipe action if the scheduled actions were applied by mistake or for the wrong period (say, a year early).

If the wiped actions apply to future dates, the revoke status is not changed, and the revoke/resume date can be changed. If, however, the wiped actions apply to past dates or today, wiping the actions can change the user's current revoke status. The following cases can occur:

- After the actions have been wiped, the schedules still determine the user's current revoke status. In this case, message CKG121I or CKG122I is issued. These messages indicate whether the user's revoke status has changed after the wipe, and what the user's revoke status is set to as the result.
- After the actions have been wiped, the schedules do not determine the user's current revoke status. For instance, all scheduled actions were deleted, or all scheduled actions that have been left apply to future dates. In effect, this causes the user's revoke status *from the viewpoint of the schedules* to be undefined (the grey area in the preceding examples). Note that a RESUME command succeeds in resuming the user. In this case, message CKG122I or CKG123I is issued. Message CKG122I indicates that the user's revoke status has not changed after the wipe, and what the user's revoke status is set to. Message CKG123I indicates that the revoke status would have been left to revoked, but that the RESUME subcommand was also used. The user is resumed by the RESUME subcommand.
- You can use the WIPE command (see "WIPE" on page 1558) to remove all traces of a schedule from a profile.

Revoking and resuming behavior based on multiple schedules: This example illustrates revoke and resume behavior based on multiple schedules. This example is based on the following conditions:

- Two schedules have been created called COURSE and VACATION.
- On the VACATION schedule, the userid affected is revoked from January 15 to January 30; resumed on January 31, and revoked again from December 20 to January 1.
- On the COURSE schedule, the userid is revoked from May 1 to May 30 and is resumed on May 31.
-

Figure 522 on page 1547 shows a graph of the individual and combined schedules (overall).

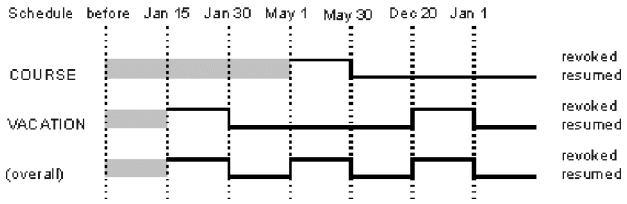

Figure 522. Multiple revoke/resume schedules

The following example shows the commands to create these schedules for userid *PETER*.

```
USER PETER SCHEDULE COURSE DISABLE (01MAY1998:30MAY1998)
USER PETER SCHEDULE VACATION DISABLE (15JAN1998:0JAN1998)
USER PETER SCHEDULE VACATION DISABLE (20DEC1998:01JAN1999)
```

You can use the following LIST command to list the scheduled actions for this user along with the resulting overall schedule: `CKGRACF LIST USER PETER`. See "LIST" on page 1515 for sample output of the LIST command.

Implementing a hard revoke action: This example describes the hard revoke action. The example is based on the following conditions:

- A userid for an external expert was disabled on schedule REVOKE from January 1.
- The same userid is enabled from August 1 for 7 days.
- The userid is finally revoked from August 8.

Based on these conditions, the userid revoke and resume status follows the REVOKE schedules shown in Figure 523.

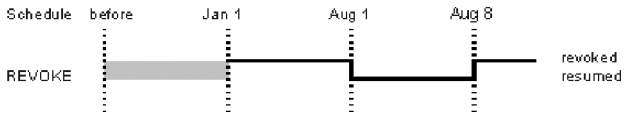

Figure 523. Hard revoke

The following example shows commands to create the REVOKE schedule for the userid *EXTERN*. In this example, the same schedule is used to revoke and resume the userid.

```
USER EXTERN SCHEDULE REVOKE DISABLE 01JAN1998
USER EXTERN SCHEDULE REVOKE ENABLE (01AUG1998,7)
```

If the userid had been configured to revoke on one schedule (REVOKE) and resumed on a different schedule (DECENTRL), the overall effect would have been as follows:

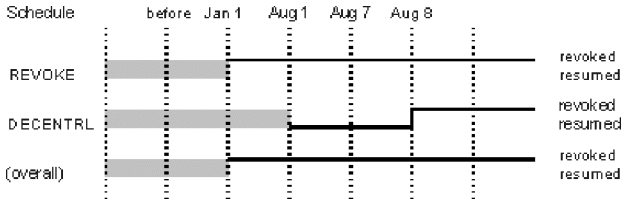

Figure 524. Multiple revokes

The resumed period of the DECENTRL schedule does not resume the user because the REVOKE schedule determines that the user should still be revoked.

The following example shows commands that could have been used to create the separate revoke and resume schedules.

```
USER EXTERN SCHEDULE REVOKE DISABLE 01JAN1998
USER EXTERN SCHEDULE DECENTRL ENABLE (01AUG1998,7)
```

Setting up a schedule for selective system access over multiple periods: This example describes selective system access. The scenario for this example is based on the following conditions:

- A userid for an external expert is created with status revoked.
- The external expert is to work on two projects, DB2 and CICS, and receives the following schedule for permits to the required data sets:
  - Enabled for DB2 and CICS from January 1 to May 1.
  - Enabled for CICS from August 1 to August 7
  - Enabled from August 10 to August 15.

Based on these conditions, the userid revoke and resume status follows the schedule shown in Figure 525, which will probably lead to an unexpected result.

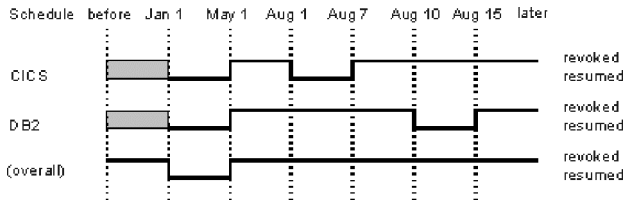

Figure 525. Multiple enabled periods

The reason for the unexpected result is that, if a user is enabled for a period, he is revoked afterwards. In this case, the resumed periods in August do not overlap, so the user remains revoked. The rationale is that the external expert should not be able to use his permits on DB2 data sets a week early.

If the user really needed to be resumed on both projects in August, the CICS and DB2 administrators need to work together.

- If the CICS project is over, the scheduled actions for the CICS profile should be wiped.
- If the user should be enabled for both projects, both administrators should agree, and both should enable him.
- If the user is going to work on one project one week, and another project another week, perhaps two different userids are required.

For the problem described in preceding paragraphs, revoke or resume schedules are not the solution. In this case, you should use temporary permits or connects.

Setting up multiple authority

CKGRACF provides for *multiple authority* to aid in the separation of powers. If a profile is subject to multiple-authority controls, any CKGRACF USER or CKGRACF CMD command for that profile must be validated by either one or two

other users before it is executed. This makes it possible to protect sensitive profiles from unauthorized alteration. The CKGRACF multiple-authority system functions in the following manner:

- Any profile can have a multiple-authority requirement, which is stored in the profile's USR field. If no requirement is stored in the profile, the installation-defined system-wide default is used. Setting a system-wide default enables the installation to define a multiple-authority requirement for all profiles that do not, or can not have a multiple-authority requirement set on them; This also defines the default multiple-authority requirement for all new profiles.
- The multiple-authority requirement affects the operation of the USER and CMD commands. Other commands are not subject to multiple-authority.
- The multiple-authority requirement for a profile is either SINGLE, DUAL or TRIPLE.
- There are two different actions you can use to initialize a command; The ASK and REQUEST actions. The ASK action is basically the same as the REQUEST action, with the exception that a REQUESTed command can be executed at once if the target profile has a SINGLE multiple-authority requirement, whereas an ASKed command will always be queued for later approval. This effectively entails that an ASKed command on a SINGLE multiple-authority profile will go through the same steps as a REQUESTed command for a DUAL multiple-authority profile.
- The multiple-authority requirement is either SINGLE, DUAL, or TRIPLE. Commands for single-authority profiles only need to be ratified or reviewed by one person with the authority to approve a command. Commands for dual-authority profiles need to be ratified or reviewed by two users with authority, while commands for triple-authority profiles need to be ratified or reviewed by three different users with authority. [23]
- A single profile's multiple authority requirement is set using the AUTHORITY command (see “AUTHORITY” on page 1503). Any profile without a multiple-authority requirement is subject to the default, which can be listed using the `SHOW CKRSITE` command (see “SHOW” on page 1529).
- If a command is issued for a profile which requires multiple-authority (for example, the requirement is not SINGLE) or the action is ASK, the command is *queued*. A queue of commands is stored in the profile's USR field. Subsequent CKGRACF commands can be issued to ratify or deny a queued command, as explained in the following text. Queued commands *expire* after an installation-defined period, or when they are not completed at the time they should have been executed (if AT is defined on the CMD command); expired commands can no longer be executed. After a command is completed (e.g. denied, executed, or expired), it is kept in the user profile until an *auditing period* has passed; after that period has expired, the command is deleted from the queue. All queued commands can be listed using the CKGRACF LIST command. The expiration period and auditing period can be listed using the SHOW CKRSITE command.
- Queued commands pass various *stages*, depending on the target profile's multiple-authority requirement. Commands for a dual-authority profile are requested, then completed; commands for a triple-authority profile are requested, seconded, and then completed. In each stage, actions must be performed by a userid different from the previous stages. The next section describes the possible actions and their effects.

23. A *user with authority* is defined as someone that can either REQUEST, SECOND or COMPLETE a command. The ASK command option is not considered an authoritative action.

- Authorization for each queued-command stage is granted separately. A help desk would have access to the REQUEST action, which executes commands for normal, single-authority userids, and queue commands for all other userids. The queued commands would then have to be ratified, and the help desk would not have authority to do this.
- If a group of administrators had access to both the REQUEST and COMPLETE actions, any administrator could request a command, and a colleague would have to ratify the command before it could be executed. This way you can implement a dual-sign administration policy. Another example would be an auditor who has access to the ASK action, not being able to actually execute anything, but able to request an approval, even for SINGLE multiple-authority profiles.

Actions on queued commands

A queued command must be acted on by entering the identical command again with a different queued-command action. Note that the easiest way to perform these actions is to use the Security zSecure ISPF interface to CKGRACF.

Table 615 lists the actions that can be performed on a queued command and describes the effect of the action.

Table 615. Actions on queued commands

Action	Effect
APPROVE	The command is approved and is either executed or passed to another person in order to be okayed.
HOLD	A decision is not made yet; expiration of the command is delayed. (Expiration counts from the last action. By repeatedly HOLDing a command, expiration can be delayed for a long time.)
DENY	The command is denied and can no longer be executed.
WITHDRAW	The command is withdrawn and can no longer be executed.

These actions are subject to the following rules:

- A command can only be approved, held, denied, or withdrawn if it still could be completed. After a command has been expired, denied, withdrawn, or executed, no further actions are possible.
- The WITHDRAW action can be performed by anyone with the authority to request the command. It is intended for use by the requesting user, in case a mistake has been made. A WITHDRAW action is allowed at any time until the command has been completed. After the command has been completed, a request must be made for the opposite action to 'undo' the command.
- The HOLD, DENY, or APPROVE actions must be used with SECOND or COMPLETE on queued commands. A command for a triple-authority userid passes from the SECOND to the COMPLETE stage by a SECOND APPROVE command. After the command has moved to the next stage, the seconding user can no longer deny the command.
- An action can only be performed by a user who was not involved in an earlier stage. This means that a requesting user is not able to second or complete a command (WITHDRAW is allowed). Similarly, a user who seconds a command cannot complete it. It *is* allowed to HOLD a command and then APPROVE or DENY it. Also, if a user SECOND HOLDs a command, and the command is then SECOND APPROVED by another user, the user who performed the HOLD can still complete the command.

The following tables list the actions initiated by REQ and the actions on a queued command initiated by ASK.

Table 616. Actions for queued command initiated with REQ

Previous action	Action	Authority	Effect
REQUEST	WITHDRAW	ALL	Withdrawn and not executed.
REQUEST	SECOND DENY	TRIPLE	Denied and not executed.
REQUEST	SECOND HOLD	TRIPLE	Held; expiration delayed.
REQUEST	SECOND APPROVE	TRIPLE	Approved; completion has to follow.
REQUEST	COMPLETE DENY	DUAL	Denied and not executed.
REQUEST	COMPLETE HOLD	DUAL	Held; expiration delayed.
REQUEST	COMPLETE APPROVE	DUAL	Approved and executed.
SECOND HOLD	WITHDRAW	ALL	Withdrawn and not executed.
SECOND HOLD	SECOND DENY	TRIPLE	Denied and not executed.
SECOND HOLD	SECOND HOLD	TRIPLE	Held; expiration delayed.
SECOND HOLD	SECOND APPROVE	TRIPLE	Approved; completion has to follow.
SECOND HOLD	COMPLETE DENY	DUAL	Denied and not executed.
SECOND HOLD	COMPLETE HOLD	DUAL	Held; expiration delayed.
SECOND HOLD	COMPLETE APPROVE	DUAL	Approved and executed.
SECOND APPROVE	WITHDRAW	TRIPLE	Withdrawn and not executed.
SECOND APPROVE	SECOND DENY	*error*	Issue not allowed error.
SECOND APPROVE	SECOND HOLD	*error*	Issue not allowed error.
SECOND APPROVE	SECOND APPROVE	*error*	Issue not allowed error.
SECOND APPROVE	COMPLETE DENY	TRIPLE	Denied and not executed.
SECOND APPROVE	COMPLETE HOLD	TRIPLE	Held; expiration delayed.
SECOND APPROVE	COMPLETE APPROVE	TRIPLE	Approved and executed.
COMPLETE HOLD	WITHDRAW	ALL	Withdraw and not executed.
COMPLETE HOLD	SECOND DENY	*error*	Issue not allowed error.
COMPLETE HOLD	SECOND HOLD	*error*	Issue not allowed error.
COMPLETE HOLD	SECOND APPROVE	*error*	Issue not allowed error.
COMPLETE HOLD	COMPLETE DENY	ALL	Denied and not executed.
COMPLETE HOLD	COMPLETE HOLD	ALL	Held; expiration delayed.
COMPLETE HOLD	COMPLETE APPROVE	ALL	Approved and executed.

Table 617. Actions for queued command initiated by ASK

Previous action	Action	Authority	Effect
ASK	WITHDRAW	ALL	Withdrawn and not executed.
ASK	SECOND DENY	DUAL/TRIPLE	Denied and not executed.
ASK	SECOND HOLD	DUAL/TRIPLE	Held; expiration delayed.
ASK	SECOND APPROVE	DUAL/TRIPLE	Approved; completion has to follow.
ASK	COMPLETE DENY	SINGLE	Denied and not executed.
ASK	COMPLETE HOLD	SINGLE	Held; expiration delayed.
ASK	COMPLETE APPROVE	SINGLE	Approved and executed.
SECOND HOLD	WITHDRAW	ALL	Withdrawn and not executed.
SECOND HOLD	SECOND DENY	DUAL/TRIPLE	Denied and not executed.
SECOND HOLD	SECOND HOLD	DUAL/TRIPLE	Held; expiration delayed.
SECOND HOLD	SECOND APPROVE	DUAL/TRIPLE	Approved; completion has to follow.
SECOND HOLD	COMPLETE DENY	SINGLE	Denied and not executed.
SECOND HOLD	COMPLETE HOLD	SINGLE	Held; expiration delayed.
SECOND HOLD	COMPLETE APPROVE	SINGLE	Approved and executed.
SECOND APPROVE	WITHDRAW	ALL	Withdrawn and not executed.
SECOND APPROVE	SECOND DENY	*error*	Issue not allowed error.
SECOND APPROVE	SECOND HOLD	*error*	Issue not allowed error.
SECOND APPROVE	SECOND APPROVE	*error*	Issue not allowed error.
SECOND APPROVE	COMPLETE DENY	DUAL/TRIPLE	Denied and not executed.
SECOND APPROVE	COMPLETE HOLD	DUAL/TRIPLE	Held; expiration delayed.
SECOND APPROVE	COMPLETE APPROVE	DUAL/TRIPLE	Approved and executed.
COMPLETE HOLD	WITHDRAW	ALL	Withdraw and not executed.
COMPLETE HOLD	SECOND DENY	*error*	Issue not allowed error.
COMPLETE HOLD	SECOND HOLD	*error*	Issue not allowed error.
COMPLETE HOLD	SECOND APPROVE	*error*	Issue not allowed error.
COMPLETE HOLD	COMPLETE DENY	ALL	Denied and not executed.
COMPLETE HOLD	COMPLETE HOLD	ALL	Held; expiration delayed.
COMPLETE HOLD	COMPLETE APPROVE	ALL	Approved and executed.

ASK is not allowed for TRIPLE authority profiles.

Creating random passwords

The PWSET RANDOM option creates a random encrypted password to be stored in the user profile. If the password encryption exit (ICHDEX01 or ICHDEX11) is set to DES-only, this option makes it practically impossible to logon for the userid. Note, however, that there is *no absolute guarantee* that logon is impossible. The description of the password check that follows explains how the passwords created by the PWSET RANDOM option are secured:

- When DES-encryption is used and a password is set, the encrypted password is calculated by DES-encrypting the userid with a key computed from the unencrypted password. The encrypted password is then stored.
- When a password is entered to be verified, the entered password is encrypted in the same way, and the encrypted passwords are compared. The encrypted passwords must be equal to match.
- A DES-encrypted password cannot be decrypted. The encryption is also unique, in the sense that there is no other password that has the same encrypted result.
- There is no easy way to guess a DES-encrypted password. The only way to do this is to try *all* possible passwords, encrypting them, and comparing the encrypted passwords. If a guess is almost correct, in the sense that it differs from the password in a very small way, the encrypted passwords are likely to be completely different.
- If two userids have the same password, the encrypted passwords are completely different. (The userid is used in the DES-encryption). Similarly, when two encrypted passwords are identical, the unencrypted passwords are completely different.

When a random value is used as an encrypted password, there is no way to check how 'hard' it is. There is exactly one password that results in the encrypted value, but which password it is depends both on the userid and the random value. It is almost certain that the unencrypted password cannot be found, and that it cannot be entered from a keyboard even if it was found, but there is a remote possibility that it will be easy (SECRET, for example').

Warning about passwords

RACF commands issued through CMD or USER PWSET can be logged in SMF–depending on the audit level of the CKG.CMD.CMD profile–and written to the job output if CKGRACF is run in batch. These commands can show passwords and password phrases.

When a PASSWORD or PHRASE parameter is recognized in a RACF command, the secret value is replaced by a question mark. To prevent password collection from the SMF or the job log, make sure that the PASSWORD or PHRASE parameter is not abbreviated to fewer than 4 positions and that the left parenthesis is coded immediately following the parameter with no spaces. The following examples shows the logging for different formats:

`ALTUSER IBMUSER PASS(1234)` is logged as `ALTUSER IBMUSER PASS(?)` with no password displayed.

`ALTUSER IBMUSER PAS(1234)` is logged as-is to SMF, displaying the password.

`ALTUSER IBMUSER PASSWORD (1234)` includes a blank before the opening parenthesis and is logged as-is, displaying the password.

`ALTUSER IBMUSER PHRASE (1234)` includes a blank before the opening parenthesis and is logged as-is, displaying the password.

Protecting a userid with the PWSET NOPASSWORD option

The PWSET NOPASSWORD option changes the status of the userid to protected. Protected userids cannot be used to enter the system by any means that would normally require a password or password phrase to be specified, such as TSO logon, CICS signon, or typical batch job submission. Therefore, userids that you assign to z/OS UNIX, UNIX daemons, started procedures, applications, servers or subsystems can be protected from being revoked when an incorrect password or password phrase is entered. If the user attempts to enter the system with a password or password phrase, the attempt fails.

The status of the userid is set to unprotected with a USER PWRESET command or with a USER PWSET command which is not followed by the NOPASSWORD option.

USRDATA

The USRDATA command can be used to set, delete, or list entries in a profile's USR field. This field can consist of multiple entries, each containing an *index* (value of USRNM field) and *data* (contents, the value of USRDATA field optionally followed by the value of USRFLG field). The contents and index names are completely at the site's discretion; a common example is PHONE. The USRDATA command works on the USRDATA (and USRFLG) field, using the value of the USRNM field as an index. A restriction on the USRDATA command is that index names starting with CNG are reserved for use by CKGRACF; the USRDATA command cannot be used to alter or list these USR entries. Index names starting with $C4R are reserved for zSecure Command Verifier. zSecure Command Verifier maintains these USR entries, so you should not directly update them. We recommend that you establish profiles that cover resources CKG.USRDATA.*.*.$C4R*, with UACC(NONE), and ACCESS(READ) for the RACF administrators and auditors.

Also, discrete data set profiles are not supported.

The USRDATA command has the following syntax:

```
USRDATA class profile ADD     [ REASON(reason) ] index(data) ...
USRDATA class profile DELETE  [ REASON(reason) ] index ...
USRDATA class profile DELETE  [ REASON(reason) ] index(data) ...
USRDATA class profile LIST    [ REASON(reason) ] index ...
USRDATA class profile REPLACE [ REASON(reason) ] index(old-data,new-data) ...
USRDATA class profile SET     [ REASON(reason) ] index(data) ...
```

```
class             Any valid RACF class
profile           Any valid RACF profile
action            One of ADD, DELETE, LIST, REPLACE, or SET; see below
index             The index (USRNM value) for the USR entry, with optional
index(data)       values for the USRDATA/USRFLG field; see below
index(old-data,new-data)
reason            A reason string (Reason keywords in CKGRACF)
```

The profile can be specified with profile conversion characters (See also “Profile conversion in CKGRACF” on page 1500).

If no conversion character `D` or `G` has been specified, the effect depends on the profile type. Data set profiles are treated as generics, since discrete data set profiles are not supported. This implies that fully qualified generics need not be quoted. General resource profiles are treated 'as-is': they are treated as a generic if the

name contains generic characters, and as a discrete if it does not. Since fully qualified generics are not allowed for general resource profiles, quotes should never be necessary.

Note:

> For DATASET profiles, the full name must be specified. Unquoted data set profiles are *not* prefixed with the user's TSO prefix.

Each *data* value is a USRDATA value optionally followed by a slash (/) and a USRFLAG value. A USRDATA value must be specified as a string with a maximum size of 255 characters (quotes and conversions are allowed). An USRFLG value is a number between 0 and 255 which can be written in decimal form (e.g. 160) or hexadecimal form (e.g. 'A0'X). If an USRFLG value is to be specified, quotes around the preceding USRDATA value are obligatory. Without the quotes, the slash and the (decimal) value following it will be treated as part of the USRDATA value. The *action* determines whether a USRDATA (and USRFLG) value can or must be specified, as described in the following table.

Table 618. Actions for CKGRACF USRDATA

Action	Values	Effect	Example
ADD	one	Adds an USR entry with USRNM value *index* and USRDATA/USRFLG value *data*.	ADD *index(data)*
DELETE	none	Deletes all USR entries with USRNM value*index*.	DELETE *index*
DELETE	one	Deletes all USRDATA entries with USRNM value *index* and USRDATA/USRFLG value *data*.	DELETE *index(data)*
LIST	none	Lists the USRDATA field of all USR entries with USRNM value *index*. Note: an exact value must be specified, patterns are not allowed.	LIST *index*
REPLACE	two	If any USR entries can be found with USRNM value *index* and USRDATA/USRFLG value *old-data*, these are deleted and replaced by a single entry with USRNM value *index* and USRDATA/USRFLG value *new-data*.	REPLACE *index(old-data,new-data)*
SET	one	Deletes any USR entries with USRNM value *index*, if present; then adds a single USR entry with USRNM value *index* and USRDATA/USRFLG value *data*.	SET *index(data)*

More than one index can be specified in a single USRDATA command; the same action is applied to each of the indices and values in turn. The target profile is not changed if an error occurs within a single USRDATA command.

When the USRFLG value of an entry is not zero, the USRDATA LIST command will print it as a hexadecimal number after a slash after the corresponding, quoted, USRDATA value. When the USRFLG value is zero, the slash and hexadecimal number is not printed.

If the USRFLAG value is left away in ADD *index(data)*, or SET *index(data)*, or in the *new-data* of REPLACE *index(old-data, new-data)*, the USRFLG value will be 0 by default. If the USRFLG value is left away in DELETE*index(data)*, entries with USRNM value *index*, USRDATA value *data*, and any USRFLG value will be deleted. If the USRFLG value is left away in *old-data* of REPLACE *index(old-data, new-data)*, entries with USRNM value *index*, USRDATA value *old-data*, and any USRFLG value will be deleted before replacing them with *index(new-data)*.

The USRDATA command requires access to the command profile shown in the following table.

Table 619. Command access checks for CKGRACF USRDATA

Resource name checked	Access required
CKG.CMD.USRDATA	READ for the LIST option; UPDATE for all other options.

In addition, the target user must be within the userdata-scope of the command user (see "CKGRACF authority checks" on page 1559):

Table 620. USRDATA access checks for CKGRACF USRDATA

Resource name checked	Access required
CKG.USRDATA.OWN.*class.index*	READ for the LIST option; UPDATE for all other options.
CKG.USRDATA.ALL.*class.index*	READ for the LIST option; UPDATE for all other options.
CKG.USRDATA.SCP.*class.index*	READ for the LIST option; UPDATE for all other options.

If access to CKG.USRDATA.SCP.*class.index* is defined, the following profiles will be checked:

Table 621. Scope access checks for CKGRACF USRDATA

Resource name checked	Access required
CKG.SCP.ID.*userid.owner.dfltgrp*	READ for the LIST option; UPDATE for all other options.
CKG.SCP.ID.*groupid.owner*	READ for the LIST option; UPDATE for all other options.
CKG.SCP.G.*groups...*	READ for the LIST option; UPDATE for all other options.
CKG.SCP.U.*user.groups...*	READ for the LIST option; UPDATE for all other options.

Restrictions

There are several restrictions on the use of the USR field and the USRDATA command:

- The USRDATA command does not support discrete data set profiles. The reason is that most DASD management packages (including DMS and HSM) do not preserve the USR field on their backups of discrete profiles. This does not apply to generic profiles, so it is feasible to store e.g. data set account numbers in the generic data set profiles.

- The USRDATA command should not be used to store information that needs to be checked from RACF exits. This is because RACF does not read the info by itself and also does not cache it with the ACEE. Hence using the USR field from an exit might severely impact performance. Use an installation-defined RACLISTed profile class instead.
- The Security zSecure RECREATE command does not recreate the full USR field. It recreates the multiple-authority setting and installation-defined entries.
- The Security zSecure COPY command does not copy USR fields.

Example

In this example, we assume that index DB2PROJ indicates a DB2 project name. The central administrators set this value for each group using DB2, decentral administrators can list this value for groups within their scope.

We assume the following example profiles:

Table 622. Example profiles for CKGRACF USRDATA

Profile name	Central	Decentral	Comment
CKG.CMD.USRDATA	UPDATE	READ or UPDATE	Grant decentral administrators READ access if they cannot update any USR field; grant UPDATE if they may update some USR fields.
CKG.USRDATA.ALL.GROUP.DB2PROJ	UPDATE	NONE	Central administrators list and update DB2PROJ for all groups.
CKG.USRDATA.SCP.GROUP.DB2PROJ	NONE	READ	Decentral administrators list DB2PROJ for groups within their scope.
CKG.SCP.ID.*db2grp.db2ownr*.*	NONE	READ or UPDATE	Group scope for decentral administrators.
CKG.SCP.G.***.db2group...*	NONE	READ or UPDATE	Group scope for decentral administrators.

In this setup, a central administrator could set DB2PROJ for group DB2DEV using the command:

```
ckgracf usrdata group db2dev set db2proj('Developers')
```

A decentral administrator with group DB2DEV within his scope could display this value using the command:

```
ckgracf usrdata group db2dev list db2proj
```

WIPE

The WIPE command can be used to delete part of the USRDATA from user group, dataset, and general resource profiles, including the CKGRACF settings. The CKGRACF settings are stored in the profile's USR field, but cannot be altered by the USRDATA command. Use the LIST command (with the QUEUE or TAG option) to display these settings.

The WIPE command has the following syntax:

```
WIPE class profile action ... [ REASON(reason) ]

class     Any valid RACF class.
profile   Any valid RACF profile.
action    A WIPE action; one or more actions may be specified
reason    A reason string ("Reason keywords in CKGRACF" on page 1501)
```

The WIPE actions are specified in the following table.

Table 623. Actions for CKGRACF WIPE

Action	Meaning
ALL	Wipe all userdata entries
AUTHORITY	Wipe authority settings (same effect as AUTHORITY DEFAULT)
DEFAULTPW	Wipe the default password (same effect as USER PWDEFAULT DELETE)
INSTALLATION	Wipe all installation-defined USR entries (that is, all entries that are not reserved for use by CKGRACF)
QUEUE	Wipe all queued commands
RESERVED	Wipe all CKGRACF-reserved entries
SCHEDULE	Wipe the scheduled revoke/resume settings
UNDEFINED	Wipe all CKGRACF-reserved, undefined entries

For each option used, access is required to the command resource name shown in the following table.

Table 624. Command access checks for CKGRACF WIPE

Option	Resource name checked	Access required
ALL	CKG.CMD.WIPE.ALL	UPDATE
AUTHORITY	CKG.CMD.WIPE.AUTHORITY	UPDATE
DEFAULTPW	CKG.CMD.WIPE.DEFAULTPW	UPDATE
INSTALLATION	CKG.CMD.WIPE.INSTALLATION	UPDATE
QUEUE	CKG.CMD.WIPE.QUEUE	UPDATE
RESERVED	CKG.CMD.WIPE.RESERVED	UPDATE
SCHEDULE	CKG.CMD.WIPE.SCHEDULE	UPDATE
UNDEFINED	CKG.CMD.WIPE.UNDEFINED	UPDATE

The WIPE command is not subject to scope checks.

Note that WIPE SCHEDULE deletes *all* scheduled actions, and the schedule audit trail, from a profile. The USER SCHEDULE WIPE command wipes selected scheduled actions from a single schedule, and keeps an audit trail.

Example

In order to wipe *all* USR entries from the user profile IBMUSER, use CKGRACF WIPE USER IBMUSER ALL. In order to wipe all CKGRACF-defined entries (and leave all installation-defined entries), use CKGRACF WIPE USER IBMUSER RESERVED.

The CARLa script CKGXUSRW generates CKGRACF WIPE and USRDATA commands to delete USR entries. A command is generated for each type of entry; this allows you to keep those entries that you do not want to delete.

This CARLa script can be used with job C2RJXRFR in the SCKRSAMP library by specifying it as the MEMBER:

```
//CKRCARLA EXEC C2RC,MEMBER=CKGXUSRW,OPTCARLA=,ALLOCUNL=1,
//         CONFIG=C2R$PARM
```

CKGRACF authority checks

CKGRACF performs its own authority checks and logging through normal RACF requests. Authority to operate on user, group, general resource and data set profiles is regulated through CKGRACF scope profiles. Authority to the specific CKGRACF commands and options is regulated through CKGRACF command profiles. The authority to operate on individual fields is regulated through racfdata profiles. Authority to specific site-defined *schedules* and *userdata fields* is regulated through CKGRACF schedule profiles and userdata profiles.

The capabilities provided through CKGRACF are an addition to the standard RACF authority a user has; they do not reduce a user's authority unless you also take the standard RACF authority away (for example, replace standard RACF functionality by CKGRACF functionality).

The CKGRACF profiles reside in the XFACILIT class or another, installation-defined, class.

All these RACF profile types are explained in the following sections.

Command profiles

Access to the CKGRACF commands is determined using command profiles; these profiles start with CKG.CMD. CKGRACF checks a resource name of the form CKG.CMD.*command.action.option*; the qualifiers are used where applicable.

The following table lists the various resource names that CKGRACF checks:

Table 625. Command access checks for all CKGRACF commands

Command and option	Resource name checked
ACCESS	CKG.CMD.ACCESS.ALL
AUTHORITY *class*	CKG.CMD.AUTHORITY.*class*
CMD ASK CONNECT	CKG.CMD.CMD.ASK.CONNECT
CMD ASK DELDSD	CKG.CMD.CMD.ASK.DELDSD
CMD ASK PERMIT	CKG.CMD.CMD.ASK.PERMIT
CMD ASK RDELETE	CKG.CMD.CMD.ASK.RDELETE
CMD ASK REMOVE	CKG.CMD.CMD.ASK.REMOVE
CMD COMPLETE CONNECT	CKG.CMD.CMD.CMP.CONNECT

Table 625. Command access checks for all CKGRACF commands (continued)

Command and option	Resource name checked
CMD COMPLETE DELDSD	CKG.CMD.CMD.CMP.DELDSD
CMD COMPLETE PERMIT	CKG.CMD.CMD.CMP.PERMIT
CMD COMPLETE RDELETE	CKG.CMD.CMD.CMP.RDELETE
CMD COMPLETE REMOVE	CKG.CMD.CMD.CMP.REMOVE
CMD EXECUTE ADDGROUP	CKG.CMD.CMD.EX.ADDGROUP
CMD EXECUTE ADDSD	CKG.CMD.CMD.EX.ADDSD
CMD EXECUTE ADDUSER	CKG.CMD.CMD.EX.ADDUSER
CMD EXECUTE ALTDSD	CKG.CMD.CMD.EX.ALTDSD
CMD EXECUTE ALTGROUP	CKG.CMD.CMD.EX.ALTGROUP
CMD EXECUTE ALTUSER	CKG.CMD.CMD.EX.ALTUSER
CMD EXECUTE CONNECT	CKG.CMD.CMD.EX.CONNECT
CMD EXECUTE DEFINE	CKG.CMD.CMD.EX.DEFINE
CMD EXECUTE DELETE	CKG.CMD.CMD.EX.DELETE
CMD EXECUTE DELDSD	CKG.CMD.CMD.EX.DELDSD
CMD EXECUTE DELGROUP	CKG.CMD.CMD.EX.DELGROUP
CMD EXECUTE DELUSER	CKG.CMD.CMD.EX.DELUSER

Table 625. Command access checks for all CKGRACF commands (continued)

Command and option	Resource name checked
USRDATA	CKG.CMD.USRDATA
WIPE ALL	CKG.CMD.WIPE.ALL
WIPE AUTHORITY	CKG.CMD.WIPE.AUTHORITY
WIPE DEFAULTPW	CKG.CMD.WIPE.DEFAULTPW
WIPE INSTALLATION	CKG.CMD.WIPE.INSTALLATION
WIPE QUEUE	CKG.CMD.WIPE.QUEUE
WIPE RESERVED	CKG.CMD.WIPE.RESERVED
WIPE SCHEDULE	CKG.CMD.WIPE.SCHEDULE
WIPE UNDEFINED	CKG.CMD.WIPE.UNDEFINED

The access required to these profiles is READ for operations that list information, and UPDATE for operations that can change information. The PWCONVERT and RDELETE commands also require that the user has the system-wide SPECIAL attribute. In the command language reference, the description of each command notes the access required to the command profiles.

Note that for the USER, LIST, and USRDATA commands, access to the command profile is not sufficient. The USER and LIST commands require that the target user is within the scope of the command user; this requires access to the correct scope profiles. The USER SCHEDULE command also requires access to the target schedule; this requires access to the schedule profiles; see below. The USRDATA command requires access to the userdata index; this requires access to the userdata profiles; see below. The CMD command can require access to the racfdata profiles; also see below.

Scope profiles

Scope profiles are used to define the users, groups and profiles that lie within the scope of a user. They can for example be used to define a scope for a decentral administrator to CKGRACF. This scope is rather different from the RACF-defined scope for a group administrator. The CKGRACF scope is based upon the ownership-tree of a resource. Access through CKGRACF is regulated by the access granted by two different checks: ID profile checks (CKG.SCP.ID), and user/group (U/G) profile checks (CKG.SCP.U or CKG.SCP.G). ID profiles permit access directly based on the groupid/userid associated with the target object. SCP.U/G profiles use the ownership tree of the target object, with as top qualifier either a user (for SCP.U profiles) or a group (for SCP.G profiles).

Note that for all occurrences of CKG.SCP a profile with the identical function exists specifically for the ASK command stage. This profile is CKG.SCPASK. A requested command will check the CKG.SCP profiles, while an asked command will check the CKG.SCPASK profiles.

Using RACF-defined scopes with CKGRACF

READ or higher access to the CKG.SCP.RACF resource extends a user's CKGRACF scope with the user's RACF-defined scope. The following specification of this CKGRACF scope extension uses the concept of a *group owner chain*. The group owner chain of a user or group *id* is the sequence *groupx*, ..., *group2*, *group1*, *id* where *groupx* is equal to SYS1 or the owner of *groupx* or *id* is an userid, and where

each *groupx*, ..., *group2*, *group1* is a group which is the owner of the resource which immediately follows it. Note that if *id* is a group, it is included with the group owner chain of *id*.

If *userid* requests *access* to *resource*, and *userid* has READ access to CKG.SCP.RACF, then *resource* lies in the (*access*-dependent) CKGRACF scope of *userid* in any of the following cases.

- *userid* is the owner of *resource*
- the class of *resource* is DATASET and *userid* is equal to the HLQ (High-level qualifier) of *resource*
- *userid* is SPECIAL
- *access* is READ and *userid* is OPERATIONS or AUDITOR
- the class of *resource* is USER or GROUP and *userid* is GROUP SPECIAL in some group of the group owner chain of *resource*
- the class of *resource* is USER or GROUP, *access* is READ, and *userid* is GROUP OPERATIONS or GROUP AUDITOR in some group of the group owner chain of *resource*
- the class of *resource* is neither USER nor GROUP and *userid* is GROUP SPECIAL in some group of the group owner chain of the owner of *resource*
- the class of *resource* is neither USER nor GROUP, *access* is READ, and *userid* is GROUP OPERATIONS or GROUP AUDITOR in some group of the group owner chain of the owner of *resource*
- the class of *resource* is DATASET, the HLQ of *resource* is an user or group, and *userid* is GROUP SPECIAL in some group of the group owner chain of the HLQ of *resource*
- the class of *resource* is DATASET, the HLQ of *resource* is an user or group, *access* is READ, and *userid* is GROUP OPERATIONS or GROUP AUDITOR in some group of the group owner chain of the HLQ of *resource*

Since CKGRACF is intended for administrative functions only, there is one difference between normal RACF scoping rules and CKGRACF. RACF allows a partial list of a profile to which a user has a read (or higher) permit. CKGRACF only allows full listing of profiles, and will therefore not consider these profiles within scope.

If *userid* does not have READ access to CKG.SCP.RACF, or none of the cases above holds, then the CKGRACF scope rules of the previous section come into play.

CKG.SCP.ID: the ID resource names

Table 626. ID scope profiles for CKGRACF

Class of resource	CKGRACF resource name checked
USER	CKG.SCP.ID.*userid.owner.dfltgrp*
GROUP	CKG.SCP.ID.*groupid.owner*
GENERAL	The owner of the resource is determined, and a check is done for this user or groupid.
DATASET	The owner of the data set is determined, and a check is done for this user or groupid. On failure of this check, the HLQ is taken, and a check is done for that user or groupid.

Note that if you specify an explicit user or group in an ID profile, the owner will generally not change, so "*" should suffice. Similarly, it is recommended that you use "*" for the default group, since a user is usually able to change her default group at login, and this could have unintended effects on the scope definitions.

CKG.SCP.U/G owner tree resource names

The owner tree based scope access is defined by two formats of resource names:

- CKG.SCP.U.*top.ownerx...owner2.owner1* (where *top* is a user)
- CKG.SCP.G.*top.ownerx...owner2.owner1* (where *top* is a group owned by SYS1)

For these resources, *top* is the owner of *ownerx*, *owner2* is the owner of *owner1* and *owner1* is the owner of *id* (see below).

Only one of these resources will be checked, dependent on whether *top* is a user or a group.

The *id* that is owned by *owner1* is determined as follows:

Table 627. Basic IDs for ID scope construction in CKGRACF

Class of resource	Basic id for resource construction
GROUP	The groupid itself
USER	The owner of the user profile
GENERAL	If the owner is a group, that groupid. If the owner is a user, the user's owner.
DATASET	If the owner is a group, that groupid. If the owner is a user, the user's owner. On failure of this check, the HLQ is taken and is processed similarly.

The ownership tree is travelled upwards from the basic id (see table above), until either a user or the group SYS1 is encountered. If a user is encountered, CKG.SCP.U is used, otherwise CKG.SCP.G is used. Creation of this resource happens by travelling down the ownership tree from the top id, and adding every encountered owner to the profile name.

The group SYS1 is never explicitly added to the resource, unless it's the only group in the ownership tree.

For example a user USER, has group OWNER1 as owner, which in turn is owned by group OWNER2; OWNER2 has group SYS1 as owner, thus terminating the tree. Creating the resource will form CKG.SCP.G.OWNER2.OWNER1

It is not necessary to define both SCP.ID and SCP.U/G profiles for every user and group. CKGRACF interprets a profile not found condition as denied access.

CKGRACF allows the request if either of the resources listed is permitted. We recommend that there is a high level generic CKG.** that disallows all access.

The following figure shows a simple group tree and the resulting SCP and ID resource names. A rounded box represents a user, a square box represents a group and a stretched hexagon represents a data set or general resource. The group tree shows the ownership structure, *not* the subgroup/supgroup structure. Profiles marked with *) are used only for data set resources.

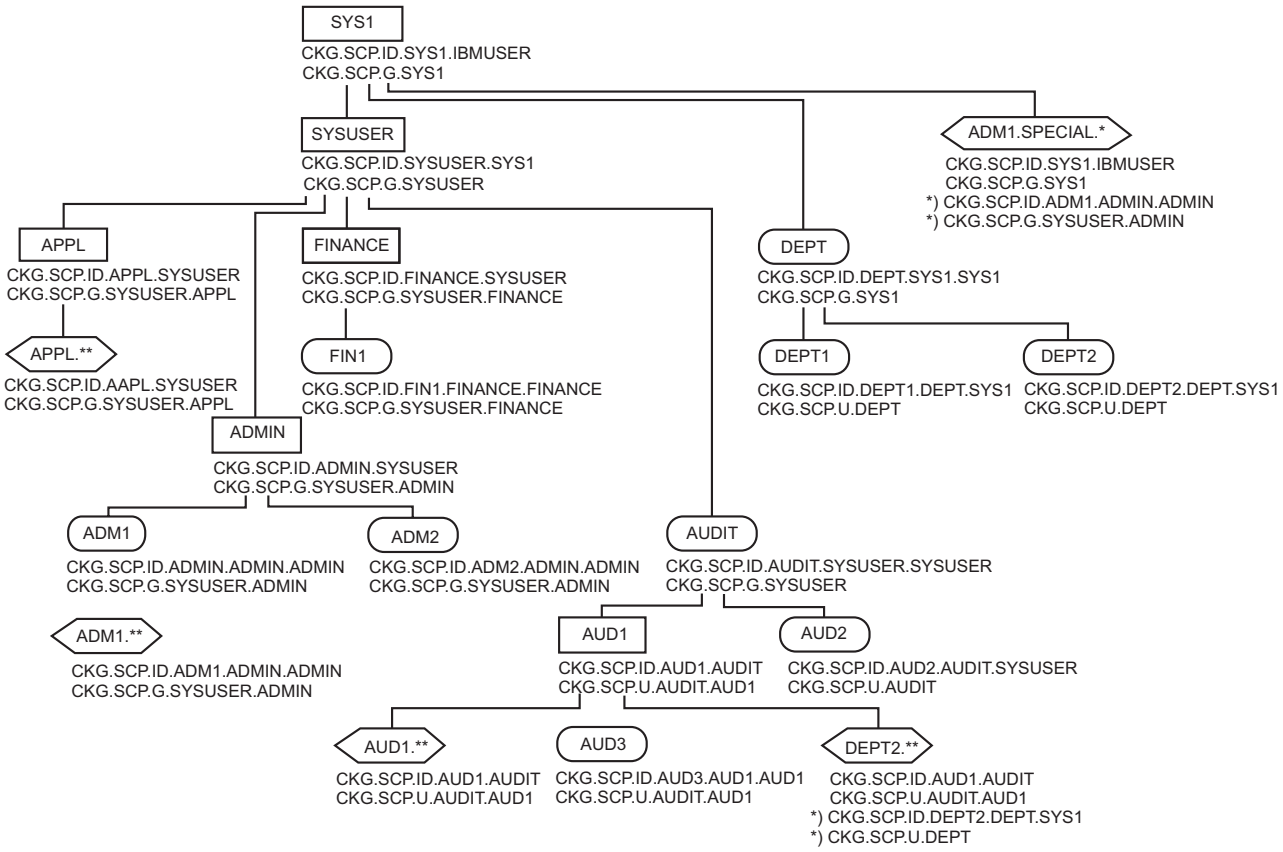

Figure 526. Group tree and scope profiles

For the group tree displayed in the preceding figure, the following scope profiles could be created:

Table 628. Examples for scope checking in CKGRACF

Profile	Comment
CKG.SCP.ID.*.ADMIN.*	All users owned by group ADMIN
CKG.SCP.ID.*.DEPT.*	All users owned by user DEPT
CKG.SCP.U.AUDIT	All users owned by user AUDIT
CKG.SCP.U.AUDIT.*	All users and groups owned 'downstream' of user AUDIT, e.g. user AUD3.
CKG.SCP.G.SYSUSER	All users owned by SYSUSER
CKG.SCP.G.SYSUSER.*	All users and groups owned 'downstream' of SYSUSER, unless the ownership is broken by a user.

Given these profiles, a scope check for user ADM2 first checks CKG.SCP.ID.*.ADMIN.*, and if access was not granted, check CKG.SCP.G.SYSUSER.*. User DEPT is not covered by any of these profiles, and is outside of any scope; access is denied to all administrators.

Permitting a user on the CKG.SCP.**.AUD1.* and the CKG.SCP.**.AUD1 profile is equivalent to giving him group-special on the AUD1 group (with regard to scope; the comments allowed can be restricted). The * and ** masks represent any number of qualifiers. So the profile matches any user below AUD1, irrespective of the groups and users between AUD1 and SYS1.

The table shows the resource names checked:

Table 629. Scope access checks for CKGRACF

Resource name checked	Access required
CKG.SCP.ID.*userid.owner.dlftgrp*	READ for LIST commands and UPDATE for all commands that modify a profile
CKG.SCP.ID.*groupid.owner*	READ for LIST commands and UPDATE for all commands that modify a profile
CKG.SCP.G.*groups...*	READ for LIST commands and UPDATE for all commands that modify a profile
CKG.SCP.U.*user.groups...*	READ for LIST commands and UPDATE for all commands that modify a profile

Restriction on scope profiles

Bear in mind the fact that the total length of a scope profile (including the prefix), can never be more than the maximum length allowed in the class these profiles are put in.

Using GLOBAL profiles

In some installations, all users are allowed to list or update their own user resource. For example, users can be allowed to LIST their own userid or to enter their own holiday schedule. While it is possible to give individual users *u* READ or UPDATE access to individual CKG.SCP.ID.*u*.** profiles, it can be more convenient to have a single profile member CKG.SCP.ID.&RACUID.**/READ or CKG.SCP.ID.&RACUID.**/UPDATE in the GLOBAL class. With such a member in place, there is no need to define individual CKG.SCP.ID.*u*.** profiles any more. Note though that if a user gets access to a resource through a member in the GLOBAL class, RACF will perform no further processing - not even auditing.

Userdata profiles

Userdata profiles can be used to set the scope for the USRDATA command. This scope check is performed only if the access check to the command profile (CKG.CMD.USRDATA) has been successful. The scope for the USRDATA command is based on the resource class, the resource owner, and the *index* (value of the USRNM field) used. The USRDATA command cannot be used to access USR entries reserved for use by CKGRACF; these have index values starting with 'CNG'. All other indices are free to be used by the installation as they see fit, e.g. an index 'PHONE'.

The scope check for the USRDATA command can have up to three steps:

- If the target profile is the current user (class is USER), or if the owner of the target profile is the current user (class is not USER), the 'own profile' resource is checked. This profile can be used to grant users access to their own profiles for a class and index value. The resource name checked is CKG.USRDATA.OWN.*class.index*. USRDATA LIST actions require READ access, other actions require UPDATE access.
- If the 'own profile' check fails or does not apply, the 'all profile' resource is checked. This profile can be used to grant system-wide access to *all* USR entries for a class and index value. The resource name checked is CKG.USRDATA.ALL.*class.index*. USRDATA LIST actions require READ access, other actions require UPDATE access.

- If the 'all profile' check fails, the 'scope profile' resource is checked. This profile can be used to grant access to the USR entries for all profiles within the CKGRACF-defined scope for a class and index value. The resource name checked is CKG.USRDATA.SCP.*class.index*. USRDATA LIST actions require READ access, other actions require UPDATE access. If this access check succeeds, the scope profiles are checked; if the scope access check succeeds also, access to the userdata is granted.

The table shows the resource names checked:

Table 630. USRDATA scope checks for CKGRACF

Resource name checked	Access required
CKG.USRDATA.OWN.*class.index*	READ for the LIST option; UPDATE for all other options
CKG.USRDATA.ALL.*class.index*	READ for the LIST option; UPDATE for all other options
CKG.USRDATA.SCP.*class.index*	READ for the LIST option; UPDATE for all other options

Racfdata profiles

Racfdata profiles are used to protect individual fields in a profile, by means of access level checks and an internal multiple-authority setting. These profiles are checked by the CMD command when parsing the RACF command given with CMD. This profile check is only performed if the access check on the command profile (CKG.CMD.CMD) was successful.

A racfdata (RAC) profile contains qualifiers for *class*, *segment*, *field*, and sometimes *value*. E.g. CKG.RAC.SCP.DATASET.BASE.ACCESS.ALT would protect the ACCESS LIST of each data set within a user's CKGRACF-defined scope. Giving a user an access of READ (or NONE) to this profile will prevent her to give other users ALTER access via the CKGRACF PERMIT command for all data sets within the scope. RACF `DATASET` profiles as indicated in the following table do not apply to CKGRACF CMD EX commands, but only to CKGRACF CMD REQ CONNECT, DELDSD, PERMIT, RDELETE, and REMOVE commands.

The access needed on a racfdata profile is READ for all commands that list a *field* and UPDATE for all commands that modify a *field*.

Access to a field is granted if and only if any of the following conditions holds:

- The current user is the target profile (class is USER) or the owner of the target profile (class is not USER), and the current user has the required access to the 'own profile' resource CKG.RAC.OWN.*class.segment.field*.
- The current user has the required access to the 'all profile' resource CKG.RAC.ALL.*class.segment.field*.
- The target profile lies within the CKGRACF-defined scope of the current user, and the current user has the required access to the 'scope profile' resource CKG.RAC.SCP.*class.segment.field*.

'Own profiles' can be used to grant users access to fields of their own profiles, while 'all profiles' can be used to grant system-wide access to fields. Similarly, 'scope profiles' can be used to grant access to fields of profiles within CKGRACF-defined scopes of users.

If access to a field is granted, the internal multiple-authority setting for the involved profile will be used to determine the actual multiple-authority of the command. When determining this multiple-authority, 'own profiles' take precedence to 'all profiles', which in turn take precedence to 'scope profiles'.

The table shows the resource names checked:

Table 631. RAC profile checks for CKGRACF

Resource name checked	**Access required**
CKG.RAC.OWN.*class.segment.field*	READ for listing the *field*; UPDATE for modifying a *field*
CKG.RAC.ALL.*class.segment.field*	READ for listing the *field*; UPDATE for modifying a *field*
CKG.RAC.SCP.*class.segment.field*	READ for listing the *field*; UPDATE for modifying a *field*

The following table shows the indexes for RAC profiles and their description.

Table 632. RAC profile descriptions for CKGRACF

CKG.RAC profiles	**Description**
class.BASE.ACCESS.READ	Checked for access set to READ
class.BASE.ACCESS.UPD	Checked for access set to UPDATE
class.BASE.ACCESS.ALT	Checked for access set to ALTER
class.BASE.ACCESS.CTRL	Checked for access set to CONTROL
class.BASE.ACCESS.NONE	Checked for access set to NONE
DATASET.BASE.ACCESS.EXEC	Checked for access set to EXECUTE
PROGRAM.BASE.ACCESS.EXEC	Checked for access set to EXECUTE
class.BASE	Checked for deletion of the access list
class.WHEN.APPCPORT	Checked for setting of conditional access for APPCPORT
class.WHEN.CONSOLE	Checked for setting of conditional access for CONSOLE
class.WHEN.JESINPUT	Checked for setting of conditional access for JESINPUT
class.WHEN.PROGRAM	Checked for setting of conditional access for PROGRAM
class.WHEN.TERMINAL	Checked for setting of conditional access for TERMINAL
class.WHEN	Checked for deletion of conditional access list
CONNECT.BASE.ADSP	Checked for turning on the ADSP flag on CONNECT
CONNECT.BASE.SPECIAL	Checked for turning on the SPECIAL flag on CONNECT
CONNECT.BASE.OPERATIO	Checked for turning on the OPERATIONS flag on CONNECT
CONNECT.BASE.AUDITOR	Checked for turning on the AUDITOR flag on CONNECT

Table 632. RAC profile descriptions for CKGRACF (continued)

CKG.RAC profiles	Description
CONNECT.BASE.GRPACC	Checked for turning on the GRPACC flag on CONNECT
CONNECT.BASE.REVOKE	Checked for setting of REVOKE flag on CONNECT
CONNECT.BASE.RESUME	Checked for setting of RESUME flag on CONNECT
CONNECT.BASE.UACC.NONE	Checked for setting of UACC NONE flag on CONNECT
CONNECT.BASE.UACC.READ	Checked for setting of UACC READ flag on CONNECT
CONNECT.BASE.UACC.CON	Checked for setting of UACC CONTROL flag on CONNECT
CONNECT.BASE.UACC.UPD	Checked for setting of UACC UPDATE flag on CONNECT
CONNECT.BASE.UACC.ALT	Checked for setting of UACC ALTER flag on CONNECT
CONNECT.BASE.OWNER	Checked for definition of OWNER on CONNECT
CONNECT.BASE.AUTH.USE	Checked for Authority USE on CONNECT
CONNECT.BASE.AUTH.CREATE	Checked for Authority CREATE on CONNECT
CONNECT.BASE.AUTH.JOIN	Checked for Authority JOIN on CONNECT
CONNECT.BASE.AUTH.CONN	Checked for Authority CONNECT on CONNECT

Schedule profiles

Schedule profiles can be used to grant access to a revoke/resume schedule for a user (see also the explanation of schedules in "USER" on page 1533). These profiles are checked for a USER SCHEDULE command; the access check is performed only if the access check to the command profile (CKG.CMD.USER.*action*.SCHEDULE) has been successful. CKGRACF checks a resource name of the form CKG.SCHEDULE.*schedule*, where *schedule* is the name of the target schedule.

The following table lists the resource name checked by CKGRACF:

Table 633. SCHEDULE profile checks for CKGRACF

Resource name checked	Access required
CKG.SCHEDULE.*schedule*	UPDATE

Schedule names must be alphanumerical and 1 to 8 characters long. A schedule profile should be created for every type of independent reason for which a user could be revoked (separation of users into groups is done using the scope profiles; there is no need to create a schedule for each decentral administrator).

For instance, at a site where the system administrator, decentral administrators, and personnel administrator are allowed to revoke and resume a userid, the schedules SYSTEM, GROUP, and PAYROLL could be used. Any administrator should have access only to the schedule that he can use. Since a user is revoked if

revoked by *any* schedule, the system administrator does not require access to the GROUP and PAYROLL profiles. We advise you to choose schedule names in a meaningful way, and create a schedule name for each type of reason a user could be revoked; e.g., use the REVOKE schedule with access for one user only to provide a 'hard' revoke. You should also create a catchall profile CKG.SCHEDULE.* with access NONE for all users, to explicitly forbid the use of undefined schedules and to allow the logging of such failed attempts.

The following table shows the profiles that should be created:

Table 634. Example of SCHEDULE profiles in CKGRACF

Profile name	**Access required**	**Meaning**
CKG.SCHEDULE.*	NONE	Catchall profile for undefined schedules
CKG.SCHEDULE.*schedule*	UPDATE	Access to schedule *schedule*

Chapter 15. Problem Determination Guide

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•	•	•	•	•	•	•

Getting information for problem diagnosis

The first step in analyzing the problem is usually to obtain and save the SYSPRINT of the run. It can be accessed through the RESULTS panel (described in "RESULTS - View output and results" on page 24) or directly through the ISPF primary command SYSPRINT (unless the application crashed).

If the application has crashed and you are still in ISPF, it can usually be accessed by using

```
TSO ISRDDN
```

and looking for a CKR*x*MSG file, where *x* is the ISPF screen number. The data set name ends in `SYSPRINT`. If ISPF has also terminated, you can look for a data set under your current prefix ending in "SYSPRINT".

General problems and abends

Provided that the zSecure installation instructions are followed and all batch JCL and parameters are correctly tailored to reflect the configuration and standards at your own installation, you should not experience any problems in normal usage of zSecure. If abend codes *are* encountered when running zSecure, see Abends and other problems for further advice.

If your installation uses hot-standby volumes which are online when zSecure is being executed, see Handling hot-standby volumes for details of the SUPPRESS command, which you can use to cause zSecure to ignore those volumes.

Installations using Alternate Master Catalogs should review sections Handling alternate master catalogs and Handling catalog/VVDS inconsistencies to understand the problems which can occur in DFP, RACF, and zSecure in this type of environment.

Finally, the possibility exists that past system failures, software errors, etc. may have caused inconsistencies in the RACF database which you are unaware of but which zSecure highlights for you. Advice on the necessary actions to take can be found in Handling database layout problems.

Handling hot-standby volumes

A difficulty in the processing of zSecure is introduced by the use of *hot-standby* volumes. These volumes contain a track image copy of another volume, only the volume label is different (to be able to make the copy online). Typically, no profiles are copied. This automatically would result in a large number of error messages by the VERIFY PROTECTALL and VERIFY INDICATED functions, if discrete profiles are present for the volume. In addition, this might confuse in particular the resource deletion functionality in the MOVE, REMOVE and VERIFY commands.

For this kind of volume, zSecure provides a way to suppress all error messages and resource-oriented commands. This is done by means of the following command:

```
SUPPRESS VOLUME=volume
```

More than one command may be present indicating different volumes.

Sample output is shown in the following figure. Only the relevant sections are included in the following figure.

```
Include CKRALLOC (ISPF variable)
    2 |/* Data from DD070525 */
    3 |alloc type=UNLOAD dsn='SYSAPPL.CNRACF.DD070525.UNLOAD'  complex=DD070525
    4 |
    6 |alloc type=IOCONFIG dsn='SYSAPPL.CNRACF.DD070525.IOCONFIG'  complex=DD070525
    7 |
    9 |alloc type=CKRCMD DD=CKR02CMD
End of  CKRALLOC (include level 1)

Include CKRCMDV  (ISPF variable)
    1 |SUPPRESS VOLUME=WORKPK

Figure 527. Sample SUPPRESS VOLUME= output

Handling alternate master catalogs

Alternate master catalogs generally cause difficulties since by their purpose they provide the same function as the real master catalog. This implies that data sets cataloged in the master catalog are also cataloged in the alternate master catalog. However, VSAM data sets cataloged in multiple catalogs cause problems for DFSMSdfp, RACF, and zSecure.

For DFSMSdfp, a DIAGNOSE of the alternate master catalog will complain: the VVDS points to only one catalog, the other catalog disturbs the one-to-one relation between VVDS and catalogs.

For RACF discrete profiles, the volume name in the profile is the volume where the catalog resides, rather then the data set. Potentially, this is a security exposure if some day the alternate master catalog needs to be used - data sets that were protected by a discrete profile when they were created, are not protected anymore by this profile if the alternate master catalog is used, since the resource that RACF searches a matching profile for now contains a different volume (and of course the alternate master catalog will not reside on the same volume as the production master catalog).

For zSecure, the problem is: which profile must be considered the right one? Error messages generated for VSAM data sets cataloged in a master catalog need careful inspection. For instance, after creating a new z/OS image, page data sets are often cataloged in the wrong catalog (the one of the driving image instead of the one of the new image), or may have the wrong volume in their profiles (if you use discrete profiles).

Some problems may be addressed by using the SUPPRESS option to indicate which catalog should not be considered:

```
SUPPRESS CAT=datasetname
```

Note that the resource-handling functionality in the COPY, MOVE, REMOVE and VERIFY commands will DEFINE/DELETE catalog aliases in master catalogs as long as they are addressable from the current system (whether they are active or not) unless suppressed.

The problems can be prevented by:

- Not using the alternate master catalog, but relying on full-volume restore in case of master catalog problems.
- Not using discrete dataset profiles. Generic profiles do not contain a volume name, so they do not suffer from the preceding problems.

Handling catalog/VVDS inconsistencies

As discussed in the previous section, catalog/VVDS inconsistencies can be expected for VSAM data sets cataloged in the master catalog. Sometimes, other problems exist. Security zSecure generates error messages for these problems. These should be checked by using the IDCAMS DIAGNOSE command on the catalog and VVDS involved. Special care should be taken with these inconsistencies in relation to some VERIFY commands to identify *unused* generic or discrete profiles, and in relation to the resource deletion functionality in some MOVE, REMOVE and VERIFY commands (uncataloged non-VSAM data sets will be scratched from the VTOC, but orphan NVRs and VSAM errors will not result in any commands to remove the affected objects).

Handling VSAM on shared DASD

Shared DASD containing VSAM data sets may not be easy to understand, and zSecure contains a lot of code to help you. For each system, the normal catalog access path to be used may be different. In fact, this happens in almost all systems - primarily with data sets cataloged in the master catalog, but it might also happen because of differences in alias pointers (due to the lack of maintenance procedures that allow alias pointers to be defined in only one master catalog).

Since physically different catalog entries may describe the same data set (components) on a volume, the RACF indicated bits of VSAM clusters may be inconsistent - and the volumes to be used for a discrete VSAM profile may differ also.

Also, it may happen that components of identically named clusters on different systems *are* indeed physically different - the components may even have exactly the same name and the same volume serial. This happens for instance if multiple systems are run with their own, identically named, non-shared IPL volumes or IPL strings (IPL strings may be generated as an exact image copy of each other and then run non-shared for performance, maintenance, and availability reasons). It can even happen (although it is a threat to availability) that one cluster entry in a catalog on shared DASD is used to access two physically different, identically named components on identically named, non-shared DASD volumes.

To handle these complexities, zSecure processes a VSAM cluster name in a catalog on shared DASD for each system sharing the catalog volume, and it also processes each VSAM component on shared DASD for all systems sharing the component's volume. During this processing, the consistency of the catalog(s) with VTOC and VVDS is checked, and it is also checked whether a cluster component in a connected catalog resides in the catalog where the normal VSAM search sequence would look for it (through the system's master catalog alias matching the cluster name). If there is no system where a VSAM cluster would be found through the

normal search sequence, a message is generated. If there is no system where a cluster *component* is cataloged, a message is generated as well.

Currently, it is not fully identified *on which system* and *on which physical volume* a VSAM data set should be considered *sensitive*. This causes the REPORT SENSITIVE command to potentially report multiple copies of identically named VSAM clusters as sensitive, where actually only one of those clusters is really the sensitive one.

Handling database layout problems

Due to system failures, software errors, or other calamities, the RACF database may contain inconsistencies in its internal layout. A number of these inconsistencies is identified in error messages by zSecure. Some inconsistencies may not be intercepted, but may still provide you with unexpected output from Security zSecure.

For instance, zSecure may report on a profile that you cannot display with RACF commands. If this is the case, or if you receive messages on invalid segment identifiers or BAM block problems, you can run the RACF utility IRRUT200 to check the consistency of the database.

Typically, you find BAM block conflicts for the segments containing the profiles that are giving you problems. If you have a BAM block conflict that shows segments as allocated, while the index does not point to the segments, and zSecure erroneously processes the (partially) deleted profile, you can instruct Security zSecure to skip the profile. To do this, you must know the database number and RBA of the profile. The LIST keywords DB and RBA can help here:

```
SELECT ... /* the offending profile */
LIST CLASS, KEY, DB, RBA
```

To skip the offending profile in subsequent runs, you can explicitly exclude it from processing:

```
EXCLUDE DB=num, RBA=hexnum
```

If your problem is the other way around - you miss a profile that RACF can find but zSecure cannot find, this can only be solved by repairing the BAM block conflict with BLKUPD.

Abends and other problems

The most common system abend codes encountered with zSecure are listed in this topic along with a suggestion for the possible cause and remedy. Of course your first check should be the appropriate message manual for your operating system, that tells you the exact meaning of the abend and reason code.

001
Probably problems with blocksize. Look at the message in your job log to determine the DDname.

002
Problems with the DCB parameters of a file. Look at the message in your job log to determine the DDname. Check your specification for DCB parameters with the reference material in “Starting zSecure programs using JCL” on page 690.

30D
Access denied to load a non-controlled module while a PADS data set is open.

Typically, this happens in split-screen mode in ISPF/PDF while a zSecure display is active on the other screen. Review the messages to find which module is not controlled, and add a PROGRAM profile with NOPADCHK if you must use the application simultaneously with zSecure.

322
CPU time limit exceeded. Check the joblog for prior abend messages with a different abend code. If a prior abend occurred, solve this abend. Otherwise, increase the TIME parameter on the JOB card, code less functions together, or split the input (for example, per volume or only one RACF or ACF2 data set).

522
Check in the job log that the job was not waiting for a tape mount or offline or inaccessible device.

722
Too many output lines. Make your selection more specific or increase the output limit for your job (for instance with a /*JOBPARM L=*nn* card, where *nn* is thousands of lines allowed).

80A
878
GETMAIN error. Try to increase the REGION parameter on the EXEC or JOB card. If you have reached your site's maximum, code less functions together, or split the input (for example, per volume or per RACF or ACF2 data set).

913-74
This abend is issued for a log stream if it does not exist or if you do not have the SAF access to open it. It can also indicate other SUBSYS errors, so it is not very specific.

913
Access denied to one of the data sets. If running a batch job, review the ICH408I messages in the joblog to determine which one. If running interactively, you should have received an ICH408I message. If not, issue the TSO PROFILE WTPMSG command and try it again, you should now receive an ICH408I message.

D37
B37
One of the output data sets was too small, or there was no space left on the volume to extend the data set. Look at the message in your joblog to determine the DDname.

User Abends
Generally these errors are accompanied by a high severity message in the `SYSPRINT` indicating the specific problem and possible solutions. If this information is not included in the `SYSPRINT`, submit an error report to IBM software support.

Most abends (except some I/O related abends) are accompanied by a summary dump. For assistance on a problem by zSecure, you generally have to provide at least this summary dump, the JCL used, and the listing of the input commands.

Problems and abends in zSecure Collect

For information about CKF*xxxa* messages and abends that happen in zSecure Collect, see the *IBM Security zSecure: Messages Guide*.

Handling problems and abends in the Audit component of zSecure

This section describes problems specific to the Audit component of zSecure:

- Virtual memory requirements
- Response time problems

For information about general problems and abends, see "General problems and abends" on page 1573.

Virtual memory requirements Because of the nature of processing SMF logging data, the zSecure user must always keep in mind the size of SMF data sets, and the number of records selected in a query. The ISPF queries assume that virtual storage is large enough to store detailed information for all selected records. If you want to process a large amount of records, you should either make your query very selective (for example, select only a few records), or store less detailed information for each record selected (e.g. by specifying only a few fields on a custom query).

If zSecure is used on TSO, it can be used most efficiently using live SMF or a disk copy of the SMF data for one day. The disk copy does not need to contain all the SMF records for the day, but just the types that are being used in normal zSecure SMF queries. You can use the CKAJFUNL sample to create an online copy from the live SMF data set, or from a cumulative SMF tape.

When running a query using the ISPF interface, you need at least 5 MB virtual storage, but at least 32 MB is recommended. Large sites may need a region of 128 MB. zSecure uses virtual storage above the 16 MB line when available. If zSecure runs out of memory, SMF input file processing is terminated, and output is produced for the SMF records read until memory ran out. Early termination of SMF processing is indicated by message CKR0438 'SMF input terminated: out of memory' in the SYSPRINT file.

While a query is executing, the number of SMF records successfully processed is constantly shown. If for any reason a query should terminate because of insufficient memory, you can use the record number last shown as an upper limit and specify this number in the **Max number of records to read** field on the SMF **report parameters** panel. (See "Interactive SMF processing for RACF" on page 550.)

Alternatively, you can limit the number of SMF records selected for each group of record displays. The **Max number of records per display group** field can be used to set an upper bound to the number of records kept for each type of records.

Depending on the type of SMF records used in a query, it can save a lot of memory to disable the use of CKFREEZE data. For example, the configuration information provided through CKFREEZE data is of little use when only RACF event records are being used.

The job tag caching system is used to find the RACF or ACF2 userid for non-RACF or non-ACF2 activity records. If this option is set to YES or MINIMAL, this keeps in-storage the RACF or ACF2 userid, group, and terminal for every job when it can find this information, and uses it to complete non-RACF or non-ACF2 activity records. If set to YES, zSecure *caches* records until the record can be completed; for example, until the first SMF 30 record for the job is found. This may use several MB of memory. When memory is tight, set this parameter to MINIMAL. In this

case, records are not cached and all activity records occurring before the first SMF 30 record are not completed. Usually, these are records for jobs that were started before the begin of the SMF trace; if your SMF data is badly out of chronological order, this can occur for most jobs. If you are just reporting on RACF or ACF2 event records, you can set this option to NO in order to completely turn off the caching function. You can further tune the job tag caching system by putting an SMFCACHE command in the preamble (menu option **SE.3**).

Response time problems zSecure reports the progress of its data processing phase using ISPF messages. This helps to determine the amount of time zSecure spends in the different phases of the query. If running the query takes too long, and reading CKFREEZE data is a significant portion of the processing time, disabling the use of CKFREEZE data can speed up processing.

This might decrease the reliability of the reports. For example, it cannot find the cluster name for a VSAM component, it cannot decide if a data set is protected through a discrete or a generic profile, and it cannot find UNIX pathnames. In most instances, this does not present a problem, but in case of doubt always run your query again with CKFREEZE data.

A long response time can also be caused by excessive paging or CPU usage. In these cases, it can help to limit the number of SMF records processed for your query.

If a query takes too much time, you can interrupt SMF processing using the ATTN key. If the ATTN key is pressed, SMF input file processing is terminated. Output is produced for the SMF records read until ATTN was pressed. Early termination of SMF processing is indicated by message CKR0437 'SMF input terminated by user attention request' in the SYSPRINT file.

Creating a dump under ISPF

Standard procedure to create dumps under ISPF.

When programs running under ISPF have an abend, ISPF traps the abend and prevents any subsequent dump. If you need a dump in SYSABEND or SYSMDUMP, there are two options:

- start ISPF with the option TEST, so in linemode TSO (READY) type
  ```
  ISPF TEST
  ```
- in an existing ISPF session, type on the **Command ===>** line
  ```
  ENVIRON ENBLDUMP ON
  ```

When a program crashes, you now see a normal diagnostic dump on your terminal and the message

```
* ISPF SUBTASK ABEND *
IKJ56641I EXEC     ENDED DUE TO ERROR+
READY
```

At this point press ENTER to write a dump to SYSABEND or SYSMDUMP.

Note that the SYSUDUMP in most sites does not contain the user subpools. This makes it insufficient for problem determination.

An abending program running under ISPF can cause a follow-on abend in ISPF itself. For this reason, if you are writing a dump to a data set, make sure that the data set is allocated DISP=MOD - otherwise the dump associated with a follow-on abend will overwrite the original one.

By default, zSecure does not pass on abends to ISPF. Hence, for the purpose of creating a dump, you should specify **Pass abends to ISPF** under SETUP TRACE see "SE.T Setup - Trace" on page 1673.

Debugging menu option and action character problems

The menu options that display in the ISPF panels can be customized for the installation and also customized for individual users. The following factors determine what shows up on the menus.

- The IBM Security zSecure products installed. That is, if you have multiple products installed or different combinations of products, the menu options will be different.
- The SYS1.PARMLIB member IFAPRDxx
- The NLS tables used to translate the menus.
- Checks on resource names starting with CKR.OPTION and CKR.ACTION in the class configured in the CKRSITE module.

To troubleshoot menu issues, you can allocate a RECFM=VBA,LRECL=137 data set to file C2RIMENU. After you have allocated the file, startup data is written to the file during application startup. The data provides details about the following:

- The NLS members selected and reasons they were selected.
- The SAF checks done.
- The products that are installed.
- The menu options that are omitted because of a `PRODUCT DISABLE` statement in IFAPRDxx, or because of an unauthorized higher level menu option.
- The content of the NLS table with the NLS option with the NLS option replaced by '-' if it is not authorized.

To check action character processing, you can add a `DEBUG ACTION` statement to the preamble. This statement causes debug output for each action character to be written to the SYSPRINT file.

Support for RACF group administrators

zSecure provides support for two types of decentral administrators: group-SPECIAL administrators and decentral administrators using the CKGRACF authorized component. The program can be run so that group-SPECIAL or decentral administrators will only be able to select and display the RACF resources and profiles within their scope. In this manual, this mode of operation is called *restricted* (or less correct, *PADS mode*). Use of this option can require special zSecure configuration options, see the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*. (The options are: PADS access to the RACF database, or restricted mode set in the CKRSITE module.)

Restricted mode can be simulated by using the SIMULATE RESTRICT command. If you include this command in your preamble (option **SE.3** from the Security zSecure menu), the program always runs in restricted mode. You can simulate restricted mode for the duration of one output list by using the NEWLIST SCOPE parameter.

When the program operates in restricted mode, a number of limitations apply and a number of commands and parameters cannot be used. These restrictions are described in the explanations for using the commands and parameters and in the command and parameter descriptions. The documentation also indicates which commands and parameters cannot be used in restricted mode.

When zSecure is operated in restricted mode, use is made of a RACF simulation engine in the product. Your local security policy might not allow you to perform *real* access control decisions based on a RACF simulation, rather than by calling RACF itself.

You can use restricted mode for your group-auditors. In restricted mode, any user is only able to select and display those SMF records relating to users or resources in his scope. Use of a CKFREEZE file is required.

Use in PADS mode

When zSecure is used in PADS mode (for example, installation-determined restricted mode, not simulated using SIMULATE RESTRICT or NEWLIST SCOPE, and not set in the CKRSITE module), a number of additional limitations caused by RACF Program Access to Data Sets apply.

- You must run the program from a 'clean' environment. This can be accomplished by running C2R (or the local copy that your installer prepared) before you start ISPF. More information on PADS mode is in the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.
- You cannot operate in split-screen mode.
- You can only use program controlled STEPLIBs and ISPLLIBs. You cannot concatenate your own unauthorized libraries.

Commands not allowed in restricted mode

In restricted mode, all commands which might influence the outcome of a simulated access control decision are flagged as errors. This means that the following commands and options cannot be used:

- DEBUG except for PERFORM, RESTRICT, CPIC, ACTION, DICT, OUNIT.
- LIMIT ID and LIMIT OLD
- LIST (only forbidden with NEWLIST TYPE=RACF or outside the scope of a NEWLIST)
- NEWLIST NOEGN, NEWLIST EGN, NEWLIST SCOPE
- PRINT NOEGN, PRINT EGN
- REPORT AC1, REPORT SCRATCH, REPORT PADS, REPORT STC
- SELECT/EXCLUDE outside the scope of a NEWLIST, except when only the QUAL parameter is used. When SELECT/EXCLUDE is used within the scope of a NEWLIST, access to certain fields is prohibited.
- SHOW CLASS
- SIMULATE SETROPTS
- SUPPRESS ICHCNX00, SUPPRESS CKFREEZE (only forbidden with NEWLIST TYPE=SMF).
- SIMULATE TODAY
- UNLOAD (only forbidden with NEWLIST TYPE=RACF or outside the scope of a NEWLIST).

A number of additional restrictions apply to interactive use with ISPF:

- The REPORT and VERIFY panels only allow the use of the QUAL selection parameter. All other selection parameters cause an error.

Other limitations:

- When you use REMOVE to delete a user or group within your scope, only the access list entries within your scope are deleted. This causes orphan permits for all access list entries outside of your scope. Security zSecure generates REMOVE commands to remove connect group entries; these REMOVE commands can cause RACF to issue error messages. The DELUSER command removes the connect entries left over.
- All unprotected data sets (UACC of READ or higher) are visible. In this, Security zSecure simulates RACF. Use QUAL (REPORT, VERIFY) or a mask (DISPLAY) to view only those data sets that you are interested in.
- To get FIELD profile support, a single class and segment name must be implied by the SELECT statement.
- Segments are shown only if there is at least one field on the display/sortlist statement that the user has READ access on through the FIELD class.
- When using indexed I/O, only FIELD profiles with a non-generic class and segment name prefix are consulted.

Access allowed in restricted mode

In restricted mode, the profiles that can be selected or displayed must be in the scope of the user (for example, owned directly or indirectly, or within the CKGRACF-defined scope), or must have a UACC of READ or higher. These restrictions have been based on RACF's access decisions in ICHUT100, IRRUT100, and the LISTDSD, RLIST, and SEARCH commands: some fields require profile ownership (directly or indirectly), some fields require audit authority. Access to masked fields is not allowed.

Scoping support for non-base segments based on FIELD profiles is performed. This means formatting the fields on DISPLAY and SORTLIST statements when the user has READ access or higher on the corresponding FIELD profile, and showing modifiable fields on a DISPLAY when the user has UPDATE access or higher on the corresponding FIELD profile. For restrictions, see the previous section.

To use restricted access mode, you must either have the system-wide special or auditor attribute, or the RACF database processed must contain the userid you use to run CKRCARLA with. Your access to masked fields is determined by the authority of your userid. The following table shows the field and profile access restrictions in the four cases:

Table 635. Restricted mode: Field and profile access restrictions

Userid Authority	Access restriction
Auditor	Access to masked fields not allowed.
Special	Access to masked and global audit fields not allowed.
Group-auditor	Access to masked fields not allowed. Access to non-base segments is not allowed. Access to global audit fields not allowed except in scope of ownership. Profiles are hidden unless at least READ access. Access to access list and security level/label/category information not allowed outside scope of ownership.

Table 635. Restricted mode: Field and profile access restrictions (continued)

Other	Access to masked fields not allowed. Access to non-base segments is not allowed. Profiles are hidden unless at least READ access. Access to access list and security level/label/category information not allowed outside scope of ownership. Access to USR fields limited by the CKGRACF-defined USRDATA scope.

Support for RACF group auditors

To provide support for group-auditors, the SMF functions of Security zSecure can be used in so called *restricted mode* . Also, see the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide* for an explanation of restricted mode and its consequences.

Restricted mode can be in effect due to:

- Use in PADS mode , because access to the RACF database, unloaded database, CKFREEZE file, or SMF input files was granted through Program Access to Data sets, implemented as a conditional access list.
- Use of the SIMULATE RESTRICT command.
- Use of the SCOPE parameter on the NEWLIST command. In this case, the restrictions apply to the affected NEWLIST only. This only works for the SMF NEWLIST.
- A setting made in the CKRSITE module.

In restricted mode, users can only select (and display or unload) those SMF records that are in their scope. Users are allowed to see records that:

- Describe users or actions of users that are in their scope, e.g. the users owned by a group administrator. This includes the group-administrator scope defined for the CKGRACF authorized component of zSecure.
- Describe a resource that is in their scope, e.g. a data set that is owned by the user. Both data sets and general resources are supported.
- Describe a data set that is not protected (only if the system does not have ADSP or PROTECTALL(FAIL) active). Unprotected data sets are those data sets that do not have a RACF profile (discrete or generic) to protect the data set. Data sets with a UACC of READ or higher are not treated as unprotected, and are *only* visible within the user's scope.

  The visibility of unprotected data sets can be suppressed using the SUPPRESS NOPROFILE command. If this command is given, SMF records that describe an unprotected data set outside the user's scope, are not shown.

Restricted mode for the SMF processing functions of zSecure is subject to the following limitations:

- Like the restricted mode of zSecure, system-wide SPECIAL, OPERATIONS or AUDITOR is not supported in the scoping rules, but group-SPECIAL, group-OPERATIONS and group-AUDITOR is. Use restricted mode for group-administrators only.
- SMF records for which no RACF userid, RACF profile, or data set can be found can only be selected in unrestricted mode. Typically, these records describe system-wide events or status.
- The SUPPRESS CKFREEZE command is ignored, because CKFREEZE data is required to find the correct profile for data sets. The SUPPRESS reasons other than SUPPRESS NOPROFILE do not work for SMF records.

Limitations of the RACF simulation

Most VERIFY and REPORT commands are based on a simulation of the RACF access control decisions (simple LIST and DISPLAY commands are not). This simulation currently has a number of restrictions. The following RACF features are not considered in the access control simulation:

- Security levels, categories, and SECLABELs. In short, Mandatory Access Control is not yet supported (except in the COPY command).
- DASDVOL authority is not yet taken into account for access to DASD data set resources.
- The action of site-specific RACF pre- and postprocessing exits cannot be simulated. The only exit that can be handled successfully is ICHCNX00. This exit is called with a code indicating that it is ICHUT100 calling the exit. Experience shows, that not all customers using this exit have included support for ICHUT100 in their exit, and consequently zSecure also misses the support. Some sites depend on authorized features (zSecure calls the exit in an unauthorized environment), or use the current user's ACEE.
- Structural errors in the RACF database. If the IRRUT200 checks find errors, zSecure can report on profiles that cannot be found through RACF commands.

The Naming Convention Table ICHNCV00

zSecure supports the RACF Naming Convention Table ICHNCV00. A limited subset of ICHNCV00 functionality is supported in the simulation by zSecure. (Note: These programs are able to display any legal ICHNCV00 table properly, including those functions not supported by the simulation.)

In the current implementation, the following ICHNCV00 features are supported:

- Interpretation of ICHNCV00 per system; each system can have its own version of the table. For RACF reporting, the default system's ICHNCV00 is used to report on shared systems. For SMF reporting, the actual system table (as indicated by the CPU id in the SMF record) is used.
- Proper flow control using the NEXT parameter.
- SELECT and ACTION clauses using the GQ, UQ, and QUAL variables, and both numerical and literal constants. Up to 22 qualifiers with a length of up to 8 characters each are supported. Support for longer qualifiers, as used by some installations for tape data set name conversions, could be added on request.
- Subscripting of GQ and UQ using numerical subscripts. (Using implicit subscripts, or using variables as subscripts, is not currently supported.)
- Substring operations on the GQ, UQ, and QUAL variables, both in SELECT clauses and in ACTION clauses.
- SELECT clauses using RACUID, RACGPID, RACUID3, and RACGPID3. Support for this feature is limited, and always assumes a different user's and group's data set is used. In effect, this implies that comparisons using RACUID, RACGPID, RACUID3, and RACGPID3 will never match.

Restricted support is provided for the following ICHNCV00 features:

- SELECT clauses using the EVENT variable support only the RACHECK event code (X'0100').
- SELECT clauses using the VCT variable support only values of 0 (no volume specified) and 1 (one volume specified).
- SELECT and ACTION clauses using the VOLUME variable support only 1 (one volume) in VOLUME array.

- SELECT and ACTION clauses using the VOLUME variable is not supported for VSAM data sets; warning message CKR0850 is issued and no conversion takes place.
- SELECT and ACTION variables using QUAL variable also ignore the VOLUME specification; if a volume value is specified, it is ignored.

The following ICHNCV00 features are not supported:

- SELECT and ACTION clauses using any variable types other than GQ, UQ, QUAL, RACUID, RACGPID, RACUID3, and RACGPID3. Specifically, the following variable types are not supported: G, U, QCT, NAMETYPE, V, OLDVOL, WKX, WKY, WKZ, WKA, WKB, WKC.
- Data set names with more than 22 qualifiers, or with qualifiers of length zero or a length greater than 8.
- Implicit subscripting of GQ and UQ, or subscripting of GQ and UQ using variables.

SMF processing - Background

This section describes some internals of SMF processing.

At the end of each run, zSecure provides an overview of the range of records processed. For each system, the date and time of the earliest record processed and the date and time of the last record processed are shown. The sample output that follows shows the layout of the record overview:

```
CKR0452 00 SMF records were processed for the following systems:
           System ML1E from 23 Aug 1994 02:54 to 23 Aug 1994 05:10 (no CKFREEZE file)
           System ML1S from 30 Aug 1993 04:11 to 30 Aug 1993 04:14 (no CKFREEZE file)
```

Figure 528. Overview of records processed

The record overview displayed in the preceding figure does not include the date and time of SMF record types 2 and 3. These records do not describe system events, but are created by the IFASMFDP program and indicate the start time and end time of the IFASMFDP run, which is always later than the last SMF record dumped.

The date and time of the earliest and last records processed, across all systems, is also displayed in the report header.

Special processing is also performed for SMF record type 7, which indicates that SMF data was lost on the system that generated the SMF records, presumably because the SMF buffers were full. The events that occurred during the period that the SMF buffers were full are lost, and cannot be audited using SMF. zSecurebrings this to your attention using message CKR0461. (The zSecure messages are documented in *IBM Security zSecure: Messages Guide*.). The following sample shows message CKR0461:

```
CKR0461 00 48059 SMF records were lost on system  from  5 Feb 1994 00:10
```

Figure 529. Sample message CKR0461

Class, resource and profile

This section documents the way zSecure handles RACF classes, resources and profiles for the NEWLIST TYPE=SMF.

Derivation of class, resource and profile

Most RACF processing records (SMF record types 80 and 83) contain information on the class, resource, and profile processed. Most non-RACF records do not contain this information. Instead, some of these records describe data sets, from which RACF profile information can be derived. zSecure attempts to derive RACF class, resource, and profile information for data set and catalog activity records, and HSM function statistics records. It handles this in the following manner:

- The data set name is used to derive the RACF resource name. Temporary data sets are discarded: no resource name is found. For VSAM data sets, a `CKFREEZE` file might be required to find the resource name.
- The resource name is used to determine the profile name; zSecure uses the RACF database to achieve this.
- If a resource or profile name can be found, the class is set to DATASET; it is not set otherwise.

While most RACF processing records contain class, resource and profile fields, some do not. zSecure handles the exceptions in the following manner:

- The class for the RACINIT, ADDUSER, ALTUSER, CONNECT, DELUSER, PASSWORD, and REMOVE events is set to USER. The target user from the record is used as resource and profile.
- The class for the ADDGROUP, ALTGROUP, and DELGROUP events is set to GROUP. The target group from the record is used as resource and profile.
- The class for the ADDSD, ALTDSD, and DELDSD commands is set to DATASET. The resource and profile are taken from the record.
- For DEFINE events of class <>DATASET, generic profiles cannot be derived if not included in the record.
- For GENERAL events written by the CKGRACF authorized component of zSecure, the class, resource, and profile are taken from the LOGSTR field.

Example of profile derivation

As an example of the way zSecure derives the RACF information from an SMF record, let's study the fields derived for some sample RACF commands.

Assume that user USERAA, while connected to group GROUPBB, issued the command 'CONNECT XX GROUP(YY) OPERATIONS'. In that case, the following fields are set:

Table 636. Profile derivation sample field settings

Field	Value	Explanation
CLASS	USER	The class of the target profile.
EVENT	CONNECT	The event is a CONNECT command.
GROUP	GROUPBB	The current connect group of the command-issuing user.
PROFILE	XX	The target profile: user XX.
RACFCMD	CONNECT XX GROUP(YY) OPERATIONS	The full RACF command issued.
RACFCMD_GROUP	YY	The target group of the RACF command.
RACFCMD_KEYWORDS	GROUP OPERATIONS	The keywords used in the RACF command.

Table 636. Profile derivation sample field settings (continued)

Field	Value	Explanation
RACFCMD_USER	XX	The target user of the RACF command.
RESOURCE	XX	The target resource.
USER	USERAA	The command-issuing user.

If user USERAA were to issue the command DELGROUP ZZ instead, the following fields would be set:

Table 637. Profile derivation sample field settings

Field	Value	Explanation
CLASS	GROUP	The class of the target profile.
EVENT	DELGROUP	The event is a DELGROUP command.
GROUP	GROUPBB	The current connect group of the command-issuing user.
PROFILE	ZZ	The target profile: group ZZ.
RACFCMD	DELGROUP ZZ	The full RACF command issued.
RACFCMD_GROUP	ZZ	The target group of the RACF command.
RACFCMD_KEYWORDS		No keywords were used in the RACF command.
RACFCMD_USER		There was no target user of the RACF command.
RESOURCE	ZZ	The target resource.
USER	USERAA	The command-issuing user.

To summarize:

- Use the EVENT field to select specific RACF command types.
- Use the CLASS and RESOURCE fields to select the main target resource; this works for both RACF and non-RACF records.
- For user and group profiles, the RESOURCE and PROFILE fields are identical; for data set and general resource profiles, the RESOURCE field is the 'real' resource (e.g. actual data set name), while the PROFILE field can be a generic profile (e.g. 'SYS1.**').
- Use the RACFCMD or RACFCMD_KEYWORDS field to select commands using specific keywords and options.
- The RACFCMD_USER and RACFCMD_GROUP keywords can be useful to select the targets of a RACF command; in most cases, an alternative is 'SELECT CLASS=USER RESOURCE=XX'.

Use of the CKFREEZE file

zSecure can use a CKFREEZE file with catalog information to determine the resource and profile name for a VSAM data set. This is required to find the resource and profile for SMF record type 62 (some instances), type 64 (all instances) and HSM function statistics records (some instances). If no CKFREEZE file for the system is available, resources and profiles can only be found for VSAM cluster names.

zSecure always tries to read a CKFREEZE file if the CLASS, PROFILE, or RESOURCE fields are used; if this is not desired (e.g. if only RACF processing records are of interest), use the SUPPRESS CKFREEZE command.

Note: zSecure Collect, the program used to create a CKFREEZE file, does not collect VSAM path names by default. To do this requires the ALLRECS parameter in zSecure Collect. In either case, zSecure is currently unable to find resource and profile names for these data sets.

The job tag system

This section documents the way in which zSecure attempts to complete some job-related records with security package user and group information.

One of the features of zSecure is a job tag caching system; it allows zSecure to supply RACF and ACF2 userids, group ids, terminal ids and job ids for several SMF record types that do not contain this information themselves. This is accomplished by collecting all *job tags*, for example, the information that uniquely identifies a job. If the userid, group id, terminal id and job id can be found for this job tag, all other SMF records for that job can be completed with this information.

To make this system really useful, a *record cache* has been introduced. If a record is found that cannot be completed, it is stored. Processing of this record is delayed until the record can be completed or until all the input files have been exhausted. Because this feature can require a lot of memory, use the `SMFCACHE` command to limit the amount of cached records. Some record types are not cached. For those records, the missing fields are only completed if the value of these fields is obtained before the non-cached records are processed.

The job tag caching system, if active, causes the following record types to be cached and/or completed:

Table 638. Job tag system - record types to be cached or completed

Type	Description	Cached	Completed fields
14	Input Activity	Yes	All
15	Output Activity	Yes	All
17	Scratch Data Set Status	Yes	All
18	Rename Data Set Status	Yes	All
20	Job initation	No	JOBID
60	VSAM Data Set Updated	Yes	All
61	ICF Define Activity	Yes	All
62	VSAM Component or Cluster Opened	Yes	All
64	VSAM Component or Cluster Status	Yes	All
65	ICF Delete Activity	Yes	All
66	ICF Alter Activity	Yes	All
80	Racf processing	No	JOBID
83	Racf audit for data sets	No	JOBID

Table 638. Job tag system - record types to be cached or completed (continued)

Type	Description	Cached	Completed fields
92	UNIX file system activity	No	JOBID, TERMINAL

The job tag information is collected from record types 30 and 32; the job tag from any job-related record can be printed using the JOBTAG field.

Several limitations to the use of the job tag system exist. The two most important are multi-user address spaces and system address spaces. Multi-user address spaces might be a problem because RACF and ACF2 processing records might indicate the user on whose behalf an action is performed, while the job tag system indicates the user ID and group ID for job start and end records. In this case, the completed records have the address space's user ID and group ID rather than the user ID and group ID of the user causing the record to be written. Examples of such multi-user address spaces are Roscoe and FTP. System address spaces often cannot be identified uniquely. For example, address spaces that have a job name containing zeroes and the job start date and time that are also zero cannot be distinguished from one another. Because of this, records for system address spaces are ignored by the job tag system.

When your system has some long-running jobs that generate records, and you want these to be completed by the job tag system, you might have to turn on interval accounting. This option prevents the job tag system from being swamped with records that have incomplete job tags. An interval of half an hour to an hour is usually sufficient. Turn off detail recording to prevent huge CPU and I/O loads. For more information, see the information on the `SMFPRMxx`, `NODETAIL` parameter the *MVS Initialization and Tuning Guide* for more information. Use the `SMFCACHE VERBOSE` command to obtain statistics on memory usage and the amount of records cached or skipped for specific jobs.

CKGRACF Restrictions

CKGRACF has the following restrictions:

- The USR field of discrete data set profiles is not supported, see “USRDATA” on page 1554.
- If class FACILITY is used, profile keys are limited to 39 characters. The resource name checked can be up to 255 characters; however, because of the length restrictions, you might not be able to create a discrete or generic profile to fit a scope resource name checked (CKG.SCP.U... or CKG.SCP.G...).
- RACF password synchronization does not support modifications made through CKGRACF.

  RRSF propagation of CKGRACF changes can fail (with a message IRRR116I, processing code 506) if too many schedules and/or queued commands are present in the profile. Both active entries and those kept in the audit trail count towards this limit. For example, changes to USER profiles with more than 33 schedule commands with both a start and end date cannot be propagated.

  Propagation fails because the CKGRACF USRDATA becomes too long to fit into a command of 5000 bytes, which is the biggest command RRSF can propagate. The problem profile can be fixed by removing CKGRACF USR entries from it that are no longer needed with the WIPE command. See “WIPE” on page 1558, possibly followed by re-adding still relevant entries.

If the problem occurs for more than one profile, or if it re-occurs on a regular basis, the period during which CKGRACF keeps expired commands in the profiles for auditing purposes might be too long. This setting can be verified with the SHOW CKRSITE command. See "SHOW" on page 1529. If changes to this setting are needed, see the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

Chapter 16. zSecure Collect for z/OS

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•	•	•	•	•	•	

The zSecure Collect program, CKFCOLL gathers information about your z/OS system configuration. The program is designed to collect data quickly using minimal system resources. The data collected is analyzed by the CKRCARLA program.

To get a complete picture of your I/O subsystem, zSecure Collect must be run on all systems using shared DASD. The data can be used to provide a mapping between the physical target of I/Os on DASD and the named entity. The physical target of I/O operations can be any of the following hardware components: control unit, physical disk, cylinder, or track. The named entity is known to the user or operating system through one of the following identifiers: Device number, volume name, data set, file, data space, or PDS member). This information is necessary to perform various tasks such as:

- Matching resources (volumes, data sets, VSAM clusters) to (generic) profiles in RACF.
- Auditing the system protection by collecting information including but not limited to the following types:
  - current RACF options
  - RACF data set names
  - APF data set names
  - `LINKLIST` concatenation data sets
  - LPA list data sets
  - in-storage MLPA and PLPA members
  - page and swap data sets
  - SMF, JES2, HSM, CA1, and DMS data sets
  - SMF recording activity and exits
  - actual PPT contents
  - actual TSO command table contents
  - contents of APF data sets (AC=1 module information)
  - JES2 STC and TSU Procedure Library (`PROCLIB`) directories
  - SVC data
  - Program Call data
  - Subsystem data
  - JES2 data
  - exits
- Auditing system change. Checksum values can be computed for data sets both at member and data set level.
- Creating a system definition file for EREP (Environmental Record Editing and Printing Program), mapping errors on shared DASD to the same device (error counter).
- Creating CONFIG*xx* members for comparison between configurations.

zSecure Collect does not perform any of these functions, it only collects the data required to perform the functions. The zSecure Collect function is like the DCOLLECT function. However, the DCOLLECT function does not collect enough data to perform the resource matching, auditing, comparison, and other functions described. Consequently, you cannot use this function in place of zSecure Collect.

Other than some messages and a summary report, the zSecure Collect program does not provide reporting functions because it is designed to use minimal resources. Data analysis is done by the CKRCARLA program. You can also write your own post-processor for the collected data.

See the following topics for more information about zSecure Collect:

- "Understanding the key components of zSecure Collect"
- "Getting Started" on page 1594
- "Configuring zSecure Collect" on page 1594
- "Starting zSecure Collect" on page 1602
- "zSecure Collect command reference" on page 1612
- "zSecure Collect reports" on page 1604
- "Troubleshooting" on page 1635

Understanding the key components of zSecure Collect

When you use zSecure Collect, you need to be familiar with the following components:

- JCL to run zSecure Collect
- Input sources and the parameters
- Messages and reporting

JCL to run zSecure Collect

The SCKRSAMP library contains sample JCL to run zSecure Collect. When IBM Security zSecure has been installed and enabled, zSecure Collect can be used immediately in non-APF mode. For operations requiring APF authorization, you have to obtain a permit to the proper resource. See "Deciding whether to run APF-authorized" on page 1601 for a discussion on setting up zSecure to run with APF authorization. If you are trying out zSecure Collect for the first time, you do not need APF authorization.

Figure 530 provides sample JCL that enables data collection for zSecure Audit for ACF2, one of the products supported by zSecure Collect:

```
//CKFCOLL  EXEC PGM=CKFCOLL,PARM='FOCUS=AUDITRACF',
//         REGION=64M
//SYSPRINT DD SYSOUT=*
//CKFREEZE DD DISP=(,CATLG),DSN=userid.name.CKFREEZE,
//            UNIT=SYSDA,
//            SPACE=(32760,(1000,1000),RLSE,,ROUND)
```

Figure 530. Sample JCL to collect data for zSecure Audit for ACF2

For additional information about running zSecure Collect, see "Starting zSecure Collect" on page 1602.

Input sources and parameters

zSecure Collect can take its input from the parameter string in the JCL(PARM)statement, the SYSIN file, or both. However, neither of these sources are required. The zSecure Collect parameters and commands are used to

determine what information is collected along with other processing options. The most important parameter is the FOCUS parameter which specifies what data is collected. For example, if you specify the parameter value `FOCUS=AUDITRACF`, zSecure Collect collects data for zSecure Audit for ACF2 for RACF.

If you have the appropriate entitlements for the products, you can specify as many options as you want for the `FOCUS` parameter. The entitlements are defined in the `IFAPRD`*xx* `parmlib` member. If you do not specify any options, zSecure Collect assumes all focuses that are installed and enabled in `IFAPRD`*xx*. This default behavior means that zSecure Collect collects all data for all enabled products. If your site only uses one of the zSecure products installed, you can specify the `FOCUS` for that product explicitly. This reduces the time required for data collection time. See "Selecting the products for the collect operation" on page 1595.

For additional information about the zSecure Collect parameters and commands, see "Configuring zSecure Collect" on page 1594 and "zSecure Collect command reference" on page 1612.

Messages and reporting

zSecure Collect generates messages and one report. To understand the output data, you can review the `CKFREEZE` output. The CKFCOLL output is in a spanned variable blocked file with different kinds of records. You do not need to understand the file layout because the CKRCARLA program reads the data and processes it for you.

The `SYSPRINT` file is likely to contain messages stating that information could not be collected or is missing. These messages do not cause problems for the configuration analysis. However, the messages can be helpful to debug problems. Some messages, like `CKF017I` can be a nuisance. To suppress these types of messages, add the command `SUPMSG=17`.

Figure 531 on page 1594 provides an example of output from an authorized run. Some pages have been omitted from the sample output.

Figure 531. zSecure Collect sample output

Getting Started

To run zSecure Collect, you need to configure the program and then start the collection process. Before beginning the configuration process, review "Understanding the key components of zSecure Collect" on page 1592 for an overview of the zSecure Collect program. For instructions, see the following sections:

- "Configuring zSecure Collect"
- "Starting zSecure Collect" on page 1602

Configuring zSecure Collect

The zSecure Collect program supports several types of commands that help manage program operation and customize the amount and type of data collected. For more information, see the "zSecure Collect command reference" on page 1612. See the following topics for information and instructions for configuring zSecure Collect.

- "Managing program operation using environment variables."
- "Selecting the products for the collect operation"
- "Using APF-only parameters to restrict some APF-authorized collection" on page 1597
- "Setting the collect parameter options (Feature=)" on page 1596
- "Specifying alternate data sources" on page 1597
- "Restricting information collection using SELECT and EXCLUDE commands" on page 1598
- "Reducing disk space required for data collection" on page 1600
- "Verifying the operating system where zSecure Collect runs" on page 1601.
- "Deciding whether to run APF-authorized" on page 1601.
- Specify general options such as `CAPS` and `REPORT`. See "zSecure Collect command reference" on page 1612.

Managing program operation using environment variables

You can use the `IF`, `APF`, and `EXIT` commands to manage the operation of zSecure Collect. For example, you can stop the run if the program is not APF authorized, or if the job is run on an unintended system. You can use the `IF`, `APF`, and `EXIT` commands to stop the run when the program is not APF authorized. It also stops the program if the job is run on an unauthorized system. You can even tailor the exact parameters used in the run based on the static system symbols defined on the system.

Selecting the products for the collect operation

The information collected is determined by the *focus* explicitly selected using the `FOCUS` parameter, or implied by the products installed and the `PRODUCT` statements in `IFAPRD`*xx*. Based on these specifications, some information is collected by default. You can also specify additional parameters to change the default collection process or to collect additional information. To use a specific `FOCUS`, the following prerequisites must be fulfilled:

1. The corresponding product must have been purchased and installed.
2. The product must not be disabled in PARMLIB member `IFAPRD`*xx*.
3. If zSecure Collect is running APF-authorized, you must be *permitted* by the System Authorization Facility (SAF) to use each of the focuses specified. SAF can return three levels of authority: *access allowed*, *access unexplained*, and *access prevented*. You must be explicitly authorized to access the `CKF.`*`focus`* resources in the CKRSITE-defined class corresponding to the selected focuses. There are exceptions to this rule: `TSIEM` and `ALERT` SAF authorizations are not needed if the `AUDIT` focus is also requested. `VISUAL` SAF authorization is not needed if RACF focus is also requested.

The focus can be specified by the parameter `FOCUS`. If it is not specified, the value defaults to the products that have been enabled. If you have only one product for which zSecure Collect gathers data, you can omit the parameter. The exception to these focus rules is for the zSecure Alert product. If you have this product, you must always explicitly specify `FOCUS=ALERT`.

Figure 532 on page 1596 provides an overview of the default settings–dependent on APF status, and supported features for each focus.

```
Y - Default =YES and allowed to specify =NO
. - Default =NO or 0 and NOT allowed to specify another value
n - Default =NO  and allowed to specify =YES
v - Default =0   but value specification is allowed

Figure 532. Features allowed by focus type (focus = product code)

Use the column corresponding with the first part of the focus name (for example, use the AUDIT column for AUDITRACF).

Setting the collect parameter options (Feature=)

To control the type of information to be included, feature selection commands are available. These commands are of the type *feature*=YES/NO. Most of the features are only valid under specific focuses. Specification of YES if the focus does not entitle the feature results in error message CKF134I. You can also specify NO independently of the current focus and serves to suppress collecting data of the specified type.

The features are more or less *hierarchical*. If some features are set to *NO*, it implies the NO setting for a number of features at a lower hierarchical level. This propagation is done after all input has been read and all IF statements have been processed. Figure 533 on page 1597 lists the dependencies for the zSecure Collect feature selection commands. For complete documentation on the zSecure Collect commands, see “zSecure Collect command reference” on page 1612.

Figure 533. Feature selection commands - dependencies

Using APF-only parameters to restrict some APF-authorized collection

These following options are primarily meant to aid in problem determination and problem circumvention during APF-authorized runs: `NOSIO`, `NOBYPASS`, `UNCONNECTED`, `NOKEY0`, `NODIAG`, `NOUID0`, `NOXMEM`, and `NOXMDSN`. For details on these parameters, see "zSecure Collect command reference" on page 1612. All options specifically disable some APF-authorized ways of obtaining information. Generally, you do not need to specify any of them.

Specifying alternate data sources

These options are meant to select the data set names of additional data sources. For example, these options are used for selection when you have more than one HSM or DMS system active, when you need additional PDS directories, or when zSecure Collect fails to determine the required data set name automatically. Automatically generated data set names requires access to all data sets. Data set names specified manually, using the data source parameters only require access to the SAF resource if the program is running APF-authorized. However, *manually* coded data set names do require a READ access on the data set with one exception: With access to the SAF resource, zSecure Collect can dump any PDS directory without having access to the data set.

You can use the following alternate data source parameters to specify data set names: PDSDIR, ICFCAT, HSMMCD, HSMMCDS, HSMBCD, HSMBCDS, DMSFILES, DMSUNL, DMSPARMS, TMCDSN, RMMCTL, ARCDSN, VMFDSN, CHECK, and CHECKDSN.

If no explicit volser has been supplied for these alternate data sources, they might not be found if the volume does not get processed for other reasons. To ensure that the data sources can be found, you can specify the RECALL=YES setting. This option explicitly allocates all data sets with an unknown volser, but also recalls migrated data sets. Or, you can specify the VTOC=YES setting which forces the program to read all volumes in order to dump their VTOCs.

Restricting information collection using SELECT and EXCLUDE commands

The SELECT and EXCLUDE commands can be used to select data on either the device or volume level and on the data set level. You can use the SELECT and EXCLUDE commands to reduce the number of records written to the CKFREEZE file commands by including or excluding information by *device* or *volume* or by *data set level*. These commands can only be used to reduce the number of records written to the CKFREEZE file. They cannot be used to select extra records beyond the selections implied by the FOCUS parameter settings and other zSecure Collect options.

You can use one or more SELECT and EXCLUDE commands to restrict data collection. Multiple SELECT statements on the same level imply an *inclusive or* function. For each selection level, the commands are processed in the following sequence.

1. Select commands are processed first.
   - If a SELECT command is present and the selection criteria of all SELECT commands *fail*, the current candidate is skipped and no further processing is performed.
   - If the SELECT options are met, any EXCLUDE options present are processed.
   - If all the EXCLUDE commands fail, the current candidate is selected and is included; otherwise it is skipped.
2. EXCLUDE commands are processed next.

   If all the EXCLUDE commands fail, the current candidate is selected and included; otherwise the candidate is excluded.

Use the following base syntax to specify the SELECT and EXCLUDE commands. Use these commands with the device or data set level options as required.

SELECT= *list*
SEL=*list*
S=*list*
The SELECT command accepts a list of selections enclosed in parentheses and separated by commas. If only one selection option is needed, the parentheses can be omitted. The selections in the list indicate an AND condition if they are on the same level; multiple commands indicate an OR condition.

EXCLUDE= *list* **EXCL=***list* **X=***list*
The EXCLUDE command accepts a list of selections enclosed in parentheses and separated by commas. This syntax applies to all commands with more than one format. If only one selection option is needed, the parentheses can be omitted. The selections inside the list indicate an AND condition if they are on the same level; multiple commands indicate an OR condition.

For details on how to use these commands to restrict the data written to the CKFREEZE file, see the following sections:

- "Selecting data by device or volume"
- "Selecting data by data set level"
- "Examples of device and data set level selections" on page 1600

Selecting data by device or volume

Use the following options for selecting or excluding data at the device or volume level. For examples, see "Examples of device and data set level selections" on page 1600.

Device/volume level selection options

CH= *xx*
CHP=*xx*
CHANNEL=*xx*
C=*xx*
Restricts selection to the devices on a specified (physical) channel (path). The channel must be specified as two hexadecimal digits.

VOLUME= *xxxxxx*
VOLSER=*xxxxxx*
VOL=*xxxxxx*
V=*xxxxxx*
Restricts selection to the devices which have a volume serial starting with the specified string. The value can be 1 - 6 characters long.

DEV= *xxxx*
DEVICE=*xxxx*
UNIT=*xxxx*
U=*xxxx*
Restricts selection to the devices which have a device number starting with the specified string (1 - 4 hexadecimal digits). Both 3 and 4 character names are checked. For example, U=123 would select device 123, 0123, 1230, 1231, 1232, and so on.

STORGRP= *xxxxxxx*
SG=*xxxxxxx*
Restricts selection to the devices belonging to the specified storage group (1 - 30 characters).

LCU= *xxx*
Restricts selection to the devices which are members of the specified logical control unit. This parameter applies to MVS/XA and MVS/ESA sites not running under VM. The LCU number of a device group is available from RMF reports and IOCP reports. The LCU must be specified as 3 hexadecimal digits, or as a prefix for LCU names of 1 or 2 hexadecimal digits.

Selecting data by data set level

For the devices selected through device level selection, the data set level selection regulates which records are to be dumped. See "Selecting data by device or volume." Data set specific records are only written if they match any data set selection criterion that has been specified. For example, only VTOC, VVDS, ICF catalog, and HSM MCDS and BCDS records are dumped for the specified data set. If you want to dump information contained in a data set, use options like `PDSDIR` or one of the options ending in DSN, like `CHECKDSN`. Use these options instead of the `SELECT=DSN=` specification.

Use the following options when selecting data by data set level. For examples, see "Examples of device and data set level selections" on page 1600.

DSNHLQ= *list*
The DSNHLQ command accepts a list of HLQs, enclosed in parentheses and separated by commas. If only one HLQ is needed, the parentheses can be omitted. This option can be used to select or exclude data sets that have an HLQ specified in the list.

DSN= *prefix* **DSNPREF=***prefix* **D=***prefix*
Restricts selection to the data sets that have a name starting with the specified string. This option is like the DSNHLQ option. The use of DSNHLQ is preferred to DSNPREF, especially since it is much faster with larger selections.

Examples of device and data set level selections

For examples of device and data set level selections, review the following code examples.

An example of a selection option to collect information for one LCU only:

```
SELECT=LCU=005
```

The same example, but excluding a specific volume giving problems:

```
SELECT=LCU=005
EXCLUDE=VOL=DISK12
```

An example to select a number of volumes based on their prefix, abbreviated as much as possible (logical OR):

```
S=V=SSD
S=V=SHR
```

An example to select a number of volumes based on both their volume serial prefix and their SMS storage group (logical AND):

```
SEL=(VOL=OVFL,STORGRP=PRIMARY)
```

An example of a selection option to collect information for all data sets with HLQs SYSS, SYSP, and SYSQ:

```
S=DSNHLQ=(SYSS,SYSP,SYSQ)
```

Reducing disk space required for data collection

`CKFREEZE` data sets can become large because of the amount of data collected. You can conserve disk space and reduce CPU processing time) by turning off `CKFREEZE` features that are not required for day-to-day tasks. You can also save disk space by using SMS compression for the `CKFREEZE` data set.

Disabling the following features can reduce the necessary disk space drastically. Disable these features when the resulting `CKFREEZE` records are not required for your daily tasks.

BCD=NO
The Backup Control Data set data is currently only used for determining if discrete data set profiles need to be removed. These discrete data set profiles are found in various AU.V - Verify functions and are reported in the RACF profiles report (RA.3.1). If you do not use any discrete data set profile or run the RACF profiles report often, you can disable this function.

This information is used in `VERIFY ONVOLUME` and `REPORT_PROFILE NEWLIST`.

UNIX=NO
UNIX data requires substantial amounts of disk space (all directories, owner

data, and file permissions are stored). UNIX data is used for TRUSTED reports, SENSITIVE data sets reports (HFS data set sensitivity), and auditing UNIX filesystems. SMF records pertaining to UNIX files often do not contain the path to the file, and the CKFREEZE information can be used to show the appropriate path. Without the UNIX data, most reports still give usable, though incomplete, results. When you are not auditing the HFS or zFS data sets, turn off this feature.

This information is used in the following NEWLIST types: UNIX, TRUSTED, REPORT_SENSITIVE, DSN, SENSDSN, and SMF.

SMS compression can also reduce the amount of disk space needed to store the CKFREEZE data sets. To use this compression, in SMS you must create a DATACLAS for the CKFREEZE data sets with COMPACTION option set to YES. Examine whether compressing the data sets improves overall performance. Reading a compressed data set uses less I/O but can require more CPU.

Verifying the operating system where zSecure Collect runs

The features included in zSecure Collect make the data heavily dependent on the operating system version in effect during the data collection. Check to see if you are running a current and supported release at http://www.ibm.com/software/support/lifecycle/index_a_z.html.

Older releases (including OS/390, MVS/XA and MVS/ESA but not MVS/370 and MVS/SP1) probably work for most options, but are no longer fully tested. The zSecure Collect program has been designed to tolerate changes in the operating system without ending the program. Instead of ending the program, some record types are left out if the program does not know how to find them. When this problem occurs, a message is sent to the user.

Deciding whether to run APF-authorized

zSecure Collect provides support for both authorized and unauthorized operation.

To run authorized, copy the program to an APF library and run from this library. You must also define the profiles or rules for the CKRSITE-defined class in your security system. This definition determines who can use which authorized functions through the System Authorization Facility (SAF). Unless sufficient authority is granted to the proper resource, the program refuses to operate with APF authorization. Access is authorized if RACSTAT returns *inactive* or *not installed*. If this problem occurs, a message is issued to indicate that no authorization checking was possible and why.

Callers that want to run the program without having access to the proper resource must drop the APF authorization. For example, authorization requirements can be dropped by running it from a non-APF library, or by including a non-APF library in the STEPLIB.

The program issues a message if it is run without authorization, to note the reason for missing information. Clearly, not all configuration information can be obtained if the program is run without authorization. Specifically, APF authorization provides the following benefits:

- DFSMS requires authorization to read the VVDS data set. The VVDS is used to report cluster names instead of system-generated names VSAM component names. The VVDS is required by IBM Security zSecure if VSAM data set protection has to be taken into account.

- DB2, CICS, and IMS data is obtained by zSecure Collect from the address space private region only if you are running zSecure Collect APF-authorized.
- The Communications Server requires APF authorization to read the TCP/IP stack configuration data.
- Security and integrity can be enhanced for zSecure Collect operations by removing the following requirements: Remove the `READ` access requirement to APF libraries for directory dumps. Remove the `ALTER` access requirement to APF libraries for dumping ICF catalogs. This function requires APF to bypass the data set protection and is authorized for all focuses that permit dumping these data sets.
- VM data is obtained only if you are running APF-authorized. This processing applies to all focuses.
- Information is obtained from the following sources: The JES2 address space provides information about the procedure libraries in use for started tasks and TSUs, the spool data set name, and parameter data set and member names. The HSM address space provides information about the migration and backup control data set names being used. Use of this function is authorized only if the ID in use is explicitly authorized to access the corresponding focus resource.
- Information is obtained from the JES2, HSM, and VTAM address spaces on the current setting of security sensitive parameters (like command authority and exits).
- Information is obtained from the RMF address space, for instance RMF release. Use of this function is authorized with all focuses.
- Information is obtained about TCP/IP stack configuration.
- Information is obtained about the CS Resolver configuration.
- A test is done to see whether the device is responsive before trying to allocate it. This check prevents volumes reserved by other operating systems from hanging. Use of this function is authorized with all focuses.

When any or all of the benefits of APF authorization are considered essential, you might want to specify the `APF` keyword. Specifying this keyword causes the program to end with a return code of `12` when authorization cannot be obtained. In addition, a `CKFREEZE` file is created with only a zSecure Collect identification record. Using the `APF` option saves considerable time and resources compared to the creation of a `CKFREEZE` that contains only limited data.

Note: As with any authorized program, it is recommended that you install the program on a test system first.

Starting zSecure Collect

You can start zSecure Collect by using the **F** (Refresh) transaction for the **Setup Input files** (**SE.1**) option. See Table 647 on page 1647. This transaction submits a job that runs zSecure Collect as a batch process. However, for production purposes zSecure Collect is normally run using job C2RJPREP. Copy this job to your batch job scheduling system, and customize it with your naming conventions and other local requirements. For details, see *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

Calling zSecure Collect using JCL

The call interface to CKFCOLL, the main zSecure Collect module, can follow the convention used for the JCL EXEC statement as well as the TSO command calling interface (CPPL). Note, however, that authorized execution from TSO requires an entry in the authorized command or authorized program list (IKJTSO*xx*). The following list describes the ddnames and file names that are supported.

SYSPRINT
Lists messages and statistics. The record format is set by default to `VBA` for non-`SYSOUT` files, and to `VA` for `SYSOUT` files. However, record formats `V`, `VB`, `F`, `FB`, `VA`, `FA`, `VBA`, and `FBA` are all supported. The record length defaults, depending on the record format, yield a printable line length 132. With the default `VBA` record format, this would yield 137 for the LRECL. A shorter line length (79 for example) is possible but results in truncation of some headers, messages, and report lines. If you do not specify a block size, a suitable default is chosen.

SYSTERM
Lists status messages and messages with a severity of 8 or higher. These messages are also printed on `SYSPRINT`. This file can be omitted.

CKFREEZE
All configuration information is written to a sequential file in VB or VBS format with a minimum `LRECL` of *23472*. The default is *VBS*.

The `LRECL` specified limits the length of VVDS and catalog records copied. If no `LRECL` is specified, then the `LRECL` value defaults to *X* which means that the record length is unlimited for VBS files and (`BLKSIZE - 4`) for VB files. You do not need to specify a value for `BLKSIZE` because the system can automatically determine the optimum block size for the device you are using.

ISPF shows the JCL specification `LRECL=X` as `LRECL=32768`. LRECL=X does *not* imply that records are 8 bytes longer than 32760. It implies support for multi-segmented records which are those records longer than 32K. Truncating these records to 32760 removes more than 8 bytes. For catalogs this processing behavior can explain the missing connector entries. If you have to process these data sets with utilities like file transfer, do not truncate `CKFREEZE` data sets after they have been created as part of the file transfer process. Instead, specify a smaller `LRECL` value like 32760 when you create or fill the data sets. zSecure Collect correctly folds records that exceed the `LRECL`. Do not terse a VBS `CKFREEZE` file.

The required space is approximately 2 megabytes per online DASD volume.

The CKFREEZE file can be a striped or compressed data set to increase postprocessing program throughput or to reduce space requirements.

Instead of allocating the `CKFREEZE` ddname in the JCL, an existing `CKFREEZE` data set name can also be allocated through the `CKFREEZE=dsn` parameter.

SYSIN
This file can contain parameters. They are described in the next section.

Sample JCL included is listed in “Getting Started” on page 1594.

zSecure Collect reports

zSecure Collect automatically generates reports on the collected information. To suppress reports, specify the NOREPORT option for zSecure Collect.

To view a report sample and list of field descriptions, see the following topics.

- "Volume overview report"
- "Partitioned data set overview" on page 1606
- "Catalog and VSAM CHECK overview" on page 1608
- "Migration, tape catalog, PDS/E, and non-VSAM CHECK overview" on page 1609
- "UNIX mount point overview" on page 1611
- "Summary report" on page 1612

Note: To limit the size of the samples, lines have been deleted from the reports.

Figure 534. zSecure Collect Volume Overview report

Table 639. zSecure Collect Volume overview Report - field descriptions

Column	Meaning
Storgrp	SMS Storage group or blank if none

Table 639. zSecure Collect Volume overview Report - field descriptions (continued)

Column	Meaning
Volume	Volume serial
Dev	Device address
VTOCtrk	Number of tracks allocated for VTOC
read	Number of VTOC tracks read
DSCB#	Number of DSCBs selected from VTOC
VSAM	Number of format 1 DSCBs with VSAM data set organization (components) including the counts for both format-8 DSCBs and format-1 DSCBs.
ISAM	Number of format 1 DSCBs with ISAM data set organization
nonVSAM	Number of non-ISAM, non-VSAM format 1 DSCBs
Ext	Number of format-3 DSCBs and format-9 DSCBs (indicates multiple extents)
VVDStrk	Number of tracks allocated to the VVDS
read	Number of VVDS tracks read
recs	Number of NVR and VVR records selected
CAT ix	Number of non-imbedded indices on the volume processed with EXCP
data	Number of ICF or HSM catalog data components on the volume processed with EXCP
slw	Number of ICF or HSM catalogs on the volume processed with VSAM GET
trks	Number of tracks read from the ICF or HSM catalog data components on the volume using EXCP
recs	Number of ICF and HSM catalog BCS records selected
PDS no	Number of partitioned data set directories on the volume processed with EXCP
trks	Number of tracks read from PDS directories on the volume
dirblk	Number of directory blocks read from partitioned data sets on the volume

In addition, the volumes can be flagged with up to three, one-letter flags. The legend for these flags is printed below the report if any of the flags was present. The following flags can appear:

Table 640. zSecure Collect Volume Overview Report - Volume flag indicators

Flag	Meaning
V.. Non-dedicated VM device	Virtual device under VM.
R.. Read-only	Read-only VM device.
T.. T-disk	VM temporary disk.
.S. Shared DASD	The volume has been generated as shared.
..N No VTOC on volume	Volume did not have VTOC at IPL time.
..C CP-formatted volume	Volume is in a format suitable for VM.
..A AIX-formatted volume	Volume is in a format suitable for AIX/ESA.

Table 640. zSecure Collect Volume Overview Report - Volume flag indicators (continued)

Flag	Meaning
..L Linux partition found	The VTOC contains at least one Format 1 DSCB for a Linux partition. This flag is only shown if the VTOC has been read.
..O Other OS (Amberjack)	The VTOC F4 DSCB indicates it is formatted for a non-z/OS Operating System (`Amberjack` volume). This flag is only shown if the VTOC has been read.
..U Unsupported VTOC	Volume Table of Contents format not recognized
..M VTOC moved	VTOC not on same track as during last mount.
..T I/O Timeout	I/O to the volume timed out, possibly in use by other system
..I Invalid or missing VTOC index	The volume has no valid VTOC index.

Table 641. zSecure Collect Partitioned data set overview report - field descriptions

Column	Meaning
Data set name	Name of the partitioned data set

Table 641. zSecure Collect Partitioned data set overview report - field descriptions (continued)

Column	Meaning
Dev	Device address of data set
Volume	Volume serial of data set
type	PDS for DSNTYPE=PDS or PDSE for DSNTYPE=LIBRARY
trks	Size of data set in tracks (1 for PDSEs, regardless of actual size)
read	Number of tracks read from directory and members using EXCP
members	Number of members read using EXCP (or BPAM, for PDSEs)
dirbl	Number directory blocks copied
A	The access that the user running the job has on the data set: None, Read, Update, Control, or Alter (blank without an AUDITRACF, AUDITACF2, or AUDITTSS focus).
flags	PDS attributes. The following attributes are reported: **Not found** Data set not found in VTOC. **Not mounted** Volume was not mounted or it was excluded. **APF** Data set is part of Authorized Program Facility list. **LPA** Data set is part of the link pack area list. **Lnk** Data set is part of LNKLST concatenation. **Proc** Data set is a JES2 procedure library. **Check** Checksum computation requested for all members. **Mismatch** Data set was not a PDS but requested as such.

Figure 535. zSecure Collect Catalog and VSAM CHECK overview report

Table 642. zSecure Collect Catalog and VSAM CHECK overview report - field descriptions

Column	Meaning
Data set name	Name of the catalog data component
Dev	Device address of data component
Volume	Volume serial of data component
IX blk	Index physical block size (bytes)
CISZ	Index control interval size (bytes)
ext	Number of extents for index
DA blk	Data component physical block size
CISZ	Data component control interval size (bytes)
CAtk	Number of tracks per control area for data component
ext	Number of extents for data component
trks	Number of tracks in use for data component (based on high used RBA)
read	Number of tracks read from data component using EXCP
records	Number of records selected from data component

Table 642. zSecure Collect Catalog and VSAM CHECK overview report - field descriptions (continued)

Column	Meaning
flags	Catalog attributes. The following attributes are reported: **Notfound** Volume not mounted. **Range** Key range data set (deprecated feature) **Repl** Sequence set replication (deprecated feature). **Imbed** Imbedded index (deprecated). **Nospan** Non-spanned data component. **Unconnected** No connector entry found in master catalog. **MCS** HSM Migration Control Data set. **BCD** HSM Backup Control Data set. **RMM** RMM Removable Media Manager control data set. **Mstr** Master catalog. **CHCK** VSAM data set requested on the CHECK statement. **+C** Catalog that has also been requested on the CHECK statement.

Figure 536. zSecure Collect Migration, tape catalog, PDS/E, and non-VSAM CHECK overview report

Table 643. Migration, tape catalog, PDS/E, and non-VSAM CHECK overview - field descriptions

Column	Meaning
Data set name	Name of the data set
Dev	Device address of data set
Volume	Volume serial of data set

Table 643. Migration, tape catalog, PDS/E, and non-VSAM CHECK overview - field descriptions (continued)

Column	Meaning
type	Type of data set. The following types are available: **ABR** FDR/ABR Archive control data set. **CHCK** Data set requested on the CHECK statement. **+C** Data set that has also been requested on the CHECK statement. **DMSF** DMSFILES data set. **DMSU** Unloaded DMSFILES data set. **PDSE** PDS/E directory. **PDSM** PDS member, DMS AUTHLIB. **TMC** CA1 Tape Management Catalog. **VMF** CA-TLMS Volume Master File.
Blksz	Physical block size from format 1 DSCB
Lrecl	Logical record length (LRECL) from format 1 DSCB
Trks	Number of tracks allocated for data set
used	Number of tracks in use for data set
read	Number of tracks read using `EXCP` (for PDSEs: number of directory blocks read using BSAM)
A	The access that the user running the job has on the data set. Any of the following values can be listed: *None*, *Read*, *Update*, *Control*, or *Alter* (blank without an AUDITRACF, AUDITACF2, or AUDITTSS focus).
Records	Number of records read
volumes	Number of volume records copied to `CKFREEZE` file
profiles	Number of RACF profile coding records copied to `CKFREEZE` file
datasets	Number of data set records copied to `CKFREEZE` file

```

Figure 537. zSecure Collect UNIX mount point overview report

Table 644. UNIX mount point overview - field descriptions

Column	Meaning
Data set name	Name of the UNIX File System data set that was mounted at the mount point.
Volume	Volume serial of data component. This column shows *client* when the file system is a UNIX File System of another system that is connected through XCF.
Directories	Number of UNIX directories read from the UNIX File System data set.
Failed	Number of directories that could not be read. This column shows `client=n` if the file system is a UNIX File System of another system that is connected through XCF, but collection was not requested (parameter UNIXCLIENT=N was specified) . The Directories and Files columns are blank in this case.
Files	Number of directory entries read from the directories.
with ACL	The number of files in the file system that have an access ACL. This column shows `unixacl=n` if the file system did contain any access ACLs, but collection was not requested.
Mount point	Absolute path name of the mount point for the UNIX File System data set

Summary report

```
CKFCOLL 1.9.0 06/05/07 13.19 HCKR181 I B M   T i v o l i   z S e c u r e   C o l l e c t                page   8
Summary

CKF008I 00 Number of DASD devices interrogated: 192
CKF009I 00 Number of DSCB entries copied: 42,535
CKF010I 00 Number of VVDS datasets processed: 162
CKF011I 00 Number of NVR/VVR entries copied: 13,396
CKF041I 00 Number of catalogs processed: 65
CKF042I 00 Number of BCS records copied: 83,910
CKF142I 00 Number of MCD records copied: 77,552
CKF143I 00 Number of BCD records copied: 42,662
CKF226I 00 Number of RMM control records copied: 4,013
CKF035I 00 Number of PDS directories processed: 163
CKF307I 00 Number of UNIX directory entries copied: 91,474 from 12,770 directories in 56 file systems
CKF338I 00 Number of UNIX ACL records copied: 53 access ACLs, 6 directory default ACLs, 4 file default ACLs
CKF560I 00 Number of CICS regions interrogated: 1, Transactions: 95, Programs: 263
CKF561I 00 Number of IMS regions interrogated: 3, Transactions: 67, PSBs: 133
CKF034I 00 CKFCOLL used 25.8 CPU seconds, 153 elapsed seconds, and collected 83.337 MB (0.545 MB/s)
           Written 390,665 records to C#MASCH.C2F160.CKFREEZE on SM3013
           Region requested 65,536KB, granted 11,176+65,536KB
           max used in jobstep 476+1,672KB
```

The summary report is always printed and gives an indication of the number of volumes and different kinds of records collected.

zSecure Collect command reference

The zSecure Collect program supports a number of parameters and commands that either restrict the information collected to a subset of your I/O subsystem, or that collect information for a specific purpose. Some restrictions are more limiting than others, and some restrictions can be combined to generate a subset. This section provides detailed information about each parameter and command including option descriptions, default settings, and any product-related restrictions. For example, some commands are available based on which products are installed and activated in your environment. For an overview of the commands supported by product feature, see Figure 532 on page 1596.

For details on the configuration and collection process, see "Getting Started" on page 1594 and "Configuring zSecure Collect" on page 1594.

Command syntax

You can specify the zSecure Collect parameters on the PARM field of the `EXEC` statement, or in the SYSIN file.

- Multiple parameters can be specified, separated by commas, semicolons, and/or blanks. The commands are not case-sensitive.
- If the `SYSIN` file is 80 characters wide, only positions 1 - 72 are read.
- Commands can be continued on the next line, but not in the middle of a word.
- The line end acts as a separator just like a blank or comma.
- If parameters are specified more than once, the value last given is used.
- Parameters on the `EXEC` statement or passed on a TSO command are processed before the parameters in the SYSIN file.
- All parameters are listed on the `SYSPRINT` file, prefixed with their origin (`PARM` or `SYSIN`).
- The *command order* is free, except that the `FOCUS` command must be specified before any command that is not permitted under each focus. Practically speaking, `FOCUS` should either be the first command or be omitted altogether.
- To indicate a comment, use `/*` at the beginning of the comment, and end the comment with `*/`.
- If not already part of such a comment, `*` also starts a comment, which then runs to the end of the line

Command parameters

zSecure Collect supports the following parameters.

ABR

Use this parameter to specify whether you want ABR archive records to be collected from the active Automatic Backup and Recovery (ABR) archive control file as defined in the LNKLST concatenation or STEPLIB module FDROPT.

ABR=NO
Specify *NO* to suppress collecting ABR archive records. This setting is implied by FOCUS=ALERT* and TCIM* if no other focuses are present.

ABR=YES
Specify *YES* to collect the ABR archive records. This value is implied by FOCUS=ADMINRACF, AUDIT*, and VISUAL, and is *only* valid under these focuses. If running under RACF with an AUDIT* focus but not APF authorized, the program only opens the archive control file automatically if the user has READ authority to it.

ALLOC

Use this parameter to manage the input and output for DASD devices.

ALLOC=NO
Specify *NO* if you only want to permit explicitly solicited I/O to DASD devices. If you use this setting, the following values are implied for the specified zSecure Collect parameters: DASD=N, PDS=N, MCD=N, BCD=N, CAT=N, TMC=N, DMS=N, RMM=N, VMF=N, UNIX=N, ABR=N. Consequently, you cannot set the values of these parameters to Y.

This setting does not prevent I/O to explicitly requested data set names. Neither does it prevent I/O to tape devices or ESCON switches which is what differentiates ALLOC=NO from UNITIO=NO. The CKFREEZE file includes all device numbers and volume names, but not the physical ids necessary to map (shared) DASD, nor the contents of any VTOC, VVDS, catalog, UNIX file system, or PDS.

ALLOC=YES
Specify *YES* (behind an IF command, for example) to negate the meaning of a previous ALLOC=NO statement.

ALLRECS

Use this parameter to request all ICF catalog, HSM MCDS and HSM BCDS, and RMM control records instead of a subset of record types used by zSecure products.

APF

Use this parameter to specify that APF authorization is considered essential. For example, you can specify the APF parameter when specific information is needed that requires the authorization granted by running APF. If authorization cannot be obtained, the program terminates with RC 12 and create a CKFREEZE file that only contains a zSecure Collect identification record. For a detailed discussion on authorization and when it is needed see "Deciding whether to run APF-authorized" on page 1601.

ARCDSN

The syntax for this command is:

ARCDSN= *dsn*
ARCDSN=dsn/vol

Use this parameter to request that the archive of the specified Automatic Backup and Recovery (ABR) archive control file be included in the CKFREEZE file. This parameter is only supported for FOCUS=ADMINRACF, AUDIT*, and VISUAL. Also see "Specifying alternate data sources" on page 1597.

AUTOMOUNT

Use this parameter to specify whether CKFCOLL causes an automatic mount for UNIX file systems that are not currently mounted.

AUTOMOUNT=NO
Specify *NO* if you do not want the UNIX files systems to be automatically mounted.

AUTOMOUNT=YES
Specify *YES* if you want UNIX file systems that are not currently mounted to be automatically mounted. This value is the default setting if UNIX=YES is specified or implied.

BCD

Use this parameter to specify whether to collect information from the active HSM Backup Control Data set.

BCD=NO
Specify *NO* if you do not want the HSM Backup Control Data set to be collected. This value is implied by FOCUS=ALERT* and TCIM* if no other focuses are present.

BCD=YES
Specify *YES* to request collection of the HSM Backup Control Data set information. This value is implied by FOCUS=ADMINRACF, AUDIT*, and VISUAL and permitted *only* under these focuses. It is *only* honored if the program is running APF-authorized, because APF authorization is needed to determine the data set name. Also, the HSM address space must be swapped in.

BURST parameters

Use the BURST parameters to manage the operation of I/O bursts.

BURSTS

The syntax for this parameter is BURSTS= *nn*.

Use this non-APF option to modify the number of I/O bursts done in an attempt to access a device along all its paths. The default value is 20.

BURSTWAIT

The syntax for this parameter is BURSTWAIT= *nn*.

Use this non-APF only option to modify the number of centiseconds waited between bursts. Specify a time period that gives a reasonable chance that an active I/O has terminated. The default value is 50.

BURSTSIZE

The syntax for this parameter is BURSTSIZE= *nn*.

Use this non-APF option to modify the number of I/Os in a burst done in an attempt to access a device along all its paths. It should at least be equal to the maximum number of paths to any device. The default value is 4.

CAPS

Use this parameter to request capitalization of output messages. This parameter does not affect the first page header or the parameter listing of previous parameters.

CAT

Use this parameter to manage the behavior of catalog data dumps. You can specify the following settings:

CAT=MCAT
Specify *MCAT* to cause the master catalog (but no user catalogs) to be dumped. All password fields in all records are overwritten with bytes containing hex EF to prevent security exposures. This parameter is only permitted if `CAT=Y` is permitted.

CAT=NO
Specify *NO* to suppress catalog dumps.

CAT=YES
Specify *YES* to cause the master catalog and all ICF user catalogs pointed to by the master catalog to be dumped. However, all password fields in all records are overwritten with bytes containing hex EF to prevent security exposures. It is the default when running APF authorized.

CHECK parameters

Use the CHECK parameters to determine whether you want checksum (*fingerprint*) computation to be done.

CHECK=DD

The syntax for this parameter is `CHECK=({DD|DDPREF}=` *`dd`*`)`.

Specify this value to request checksum, or fingerprint, computation for data sets. This is sometimes called *freezing*. All data sets allocated to the specified ddname, or matching the prefix on the `DDPREF`, are read and two checksum computations are performed: one for global comparison, and one for change control audit or virus detection. (The latter requires a user-specific CHECKPWD parameter.) The checksum for each data set in a concatenation is performed separately. For PDS and PDSE data sets selected with this method, checksum values are calculated on both the member and full data set level. VSAM key sequenced and relative record data sets, and concatenations with tape data sets, are not supported. This option is only supported for `FOCUS=AUDIT*`.

CHECK=DSN

The syntax for this parameter is `CHECK=({DSN|DSNPREF}=` *`dsn`*`[,DSORG=(PO|PS|VS)])`.

Use this parameter to request checksum (*fingerprint*) computation for data sets. This is sometimes called *freezing*. All data sets specified using the DSN or DSNPREF values are checked to see whether they have a matching DSORG (an omitted DSORG is equivalent to DSORG=(PO,PS,VS)). If so, they are read and two checksum computations are performed: one for global comparison, and one for change control audit or and virus detection. (The latter requires a user-specific CHECKPWD parameter.) For PDS(E) data sets selected with this method, checksums are calculated on both the member and full data set level. VSAM key sequenced and relative record data sets are not supported. The CHECK parameter is allowed under FOCUS=AUDIT*. Also see “Specifying alternate data sources” on page 1597.

CHECK=NO

Specify *NO* to deactivate checking (see CHECK=YES). This value is implied if zSecure Admin, Alert, Tivoli Compliance Insight Manager or Tivoli Security Information and Event Manager are active (FOCUS=ADMINRACF, ALERT*, TCIM*, and VISUAL, if no other focuses are present. The `CHECK=NO` setting is also the default for the AUDIT* focus.

CHECK=YES
Use this parameter to request checksum (*fingerprint*) computation at the member and data set level for partitioned data sets. This is sometimes called *freezing*. All partitioned data sets selected by the PDS, PDSDIR, and CHECKDSN parameters are read, and two checksum computations are performed: a *module level signature* for global comparison and another for change control audit or virus detection. The second computation is only performed when a value has been specified for the `CHECKPWD` parameter.

If `CHECK=YES` is specified, the `IDR` processing parameter for collecting load module identification for each member of a partitioned RECFM=U data set has no effect. In addition, scanning for the members is not activated unless SCAN=N is also specified. This is only supported for `FOCUS=AUDIT*`, but even then the default is CHECK=N.

CHECKDSN=
You can use any of the following syntax patterns for this command:

```
CHECKDSN= dsn
CHECKDSN=dsn/vol
```

Use this parameter if you want checksums to be computed at the member and data set level for the specified partitioned data set. Sequential data sets are *not* supported. This parameter can be combined with VTOC=N,PDS=N to make a `CKFREEZE` file that contains no data set information except the specified `CHECKDSN` data sets. Use the CHECK=Y parameter to request checksums for all APF libraries, LPA list data sets, LNKLST concatenation data sets, and JES2 and MSTR procedure libraries. It is *only* supported for FOCUS=AUDIT*. Also see "Specifying alternate data sources" on page 1597.

CHECKPWD=
You can use any of the following syntax patterns for this command:

```
CHECKPWD='txt'
CHECKPWD='txt'
CHECKPWD=word
```

The password has a length limit of 255. The `CHECKPWD=pwd` statement must fit in one line. If `CHECKPWD` is not specified, the site-specific identification string from the CKRSITE module is used.

To provide virus detection capabilities, specify the `CHECKPWD` parameter in combination with the `CHECK=Y` parameter. The password is used to influence the outcome of each member and data set *change detection* checksum (the actual means are non-disclosed).

The `CHECKPWD` parameter does not affect the *module level signature* checksum calculated for global comparison which is the same across multiple users and customers. Specifying different `CHECKPWD` parameters for different users prevents a virus from using the *module level signature* checksum value calculated when `CHECK=Y` for multiple users. To secure the `CHECKPWD` value so it is only accessible to authorized users, make sure that the invocation JCL is read-protected.

CICS

Use the CICS parameter to indicate whether CICS information is to be collected.

CICS=NO
Specify NO to suppress collection of all CICS transaction, program, library and security-related resource information.

CICS=YES
Specify YES to enable the collection of CICS transaction, program, library and security-related resource information.

Use of this option requires APF authorization and the use of cross-memory services. CICS data is not collected if the NOXMEM parameter is specified.

This option is implied by FOCUS=ADMINRACF, AUDIT*, ALERT*, and VISUAL. The option is supported for these focuses only. The following collection rules apply:

- If the FOCUS parameter values ADMINRACF, ALERT*, or VISUAL only are active, collection is restricted to security-related resource information.
- If at least one AUDIT* FOCUS parameter value is active, additional CICS information is collected.

CKFREEZE

You can use any of the following syntax specifications for this command:

```
CKFREEZE=['dsn'|'dsn(mem)'| dsn | dsn(mem)| pathname]
IOCONFIG=['dsn'| 'dsn(mem)'| dsn | dsn(mem) | pathname]
```

Use this parameter to indicate which data set name to allocate the `CKFREEZE` ddname or UNIX file to. The allocation is done with `DISP=SHR`. This specification replaces any current allocation to ddname `CKFREEZE`.

DASD

Use this parameter to manage the allocation behavior of the DASD devices in your system.

DASD=NO
Specify *NO* to prevent allocation of the DASD devices in your system except for reading special data sets. If no other parameters are specified, this setting results in collecting only the configuration information that can be found in the OS control blocks and that can be found by doing I/O to `TAPE` and `SWCH` devices. This includes all device numbers and volume names, but not the physical ids necessary to map (shared) DASD, nor the contents of any VTOC, VVDS, catalog, or PDS. The difference with `ALLOC=N` is that data set contents can still be requested or implied through additional parameters such as `PDS=Y`.

DASD=YES
Specify *YES* (behind an IF command, for example) to negate the meaning of a previous `DASD=NO` statement.

DB2

Use the DB2 parameter to indicate whether DB2 information is to be collected.

DB2=NO
Specify NO to suppress the collection of DB2 region and security-related resource information.

DB2=YES
Specify YES to enable the collection of DB2 region and security-related resource information.

Use of this option requires APF authorization. Some DB2 data is not collected if the NOXMEM parameter is specified.

DEBUG parameters

Use these parameters to manage debugging behavior.

DEBUG

Use this parameter to print debugging information. The INFO parameter must also be specified. Use this parameter only at the request of IBM software support.

DEBUGHANGTEST

The syntax for this parameter is DEBUGHANGTEST= *n*

Use this parameter to specify the program location for the DEBUGHANGVOLUME test. Currently defined locations are 1 (VTOC sense), 2 (VTOC index), 3 (VTOC data), 4 (VSAM by EXCP), 5 (VSAM by VSAM), 6 (between SVC99 and VTOC OPEN). The default is 1. Use this parameter only at the request of IBM software support.

DEBUGHANGVOLUME

The syntax for this command is DEBUGHANGVOLUME= *volume*.

This value identifies on which volume to issue a long wait. In combination with the HWRESERVE parameter, this option causes other systems that need this volume to issue START PENDING messages. Use this parameter to help debug a problem only at the request of IBM software support.

DMS

Use the DMS parameters to determine whether information from the active DMSFILES and AUTHLIB data sets is collected and to specify specific files for collection.

DMS=NO

Specify *NO* to suppress the data collection. This value is implied by FOCUS=ALERT* and TCIM* if no other focuses are present.

DMS=YES

Specify *YES* to request collection of the DSNINDEX and RACFENCD information in the DMSFILES data set of the active DMS as defined in the LNKLST concatenation or STEPLIB. In addition, if DMS PARMLIB security is active, the list of authorized parameter libraries is read from the authorized library (AUTHLIB) member defined by the active DMS. This option is implied by FOCUS=ADMINRACF, AUDIT*, and VISUAL. The option is *only* supported for these focuses. If running under RACF with an AUDIT* focus but without APF authorization, the program only opens the DMSFILES data set automatically if the user has READ authority to it.

DMSFILES=

You can use either of the following syntax patterns to specify this parameter.

```
DMSFILES= dsn
 DMSFILES=dsn/vol
```

Specify this parameter to include the contents of the specified DMSFILES data set in the CKFREEZE file. It is *only* supported for FOCUS=ADMINRACF, AUDIT*, and VISUAL. Also see “Specifying alternate data sources” on page 1597.

DMSPARMS=

You can use either of the following syntax patterns to specify this parameter.

```
DMSPARMS=dsn
 DMSPARMS=dsn/vol
```

Specify this parameter to include the contents of the specified DMSPARMS data set member SYSPARMS in the CKFREEZE file. It is *only* supported for FOCUS=ADMINRACF, AUDIT*, and VISUAL. Also see "Specifying alternate data sources" on page 1597.

DMSUNL=

You can use either of the following syntax patterns to specify this parameter.

```
DMSUNL= dsn
 DMSUNL=dsn/vol
```

Specify this parameter to include the contents of the specified DMSFILES unload in the CKFREEZE file. It is *only* supported for FOCUS=ADMINRACF, AUDIT*, and VISUAL. Also see "Specifying alternate data sources" on page 1597.

ENQ

Use this parameter if you want CKFCOLL to request collection of information from data sets that are exclusively allocated to another user. There is no guarantee that the collection process is completed. To use this parameter, specify ENQ=NO.

ERRDD

Use this parameter to redirect the SYSTERM output to a user-specified *ddname*. This parameter can only be used as a calling parameter in the PARM keyword in JCL. It cannot be used as a command in the input file.

You can use the following syntax to specify this parameter.

```
ERRDD=ddname
```

EXCLUDE

You can use either of the following syntax patterns for this command.

```
EXCL= list
 EXCLUDE= list
```

The EXCLUDE command. See "Selecting data by device or volume" on page 1599.

EXIT

You can specify this command using any of the following syntax patterns:

```
EXIT
 EXIT=([RC=rc],[NOCLEAR|CLEAR])
```

Use the EXIT keyword to stop zSecure Collect after only reading its input. No processing other than syntax verification is done. *rc* is the return code with which zSecure Collect ends. This can be any number in the range 0...99. It is 12 by default. The NOCLEAR value can be specified to indicate that the CKFREEZE file that would have been written by this zSecure Collect run should be left intact so that other processes that depend on its presence do not fail. The default value, CLEAR, indicates that CKFREEZE file is cleared so that it only contains the messages written by the syntax verification process. Using the CLEAR option ensure that no reports are generated with an outdated CKFREEZE file as input. The RC and (NO)CLEAR values are not inherited from previous EXIT statements. When multiple EXIT statements are encountered, the last statement is used with the RC and (NO)CLEAR values that are specified on that statement. If RC and (NO)CLEAR are not specified in the statement, the default values are used.

FOCUS

Use any of the following syntax patterns to specify this command:

```
FOCUS= focus
F=focus
 FOCUS=list
  F=list
```

Use this parameter to specify the intended use of the configuration data. You can specify any of the following values: ADMINRACF, AUDITACF2, AUDITRACF, AUDITTSS, VISUAL, ALERTACF2, ALERTRACF, TCIMACF2, TCIMCICS, TCIMDB2, TCIMRACF, or TCIMTSS. This parameter automatically sets the proper combination of data collection options for the IBM Security zSecure Admin, zSecure Audit for ACF2 (for ACF2, RACF, or Top Secret), zSecure Visual, zSecure Alert (for ACF2 or RACF), and Tivoli Compliance Insight Manager Enabler for z/OS for z/OS (for ACF2, CICS, DB2, RACF, or Top Secret) products, respectively.

Instead of one focus, a list of focuses can be specified enclosed in parentheses. Alternately, you can specify the value ALL or LICENSED to request all focuses recognized by zSecure Collect, which is equivalent to omitting the FOCUS keyword. Also see "Selecting the products for the collect operation" on page 1595.

FREE

Use this parameter to free the files used dynamically as soon as processing has finished. Setting this option makes processing much slower than it is if the default setting is used where all files that are used are freed at one time remain allocated until step termination. If this parameter is not specified, the program starts freeing individual files when it estimates there is space in the TIOT for less than 10 additional ddnames. See message CKF297I at the end of the SYSPRINT for information about actual numbers being freed.

FREEZEDD

Use the FREEZEDD statement to specify the ddname to be used for the CKFREEZE data set.

Use the following syntax to specify this command:

```
FREEZEDD=ddname
```

The specified ddname is used to replace the default CKFREEZE value. The ddname is also used to allocate the data set that have specified on the CKFREEZE statement, if it has not been allocated.

HFS parameters

The following HFS parameters are equivalent to the corresponding UNIX parameters. For details, see "UNIX parameters" on page 1633.

Table 645. HFS parameters

HFS parameter	Equivalent Unix parameter
HFS=YES	UNIX=YES
HSF=NO	UNIX=NO
HFSCLIENT=YES	UNIXCLIENT=YES
HSFCLIENT=NO	UNIXCLIENT=NO

HSM parameters

Use the HSM parameters to control collection of HSM Backup and Migration data.

HSMBCD=

Use either of the following syntax patterns for this command:

```
HSMBCD= dsn
  HSMBCDS=dsn/vol
```

Use this parameter to include the contents of the specified HSM Backup Control data set in the CKFREEZE file. This option is *only* supported for FOCUS=ADMINRACF, AUDIT*, and VISUAL. Also see "Specifying alternate data sources" on page 1597.

HSMMCD=

Use either of the following syntax patterns for this command:

```
HSMMCD= dsn
 HSMMCDS=dsn/vol
```

Use this parameter to include the contents of the specified HSM Migration Control data set in the CKFREEZE file. This option is *only* supported for FOCUS=ADMINRACF, , AUDIT*, and VISUAL. Also see "Specifying alternate data sources" on page 1597.

HWRESERVES (no longer valid)

This parameter is no longer valid.

ICFCAT

Use either of the following syntax patterns for this command:

```
ICFCAT= dsn
ICFCAT=dsn/vol
```

Use this parameter to request that the catalog contents of the specified ICF catalog be included in the CKFREEZE file. Also, see "Specifying alternate data sources" on page 1597.

IDR

Use this parameter to control the collection of load module identification for each member of a partitioned RECFM=U data set.

IDR=NO

Specify *NO* (behind an IF command, for example) to negate the meaning of a previous IDR=YES statement or default. NO is the default, unless CHECK=YES is also specified. If that option setting is specified IDR=YES is the default value.

IDR=YES

Specify *YES* to request extraction of the load module identification information If you specify this setting, all partitioned data sets selected by the PDS, PDSDIR, and CHECKDSN parameters are read. The information consists of link-edit date, any ZAP information, and unique IDR strings (usually PTF numbers) with the most recent date that accompanies each string. The IDR=YES setting is supported *only* for FOCUS=AUDIT*, but even then the default is IDR=N. IDR=Y is implied by CHECK=Y.

IF

Use any of the following syntax patterns for this command.

```
IF symbol = list :
IF symbol <> list
```

Use this keyword to skip or include a line of parameters, based on the SMFID of the system or a Static System Symbol. You can specify the following variables with this keyword.

symbol
Specify any symbol in the Static System Symbol table without the preceding ampersand or ending period or the SMFID. If the symbol cannot be found in the Static System Symbol table, this field is considered empty and only matches an empty string.

list
Either a single value or a list of comma-separated values, enclosed in parentheses. Each value can be enclosed in double or single quotation marks. Values specified without quotation marks are converted to uppercase. If a value is an empty string or contains lowercase characters, non-alphanumeric characters, or national characters, you must enclose the value in quotation marks. Trailing blanks in either the symbol or the value are ignored.

When the test specified in the IF statement evaluates to false, the rest of the line is skipped which means that no syntax checking occurs. If the test evaluates to true, the rest of the line is parsed normally. Do not put the IF statement itself at the start of a line. IF statements can be nested, but no end-of-line is permitted between the IF and the colon (:) marking the end of the test condition. A blank is required after the colon.

IMS

Use the IMS parameter to indicate whether IMS information is to be collected.

IMS=NO
Specify NO to suppress the collection of IMS transaction, PSB and security-related resource information.

IMS=YES
Specify YES to enable the collection of IMS transaction, PSB and security-related resource information.

Use of this option requires APF authorization. Some IMS data is not collected if the NOXMEM parameter is specified.

This option is implied by FOCUS=ADMINRACF, AUDIT*, ALERT*, and VISUAL. The option is supported for these focuses only. The following collection rules apply:

- If the FOCUS parameter values ADMINRACF, ALERT*, or VISUAL only are active, collection is restricted to security-related resource information.
- If at least one AUDIT* FOCUS parameter value is active, additional IMS information is collected.

INDD

Use this parameter to redirect SYSIN to a user-specified data set *ddname* so that SYSIN is read from the specified ddname. This parameter can only be used as a calling parameter in the PARM keyword in JCL. It cannot be used as a command in the input file.

You can use the following syntax to specify this parameter.

```
INDD=ddname
```

INFO

Use this parameter to obtain information about the progress of processing. The information is not presented in a structured way, but it can be used to get an insight in the amount of parallelism. The INFO parameter is mainly intended for debugging and analyzing zSecure Collect performance.

INTERVAL (no longer valid)

This parameter is no longer valid.

IO parameters

Use the IO command to specify whether solicited I/O to devices is permitted and to specify a timeout value.

IO=NO

Specify *NO* to prevent any solicited I/O to devices. This setting implies ALLOC=N, DASD=N, PDS=N, MCD=N, BCD=N, CAT=N, TMC=N, DMS=N, RMM=N, VMF=N,UNIX=N, ABR=N, TAPE=N, SWCH=N. (That is, these parameters cannot be set to Y.) If no other parameters are specified, it results in collecting only the configuration information that can be found in the OS control blocks. This includes all device numbers and volume names, but not the physical ids necessary to map (shared) DASD tapes, and switches, nor the contents of any VTOC, VVDS, catalog, UNIX file system, or PDS. Explicitly requesting special data sets by data set name does *not* result in I/O (this is the difference with UNITIO=N).

IO=YES

Specify YES to negate the meaning of a previous IO=NO statement, behind an IF command for example.

IOTIMEOUT

The syntax for this parameter is IOTIMEOUT= *nnn*.

Use this parameter to change the default timeout period for the Missing Interrupt Handler, or to deactivate it. The default value is *60* seconds. To deactivate the timeout mechanism, set this value to *0*. When the mechanism is deactivated, the Missing Interrupt Handler shows START PENDING messages on the console if it misses an interrupt. The IOTIMEOUT parameter prevents the program from hanging on a long reserve if the program runs with APF authorization and SIO=YES. This setting does not necessarily prevent hanging if the long reserve starts while the program is already doing I/O to the device. The I/O timeout feature only works on z/OS release 1.2 and higher.

LICENSE (no longer used)

This parameter is no longer used.

MCD

Use this parameter to determine whether information is collected from the active HSM Migration Control Data set.

MCD=NO

Specify *NO* if you do not want to collect information from the active HSM Migration Control Data set. This setting is implied by FOCUS=ALERT*, and TCIM* if no other focuses are present.

MCD=YES

Specify *YES* to request collection of the information from the Migration Control Data set of the active HSM. This setting is implied by FOCUS=ADMINRACF, AUDIT*, and VISUAL and is *only* supported for these focuses. This setting is only honored if the program is running APF-authorized, because APF authorization is needed to determine the data set name. Also, the HSM address space must be swapped in to do this automatically.

MOD

Use this parameter to control the collection of load module and exit information. This includes SVC and PC routines. RACF and ACF2 exit information will always be collected regardless of the setting.

MOD=NO
Specify NO to not collect module information.

MOD=YES (default)
Specify YES to collect all load modules, SVC and PC routines, and exit information.

MONITOR (no longer valid)

This parameter is no longer valid.

NJE

Use this parameter to control the collection of JES node information.

NJE=NO
Specify NO to not collect JES node information.

NJE=YES (default)
Specify YES to collect JES node information.

NOBSAMBPAM

This parameter is valid on the `PARM` string only. Use this setting to disable use of the BSAM and BPAM access methods by the program. The program uses QSAM instead. Use this parameter only at the request of IBM software support.

NOBYPASS

Use this APF-only parameter to prevent bypassing data set security for dumping ICF and HSM catalogs, PDS directories, and DMS, ABR, CA1, TLMS, and RMM data sets. Use this parameter only at the request of IBM software support.

NOCLOSE

Use this parameter to leave files open at abnormal termination of the program to be able to debug problems. It can only be used in the parameter string, not in the SYSIN file. Use this parameter only at the request of IBM software support.

NODCBE

Use this parameter if you do not want to use buffers above 16 MB for certain input files. This option can only be used in the parameter string, not in the SYSIN file. Use this parameter at the request of IBM software support.

NODIAG

Use this APF-only option to prevent use of the `DIAGNOSE` instruction to issue VM queries if MVS is running under VM. This option causes VM-specific data to be missing. It can also cause command rejects on 3990 devices (message IOS000I) because VM blocks certain query CCWs. Use this parameter only at the request of IBM software support.

NOKEY0

Use this APF-only option to prevent use of the APF-authorized access to fetch protected control blocks (like the PPT and TCAST). This causes the fetch protected information to be missing. Use this parameter only at the request of IBM software support.

NOMSG

The syntax for this parameter is `NOMSG= list`

This option is equivalent to the SUPMSG. See "SUPPRESS" on page 1631.

NOREPORT

Use this option to suppress the volume, PDS, special data set, and catalog reports.

NOSIO

This APF-only option can be set to prevent use of the APF-authorized I/O driver. This causes fallback to non-authorized ways of finding paths for DASD devices. No path information is found for tape devices. No cache size and caching status information is collected for 3880 model 23 devices. Use this parameter only at the request of IBM software support.

NOUID0

This APF-only option can be used to prevent the use of APF authorization to switch to UNIX UID 0 in order to scan all file system directories. If this option is specified, file system access is done under the UID for the user, which might cause a failure to read some directories. Use this parameter only at the request of IBM software support.

NOXMDSN

This APF-only option can be set to prevent collecting data set names and types by means of cross memory instructions (a subset of cross memory operation). Use this parameter only at the request of IBM software support.

NOXMEM

This APF-only option can be set to prevent the use of any cross-memory instructions. It results in missing information about PC/AUTH, RMF, HSM, RMM, and JES2. Use this parameter only at the request of IBM software support.

OFFLINE

The syntax for this parameter is `OFFLINE=YES`.

Use this parameter to include UCB type information for offline devices.

OUTDD

Use this parameter to redirect the `SYSPRINT` output to a user-specified *ddname*. This parameter can only be used as a calling parameter in the PARM keyword in JCL. It cannot be used as a command in the input file.

You can use the following syntax to specify this parameter.

```
OUTDD=ddname
```

PARALLEL

Use either of the following syntax patterns for this command:

```
PARALLEL= option
 PAR=option
```

Use this parameter to select the amount of parallelism, and hence the amount of storage used by zSecure Collect. When you specify `PARALLEL`, the *option* variable can have any of the following values.

Table 646. CKFCOLL PARALLEL parameter - available option values

Option	Description
NONE	Forces sequential operation, that is to access only one device at a time.
PATHGROUP	Requests a maximum of one I/O per group of paths (and hence per LCU). Use this value if there is insufficient storage available for the default, or if PATH adds too much I/O to a heavily loaded LCU.
PATH	PATH is the default setting. This setting indicates that I/O is scheduled for at most one device per channel path.

PATH

Use this parameter to determine processing behavior for all paths to a device.

PATH=YES

Specify *YES* to include processing to obtain information across all paths to a device.

PATH=NO

Specify *NO* to suppress processing to obtain information across all paths to a device. This value is the default setting.

PDS

Use the PDS parameters to control the behavior of PDS directory dumps and determine the type of data to be included in the dumps.

PDS=

Use the PDS parameter to determine whether the PDS directory is dumped.

PDS=NO

Specify *NO* to suppress PDS directory dumps. This setting is the default if the program is not running APF-authorized. This value was chosen as the default to prevent a large number of 913-38 abends.

PDS=YES

Specify *YES* to cause collection of PDS and PDS/E directories of APF, LNKLST concatenation, and LPA list data sets as well as JES2 and MSTR procedure libraries, IEFJOBS, and SYS1.UADS (the latter only with FOCUS=AUDIT*). This setting is implied if the program is running under RACF or running APF-authorized. Keep the following processing considerations in mind when using this parameter with the CKFCOLL program.

- If the program is not running APF-authorized or under RACF with an AUDIT* focus, the PDS=YES parameter must be specified explicitly.
- If the program is not running APF-authorized or under RACF with an AUDIT* focus, READ access is required to all PDSs to be accessed.
- If the program is not running APF-authorized but is under RACF with an AUDIT* focus, the program only accesses partitioned data sets automatically if the user has READ authority to.

PDSDIR=

Use either of the following syntax patterns for this command.

```
PDSDIR= dsn
 PDSDIR=dsn/vol
```

Use this parameter to specify that the directory information of the indicated partitioned data set is included in the CKFREEZE file. This option is only permitted for FOCUS=ADMINRACF, ALERT*, AUDIT*, and TCIM*. Also see "Specifying alternate data sources" on page 1597.

PDSEBUFSIZE

The syntax for this command is PDSEBUFSIZE= *nn*.

Use this parameter to set an upper limit to the amount of user IDR data to store per PDSE program object, in kilobytes This parameter is only relevant if IDR=YES has been specified or implied. The *nn* value can be in the range of 1 to 1024, inclusive, and defaults to 128. Because the program typically uses about 10 of these buffers per PDSE, specifying a lower value can significantly reduce storage use.

RECALL

Use this parameter to determine whether the CKFCOLL program tries to recall (HSM) or restore (DMS or ABR) the data sets containing requested information (PDS directories, for example) if they are not found on their volume.

RECALL=NO

Specify *NO* to warn zSecure Collect not to attempt to recall (HSM) or restore (DMS or ABR) the data sets not found on their volume. This setting is the default for FOCUS=VISUAL only. RECALL is a synonym of RESTORE. If RECALL=NO is combined with VTOC=NO, alternate data sources for which no volser is explicitly specified might not be processed. For details, see "Specifying alternate data sources" on page 1597.

RECALL=YES

Specify *YES* (behind an IF command, for example) to negate the meaning of a previous RECALL=NO statement or default. YES is the default value if FOCUS=ADMINRACF, ALERT*, AUDIT*, or TCIM*.

REPORT

Use this parameter to create volume, catalog, and special data set reports. This option is set by default.

RESTORE

Use this parameter to determine whether the CKFCOLL program tries to recall (HSM) or restore (DMS or ABR) the data sets containing requested information (PDS directories, for example) if they are not found on their volume. This parameter is a synonym for the RECALL parameter.

RESTORE=NO

Specify *NO* to warn zSecure Collect not to attempt to recall (HSM) or restore (DMS or ABR) the data sets not found on their volume. This setting is the default for FOCUS=VISUAL only. RECALL is a synonym of RESTORE. If RESTORE=NO is combined with VTOC=NO, alternate data sources for which no volser is explicitly specified might not be processed. For details, see "Specifying alternate data sources" on page 1597.

RESTORE=YES

Specify *YES* (behind an IF command, for example) to negate the meaning of a previous RESTORE=NO statement or default. YES is the default value if FOCUS=ADMINRACF, ALERT*, AUDIT*, or TCIM*.

RMM

Use this parameter to control whether CKFCOLL collects information from the active RMM control data set. It is implied by FOCUS=ALERT*, TCIM*, and VISUAL if no other focuses are present.

RMM=NO
Specify *NO* to suppress collection of information from the active RMM control data set. this setting is implied by FOCUS=ALERT*, TCIM*, and VISUAL if no other focuses are present.

RMM=YES
Specify *YES* to cause collection of RMM volume, data set, and ownership records from the Removable Media Manager (RMM) control data set of the active RMM system as defined by storage control blocks. This option is implied by FOCUS=ADMINRACF and AUDIT*, and is *only* supported for these focuses.

RMMCTL

This command can be specified using either of the following statements:

RMMCTL= *dsn*
RMMCTL=*dsn/vol*

command is PDSEBUFSIZE= *nn*.

Request to include the tape data set, volume, and owner data from the specified Removable Media Manager Control data set in the CKFREEZE file. It is *only* supported for FOCUS=ADMINRACF and AUDIT*. Also see "Specifying alternate data sources" on page 1597.

SCAN

Use this parameter to control scanning operation of in-core modules and PDS members selected for checking using the CHECK and CHECKDSN parameters.

SCAN=NO
Specify *NO* to deactivate scanning. This value is implied if no AUDIT* focuses are present.

SCAN=YES
Specify YES to activate scanning of in-core modules selected for eye catcher processing, as well as PDS members selected for checking (by means of the CHECK and CHECKDSN parameters). Scanning is performed for dangerous functions that warrant auditing of the module and for the strings implied by the SCANSVC and SCANSTR parameters. This value is implied by FOCUS=AUDIT*, and is *only* supported under these focuses.

SCANSTR= *list*
Use this parameter to specify a text string, or a list of text strings enclosed in parentheses and separated by commas to be used for scanning. In-core modules like SVCs and exits, as well as PDS members are scanned for the text strings (PDS members only if CHECK=Y or CHECKDSN= has been specified). Only the first 7 strings in the list are reported separately per member in the CKFREEZE file. Hits in the remaining set of strings are combined into one yes/no flag. A text string can be a word (without quotation marks, blanks, or separators), a string enclosed in single quotation marks (without single quotation marks in the string), or a string enclosed in double quotation marks (without double quotation marks in the string). The length is limited to 255 bytes and each text string in the list must fit in one line. For FOCUS=AUDIT*, a scan argument is automatically added to search for a specific published security exposure in a third-party product.

SCANSVC= *list*
Use this parameter to specify either one SVC number in decimal or a list of SVC numbers (decimal) enclosed in parentheses and separated by commas to be used for scanning. In-core modules like SVCs and exits, as well as PDS members on DASD are scanned for SVC instructions invoking the specified SVCs. PDS members are scanned only if CHECK=Y or CHECKDSN= has been specified. Only the first 7 numbers in the list are reported separately per member in the CKFREEZE file; hits in the remaining set of SVCs calls are combined into one yes/no flag.

SELECT

You can specify this command using any of the following statements:

```
SELECT= list
SEL= list
S=list
```

syntax for this command is `S = list.`

The SELECT command. See "Selecting data by device or volume" on page 1599.

SERIALIZATION

The syntax for this command is `SERIALIZATION=( serialization-options).`

Use this option to specify which measures the program takes to ensure data integrity for the CKFREEZE data set. For serialization to operate properly, all jobs involved need to use the same resource name. That is, all jobs must specify the same ENQ option. All jobs should furthermore access data sets under their true names. Do not use aliases because a successfully acquired alias does not guarantee that the data set is available under its true name. The serialization options that can be specified are:

ENQ=(*qnames***)**
Serialization option for ensuring data integrity and input data availability by specifying that the program issue the appropriate ENQ request. You can specify the following subparameters to indicate the desired type of processing:

CKRDSN
The program issues a sysplex-wide exclusive ENQ with the specified QNAME for the CKFREEZE data set that it writes to. This way, it is guaranteed that no other process attempts to read the CKFREEZE while the system refreshes it.

SYSDSN
The program issues a system-wide shared ENQ with this QNAME for the CKFREEZE data set it writes to. This ENQ is intended to be used in combination with the WAIT serialization option, so that the program can wait until the required data set is available. Alternatively, when used in combination with the FAIL serialization option, an error message is issued if the data set is not immediately available, and further processing is ended. Issuing an ENQ request for QNAME SYSDSN requires that the program be APF authorized.

This option is mutually exclusive with NOENQ.

FAIL
This serialization option specifies that the program is to abort further processing if the CKFREEZE data set for which an ENQ is requested is not immediately available. This option is mutually exclusive with WAIT. If neither is specified, FAIL is the default.

MAXWAIT(*nn*)
This serialization option specifies the maximum time the program should wait for the CKFREEZE data set for which an ENQ is requested to become available, in minutes. Supported values are 1 - 59, inclusive, with a default value of 5 minutes. This option only has an effect in conjunction with serialization option WAIT.

NOENQ
This serialization option specifies that no ENQs are to be issued. This option is mutually exclusive with ENQ.

UNIT
This serialization option specifies that, if need be, dynamic allocation waits until a unit becomes available to satisfy the allocation request. It applies mostly to tape data sets. This option requires that the program be APF authorized.

VOLSER
This serialization option specifies that, if need be, dynamic allocation waits until the required volser becomes available. It applies mostly to tape data sets. This option requires that the program be APF authorized.

WAIT
This serialization option specifies that the program is to wait until the CKFREEZE data set for which an ENQ is requested is available. This option is mutually exclusive with FAIL. If the program is APF authorized, you can use the MAXWAIT serialization option to specify a maximum wait time. An unauthorized program can only wait until the CKFREEZE data set is available.

By default, the program uses the settings SERIALIZATION(ENQ(CKRDSN),FAIL. Any errors encountered during input parsing cause the program to revert to these default settings.

SHARED

Determines how information from shared disk devices is processed.

SHARED=NO

Specify NO to turn off processing for information from shared disk devices, unless system-specific. When this option is selected, no records are written for VTOC, VVDS, user catalog, migration, backup, or tape catalog information for volumes generated as *shared*. Although records are not written, the VTOC and VVDS are still read–not dumped–to scan for data sets of importance. In addition, the PDS directories selected or implied are all dumped, as is the master catalog.

Use this parameter when you want to reduce processing time in (partially) shared DASD configurations. This can be accomplished by running zSecure Collect without specifying SHARED=NO on one system and specifying SHARED=NO on the other systems. ***Note***: If the zSecure Collect FOCUS parameter specifies ADMINRACF, AUDIT*, and TCIM*, setting SHARED=NO might result in missing migration catalog or user catalog information if these catalogs are different among the systems that are sharing the volumes, and the catalogs do not reside on a non-shared volume.

SHARED=YES

Specify SHARED=YES to negate the effect of a previousSHARED=NO statement. For example, if you have specified SHARED=NO but want to enable information processing of information from shared volumes under some conditions, you can specify SHARED=YES within an IF statement. *YES* is the default value for the SHARED keyword.

SIGVER

This parameter determines whether signature verification information is to be collected when collecting directory information from a PDSE (partitioned data set extended).

SIGVER=NO
When SIGVER=NO is specified zSecure Collect does not collect signature verification information. This is the default value for this parameter.

SIGVER=YES
When the signature verification service is available on a z/OS system, use the SIGVER=YES parameter setting to enable the collection of signature verification information when collecting directory information from a PDSE (partitioned data set extended). If the signature verification service is not available message CKF362I is issued and the job terminated.

Signature verification is not done if the following zSecure Collect parameter values are specified: DASD=N or PDS=N.

SLOWDOWN

Use this option to force the use of VSAM OPEN and GET commands to read all catalogs. Its main use is to maintain operation in a pre-DFP V3 system without APF authorization, but with ALTER permits on the catalogs.

SMS=NO

Use this parameter to suppress SMS calls to obtain information about all structures except storage groups. This can save some elapsed time if you do not need SMS construct data. The default is to read SMS construct data for all focuses.

STATS (no longer valid)

This parameter is no longer used.

STORAGEGC

Use this parameter to turn on garbage collection during the run. In some cases this reduces storage consumption, but CPU usage increases. It can only be used in the parameter string, not in the SYSIN file.

SUPPRESS

This command can be specified using any of the following syntax:

```
SUPMSG=list
SUPP=list
SUPPMSG=list
  SUPPRESS=list
```

Use this command to suppress all messages with the specified number or numbers. You can specify one decimal number, or a list of numbers enclosed in parentheses and separated by commas. For instance, SUP=17 suppresses 'path not operational' messages that are to be expected in an LPAR system.

SWCH (no longer valid)

This parameter is no longer valid.

TAPE (no longer valid)

The TAPE parameter is no longer used.

TCPIP

Use this parameter to control the collection of TCP/IP stack configuration data and CS Resolver configuration data. In order to collect this data, CKFCOLL must run APF-authorized.

TCPIP=NO
Specify *NO* to turn off collection of TCP/IP stack configuration data and CS Resolver configuration data from the Communications Server.

TCPIP=YES
Specify *YES* to enable the collection of TCP/IP stack configuration data and CS Resolver configuration data. The value `TCPIP=YES` is authorized with an entitlement for the following products: `AUDITACF2`, `AUDITRACF`, `AUDITTSS`, `ALERTACF2`, or `ALERTRACF`. TCPIP=YES is the default value for systems with the correct entitlement.

TMC

Use this parameter to determine whether active CA1 Tape Management Catalog is collected.

TMC=NO
Specify *NO* to suppress data collection from the active CA1 Tape Management Catalog. This value is implied by `FOCUS=ALERT*`, `TCIM*`, and `VISUAL` if no other focuses are present.

TMC=YES
Specify *YES* to cause collection of TMC volume records and DSNB records from the Tape Management Catalog (TMC) of the active CA1 as defined by an MVS subsystem. This option is implied by `FOCUS=ADMINRACF` and `AUDIT*`, and is *only* supported by these products. If running under RACF with an `AUDIT*` focus but not APF authorized, the program only opens the tape catalog automatically if the user has READ authority to it.

TMCDSN

This command can be specified using any of the following syntax:
`TMCDSN= dsn`
`TMCDSN=dsn/vol`

Request to include the tape catalog contents of the specified UCC1 or CA1 Tape Management Catalog in the `CKFREEZE` file. It is *only* supported for the entitlements `FOCUS=ADMINRACF` and `AUDIT*`. Also see "Specifying alternate data sources" on page 1597.

UNCONNECTED

Use this APF-only option to set unconnected catalogs for dumping. The main use for this option is during volume selections that exclude the master catalog volume. `OPEN` for unconnected catalogs requires either APF authorization or inclusion of a `STEPCAT` or `JOBCAT` ddname for the unconnected catalog.

UNITIO

Use this parameter to control behavior of I/O to devices.

UNITIO=NO
Specify *NO* to only authorize explicitly solicited I/O to devices. This setting implies the following CKFCOLL parameter settings: `ALLOC=N`, `DASD=N`, `PDS=N`, `MCD=N`, `BCD=N`, `CAT=N`, `TMC=N`, `DMS=N`, `RMM=N`, `VMF=N`, `UNIX=N`, `ABR=N`, `TAPE=N`, and `SWCH=N`. (That is, these parameters cannot be set to `Y` unless `UNITIO` itself is overridden). This does not prevent I/O to explicitly requested data set names. The `CKFREEZE` file includes all device numbers and volume names, but not the

physical ids necessary to map (shared) DASD tapes, and switches, nor the contents of any VTOC, VVDS, catalog, UNIX file system, PDS, or tape/DASD management catalog unless requested by data set name.

UNITIO=YES
Specify *YES* (behind an IF command, for example) to negate the meaning of a previous `UNITIO=NO` statement.

UNIX parameters

Use these parameters to whether UNIX file directory data is collected and to specify the type of data collected.

UNIX =

UNIX=NO
Specify *NO* to suppress collection of z/OS UNIX file directory data. This setting is implied by `VISUAL` if no other focus is present.

UNIX=YES
Specify *YES* to request collection of the z/OS UNIX file directory data from the Hierarchical File System of the current system. This setting is implied by `FOCUS=ADMINRACF`, `FOCUS=ALERT*`, `AUDIT*`, and `TCIM*` and is only supported by these products. If you specify this setting, data collection takes a considerable amount of time. Running APF ensures that all directories can be dumped and makes the process run faster. Also see `UNIXCLIENT` and `AUTOMOUNT`. The userid running CKFCOLL must have an OMVS segment; otherwise the message `CKF320I` with system abend EC6 is issued, or message ICH408I if the default UNIX user exists and is revoked.

UNIXACL=
Use this command to determine whether UNIX ACL entry data is collected.

UNIXACL=NO

Specify *NO* to suppress collection of `UNIX ACL` entries. This value is implied by `UNIX=NO`.

UNIXACL=YES
Specify *YES* to request collection of all UNIX ACL entries. This setting is only honored if `UNIX=YES` is specified or implied, too. This value is implied by `UNIX=YES`.

UNIXCLIENT
Use this parameter to determine whether z/OS UNIX file directory data is collected from the UNIX File System of other systems that are connected through XCF. Generally, you can run CKFCOLL on each system separately which results in a dump of the UNIX File System for each system. Using this method, you do not have to run CKFCOLL through the network to the client, which takes much longer than reading directly from the disk. Because of this situation, the default value for this parameter is *NO*.

UNIXCLIENT=NO

Specify *NO* to prevent collection of z/OS UNIX file directory data from the UNIX File System of other systems that are connected through XCF. That is, this parameter says not to dump UNIX data where the UNIX File System is only mounted as a client. This is the default setting for this parameter.

UNIXCLIENT=YES

Specify *YES* to request collection of z/OS UNIX file directory data from the UNIX File System of other systems that are connected through XCF. That is, this parameter requests to dump UNIX data where the UNIX File System is only mounted as a client.

VMF parameters

Use these parameters to determine whether data is collected from the active TLMS volume master file and to specify the type of data to collect.

VMF=

Use this parameter to determine whether the data is collected.

VMF=NO

Specify *NO* to suppress collecting information from the active TLMS volume master file. It is implied by `FOCUS=ALERT*, TCIM*`, and `VISUAL*` if no other focuses are present.

VMF=YES

Specify *YES* to request collection of TLMS control, volume base, volume link, and data set records from the Tape Library Management System (TLMS) volume master file of the active TLMS system as defined by incore control blocks. This option is implied by the entitlements `FOCUS=ADMINRACF` and `AUDIT*`, and is supported only by these products. If running under RACF with an `AUDIT*` focus but not APF authorized, the program only opens the volume master file automatically if the user has `READ` access to it.

VMFDSN

Use this parameter to include the control, volume base, volume link, and data set data from the specified Tape Library Management System volume master file in the `CKFREEZE` file. It is only supported for entitlements `FOCUS=ADMINRACF` and `AUDIT*`. Also see "Specifying alternate data sources" on page 1597.

The syntax for this command is
`VMFDSN= dsn`
`VMFDSN=dsn/vol`

VTOC

Use the VTOC parameter to determine whether DSCB, VVR/NVR, and ICF catalog information is collected.

VTOC=NO

Specify *NO* to suppress collection of all DSCB, VVR/NVR, and ICF catalog information. This setting implies `VVDS=N,CAT=N`. If no other parameters are specified, this value results in the complete configuration information with the device as the smallest entity plus the contents of any PDS directories and tape/DASD management catalogs implied by the focus.

VTOC=YES

Specify *YES* to request collection of all DSCB and VVR information. The VTOC tracks that contain used DSCBs are read. `VTOC=YES` is the default setting.

VVDS

Use this parameter to control collection of the VVR and NVR information.

VVDS=NO

Specify *NO* to suppress collection of VVR and NVR information. This value is implied by `VTOC=N`. The VVDS data sets are not allocated and opened unless they are needed to obtain information on a tape/DASD management or ICF catalog. If no other parameters are specified, this results in complete

configuration information with the physical data set extent as the smallest entity, but no information is obtained on the cluster name and nature of VSAM physical components. This can result in non-informational system-generated VSAM names in your reports.

VVDS=NONE

Specify *NONE* to suppress collection of VVR and NVR information. This value is stronger than VVDS=N. The VVDS data sets are never allocated and opened. Its main use is to circumvent errors during VVDS processing.

VVDS=YES

Specify *YES* to request collection of VVR and NVR information. The VVDS data sets are opened and the tracks with used control intervals are read. It is the default.

WAIT=NO

Use this non-APF option to determine whether CKFCOLL collects information about retry waits used in attempts to collect data on all physical paths to a device.

WAIT=NO

Specify *NO* to suppress retry waits. Use this value to speed up operation if you are only interested in device contents layout such as VTOC.

WAIT=YES

Specify *YES* (behind an `IF` command, for example) to negate the meaning of a previous `WAIT=NO` statement.

X=list

This parameter is the `EXCLUDE` command. See "Selecting data by device or volume" on page 1599.

XTIOT

The XTIOT parameter manages the behavior of XTIOT control blocks. This parameter can have the following values.

XTIOT=NO

Block the use of z/OS `XTIOT` control blocks for non-VSAM allocations.

XTIOT=YES

Default. Enables dynamic allocation to indicate that z/OS `XTIOT` control blocks are to be used for relief of file allocation limits and below the line virtual storage constraint relief. This option has two prerequisites: Requires z/OS 1.12 support for the `NON_VSAM_XTIOT` PARMLIB option. Requires that the `NON_VSAM_XTIOT=YES` setting is coded in an active `DEVSUPxx` member of the z/OS PARMLIB. If these prerequisites are not met, then `XTIOT=YES` is silently ignored.

3350 (no longer valid)

This parameter is no longer used.

Troubleshooting

For details on zSecure Collect abends that occur during operation, see "Abends" on page 1636. This section lists common abend codes and explains the actions you can take to correct the problem. For other issues, see "Other Problems" on page 1638.

If zSecure Collect operation stops with abend errors, see "Abends" on page 1636 for information about the errors.

Abends

This topic lists the most common abend codes encountered with zSecure Collect. Each abend description also includes suggestions for possible causes and remedies. You can also check the appropriate message manual for your operating system for the exact meaning of an abend and reason code on your system.

001
Usually indicates problems with block size. Look at the message in your job log to determine the ddname.

002
Problems with the DCB parameters of a file. Look at the message in your job log to determine the ddname. Check your specification for DCB parameters with the reference material in "Calling zSecure Collect using JCL" on page 1603.

113-40
This abend with message IEC142I can occur for the `VVDS` or a `CATINDEX`. If the abend occurs for `VVDS`, you are experiencing a problem identified by IBM APAR OW22180. This problem usually starts after service for IBM APAR OW18440 (RLS toleration PTFs) has been applied. You can work around this problem by re-cataloging the VVDSes that cause an abend. If the abend is issued for the `CATINDEX`, then you are experiencing a problem identified by IBM APAR OW23404, which starts happening after applying service for IBM APAR OW22180 (113-40 fix for VVDSs).

When this abend occurs zSecure Collect continues operation with the next dataset on the volume.

213-04
This abend can occur for the VTOC on online volumes that have not been initialized. It can also occur for APF libraries that are not physically present on the volume. zSecure Collect continues operation with the next volume.

213-20
An abend 213-20 can occur on pre-DFP V3 systems if a catalog has more than 16 extents. zSecure Collect intercepts the abend and enters slowdown mode (for example, use VSAM GET, running much slower on shared DASD systems).

322
CPU time limit exceeded. Check the job log for prior abend messages with a different abend code. If a prior abend occurred, solve this abend. Otherwise, increase the `TIME` parameter on the `JOB` card, code fewer functions together, or split the input, specify input per FOCUS for example. Large sites with FOCUS=ADMINRACF or AUDIT* might require a CPU time limit more than a minute on z990 processors. For other sites, a time limit of a minute is normally sufficient. However, if you have specified `CHECK=YES` or have many UNIX files, a time limit of 10 minutes might be required.

522
In the job log, check that the job was not waiting for a tape mount, offline, inaccessible, or reserved device. In the latter case, you can circumvent problems by excluding the inaccessible volume with an EXCLUDE command.

722
Too many output lines. Make your selection more specific or increase the output limit for your job. For example, with a `/*JOBPARM L=`*nn* card, where *nn* represents thousands of lines permitted).

80A, 878
GETMAIN error. Try to increase the REGION parameter on the EXEC or JOB card. If you have reached the maximum size for your site, code fewer functions together, reduce parallelism–by specifying PARALLEL=PATHGROUP for example, or split the input, per FOCUS or per LCU for example. The variable memory usage is slightly more than 64 kB below the line per I/O executor. For the number of I/O executors allocated, see the output from message CKF111I, which is documented in the *IBM Security zSecure: Messages Guide*.

913-0C
An abend 913-0C occurs if attempting to open an unconnected ICF catalog without bypassing RACF data set security. This problem can occur if a selection is done that excludes the master catalog volume, while specifying CAT=YES. If the catalog is in fact connected, then you might be running into a problem caused by IBM APAR OW22180 that starts happening after applying service for IBM APAR OW18440 (RLS toleration PTFs). If this problem occurs, you must also install the fix for IBM APAR OW23404 because otherwise you only change the abend code from 913-0C to 113-40. zSecure Collect intercepts the abend and continues with the next catalog.

913-38
Abend 913-38 occurs if a PDS or other DMS or CA1 non-VSAM data set is opened but you do not have authorization to do so, either through the DATASET profile or through the resource corresponding to your FOCUS (for example, CKF.AUDIT) when running the program with APF authorization.

B37, D37
One of the output data sets was too small, or there was no space left on the volume to extend the data set. Look at the message in your job log to determine the ddname.

DC2
This diagnostic abend is issued by the IARV64 service, which handles storage above the bar. The reason for the abend is explained by the MVS System Code documentation.

EC6
Abend EC6, indicated by message CKF320I can occur under the following condition: The user running zSecure Collect has specified or implied the UNIX=YES setting, the user ID has no OMVS segment, and no default UNIX user ID exists, or there is a default UNIX user ID but it is revoked, or it does not have an OMVS segment. Other EC6 abends can be caused by anything; the abend code indicates that the problem occurred while in a UNIX service. You must have the reason code to know what caused the problem, which might be something like CPU time limit reached - reason FD1D. See the “abend 322” on page 1636 description for details.

User Abends
Generally these abends are accompanied by a high severity message in the SYSPRINT indicating the specific problem and possible solutions. If the SYSPRINT does not include this information, submit an error report to IBM software support.

Most abends (except some I/O related abends) are accompanied by a summary dump. When an error occurs that can be caused by a zSecure Collect problem, submit the following information to IBM software support: The error number, a copy of the summary dump shown in Figure 538 on page 1638, the JCL used, and the listing of the input commands. Figure 538 on page 1638 shows a sample

SYSPRINT log, for a CKFCOLL run that abended. The abend is indicated with a message and followed by a register dump and a traceback.

zSecure Collect prints the offset and CSECT name if the error occurs in a CKFCOLL module. The listing always includes following information: The register contents at the time of abend, a traceback with save areas, the MVS version and a processor name, the last CKFREEZE record written successfully, and the status of some internal control blocks.

Figure 538. SYSPRINT output for CKFCOLL run stopped by abend

Other Problems

The following section describes the CMD rejects problem.

CMD rejects

Sometimes, zSecure Collect causes a number of CMD rejects (unit checks) on a DASD controller (usually one per device on a specific controller). The cause is usually one of the following:

1. The z/OS system is running in a guest machine under z/VM, and the virtual machine does not have the OPTION RMCHINFO in its CP directory entry.
2. The controller tries to emulate an IBM device, but it is not compatible. That is, the controller cannot implement one of the CCWs supported by the actual IBM device. Usually this problem only occurs on OEM devices, sometimes only at specific EC levels. Submit an error report to IBM software support with a specification of the exact controller type, the job log, and the `CKFREEZE` file.

Chapter 17. Setup and Library Commands

Alert	Insight Enabler	Visual	Admin	Audit for RACF	Audit for ACF2	Audit for TSS
•	•	•	•	•	•	•

This chapter describes how to configure the menu settings and run your own zSecure queries. For information, see the following topics:

- "Start Panel - Setting your favorite menu as the entry panel"
- "SE SETUP - Options and input data sets used"
- "CO Commands - Run Commands from Library" on page 1676

Start Panel - Setting your favorite menu as the entry panel

You can specify a panel to open when the product starts. Use this function to start the product at the most convenient panel for users who typically perform a single function or small set of functions.

Note: If the administrator defined a startup panel during the product installation, contact your system administrator to request a change. Typically, users do not have the authority to modify this setting.

To specify the start panel, do the following:

1. On the command line, type `STARTPAN` to open the Start Panel selection panel.

   This panel indicates the current start panel and lists the other option panels available for selection.
2. To change the current setting, type **S** in the selection field for the new start panel.
3. Press **Enter** to apply the selection.

   The next time you start the product, this panel opens in the initial view. To go to the original Main menu, select **Main menu** from the pull-down.

Some panels have a **start panel** field or a **StartPanel** action bar item for selecting the panel as the start panel. If the panel is currently selected as the start panel, the **start panel** field is checked. Remove the selection to reset the start panel to the product default, which is typically the Main menu.

SE SETUP - Options and input data sets used

Use the SETUP menu to customize the settings and options available within Security zSecure. For example, you can select the input files for the zSecure data source and specify processing options for reporting and analysis tasks.

1. To use the SETUP menu, type `SETUP` on the command line or select the SE option from the Security zSecure main menu.

   Note: If you run the SETUP command from within a Security zSecure display, many options do not take immediate effect. They become effective on the *next* Security zSecure query.
2. Press **Enter** to open the menu.

On the SETUP menu, you only see the options you have authorization to use. The **VM Files** option is not shown in a TSO environment.

```

I    Installation    Specify installation defined names
```

Figure 539. Setup Menu

The Setup options described here configure IBM Security zSecure for your own user ID. You can use **SE.D** (Setup default) to configure the interface for groups of users or all users of IBM Security zSecure. This process is described in the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

SE.0 Setup - Run Options

The interactive component of the product keeps settings for this run and subsequent interactive runs in the ISPF profile data set. These options are set and maintained with SETUP option **0**.

```

Server Token   ________
Suppress messages
Message numbers (separated by commas)
____________________________________________________________
```

Figure 540. Setup - Run panel

Use permanent work data sets (CKRCMD is always permanent)
Select this option when you want to use permanent instead of temporary work data sets. For example, when you want to use file-transfer to your workstation. See *Delete permanent work data sets* and *Delete CKRCMD* field descriptions for more information. The CKRCMD data set is always a permanent data set.

Delete permanent work data sets on exit
When **Use permanent work data sets** is selected, the Security zSecure ISPF interface allocates several work data sets for the dialog:

&WORKPREF.C2R*niiii*.CKRCMD
&WORKPREF.C2R*niiii*.CKR2PASS
&WORKPREF.C2R*niiii.CKRTSPRT*
&WORKPREF.C2R*niiii.C2RIMENU*
&WORKPREF.C2R*niiii.REPORT*
&WORKPREF.C2R*niiii.SYSTERM*
&WORKPREF.C2R*niiii.SYSPRINT*

For efficiency reasons, the WORKPREF data sets are not deleted when you are finished with the dialog. Use the **Use permanent work data sets** option when security or space management considerations require that you delete these data sets after leaving the interface. The CKRCMD data sets are only deleted if you select the suboption **Delete CKRCMD on exit** as well.

Note: For additional information about the WORKPREF configuration parameter, see the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

Delete CKRCMD on exit (may contain readable passwords)
Because the CKRCMD might contain sensitive information, only select this

option when Erase-on-scratch is active. Otherwise, a disk scavenger program can find the readable passwords in the tracks of the deleted data.

Allocate CKRCMD data set with RECFM=FB, LRECL=80
Select this option to allocate the CKRCMD data set with RECFM=FB,LRECL=80 instead of RECFM=VB,LRECL=255. For new users, RECFM=FB, LRECL=80 is preselected as the default.

Allocate previous input files at startup
If you select this option, the dialog startup automatically allocates the input data sets you last selected with option SETUP FILES. Otherwise, the installation default allocation is used (if any).

Suppress warning messages when appropriate input files not selected
When an option needs a specific input source such as a CKFREEZE file that is not allocated by the selected set of input files (option SETUP FILES), a message is issued. When a batch run is requested, you can choose to continue the query and allocate the required source via the IBM Security zSecure submit menu (Select an alternate set of input files). If an online query is requested, the option or selection is not selectable. This option can be used to suppress this behavior.

Display of all status messages in sequence (degrades performance)
This option causes all available ISPF status messages to be displayed even though this degrades performance. Normally (off), a status message is only displayed if sufficient time has elapsed since the previous one. This option can be helpful for automated testing or for debugging purposes.

Use TSO SUBMIT (not recommended)
Select this option to call TSO SUBMIT instead of the `C2RSUB` program. Using TSO SUBMIT can result in truncation or continuation problems because that program does not support long records. However, you might want to use TSO SUBMIT because `C2RSUB` does not provide a job card and does not call the site SUBMIT exit.

Suppress call to RACF naming convention exit ICHCNX00
By default, zSecure Admin and Audit calls the system RACF naming convention exit. Selecting this option suppresses these calls. This option can be useful when processing data from another system because the ICHCNX00 of the current system is used, not that of the subject system. This suppression option is not allowed in restricted mode.

Suppress use of RACF naming convention table ICHNCV00
By default, zSecure Admin and Audit simulates processing of the system RACF naming convention exit. Selecting this option suppresses this behavior. However, this suppression is not allowed in restricted mode. Suppressing this option might be useful when processing a database copy or an unload file from another system without a proper `CKFREEZE` file.

Suppress use of RACF range table ICHRRNG
Selecting this option disables use of the system RACF range table. This option is useful if you do not have the proper CKFREEZE file for a RACF database copy, and hence no proper ICHRRNG. You can also consider using this option when you want to find errors in the way a database is split across multiple data sets, errors such as profiles that are defined in the wrong data set, and hence are not used by RACF. Use of this option can lead to *duplicate profile*, *class not in CDT*, and *connect inconsistency*' messages.

Touch RACF connect owner as little as possible
The connect owner field is formally obsolete. If it is not in use for site-specific purposes, consider suppressing its maintenance to improve program

performance. When this option is selected, the program ignores the connect owner field of user profiles during VERIFY PERMIT, REMOVE PERMIT, and MERGE operation. For VERIFY PERMIT and REMOVE PERMIT, setting this option means that zSecure does not generate CONNECT commands to change the connect owner when it is a userid or group which no longer exists.

For MERGE operations, commands are not generated to make the connect owner in the CURRENT database the same as the connect owner in the MERGESOURCE database.

Use ACF2 masking instead of EGN
Use this option to set MASKTYPE to *ACF2*. MASKTYPE sets the way filters are interpreted. The mask type can be *EGN* or *ACF2*. The default is *EGN*. This option is available only when both Admin or Audit for RACF and Audit for ACF2 is installed.

Server Token
Specifies the suffix for the name of the name/token pair that is used to locate the program call (PC) information for a zSecure server. The default value for the server token is PRODSERV. If you specify a value for this keyword, it must be 8 characters or less. Specifying a value for this keyword is required only if you are running multiple zSecure servers on the same system, or if the value for the zSecure server has been changed from its default value.

Suppress messages
You can use this field to suppress messages when they are no longer required to be included in reports. Enter a comma-delimited list of numbers for the messages to be suppressed. You only need to specify the message number, not the full message ID (CKR*nnnn*). Leading zeros are not required.

Suppressed messages do not contribute to the maximum return code.

SE.1 Setup - Input files

As mentioned in “Data Sources” on page 2, IBM Security zSecure processes data from the following sources:

- Data from your security system

  This data set can be the active RACF database, unloaded RACF data, a copy of a RACF database, or an active RACF database from another system.
- Data describing your system configuration (control blocks and DASD)

  This data resides in a CKFREEZE file.
- Data describing events on your system (SMF and other sources)

These data sources must be grouped into **sets** to provide input data for the interactive component of Security zSecure. A **set** is the unit that you can select or unselect for use. Each set can contain one or more data sets. You can create, edit, and delete sets using the Setup Files function. When creating or editing a set, assign the set to a **complex** which represents a group of system images (z/OS or z/VM) that share a security database. Typically, a complex contains that security database and the CKFREEZE files for all or some of the system images that share it. A complex can also contain event data, such as SMF data used for reporting on the events recorded on the systems included in the complex. Event data is only used by the Audit component of IBM Security zSecure. A complex must include at least one input data set which can be a security database, a CKFREEZE file, or SMF event data, but it can contain multiple input data sets.

Note: Information about creating and refreshing an UNLOAD and CKFREEZE data set, see "Refreshing an UNLOAD or CKFREEZE data set" on page 1652 and "SE.2 Setup - New files" on page 1653.

The complex name is used whenever the COMPLEX field is included in queries, on the USER display for example. If the Complex name is not specified, the default value is used. The default value depends on the specified input data source. For data from an UNLOAD operation, the value is the name of the unloaded database. For live data, the default is the name of the live system that is supplying the data. If no unload or live security database is present, a CKFREEZE file is used. In restricted mode (see *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*), a complex name cannot be different from the actual system name that would be used as the default. When not in restricted mode, the complex name can be used as you see fit.

There are three different types of input sets within Security zSecure. Each set has specific rules for changing the field values.

SYSTEM-DEFINED SETS
If no input sets are defined, Security zSecure defines three default input sets for the *active primary*, the *active backup*, and the *active backup + active SMF* input set. You can only delete the default set definitions if other sets have already been defined. The Delete function is available from the **SETUP DEFAULT** option. The default system definitions are restored to the list of available inputs when a **reset to system defaults** action is performed, either implicitly or explicitly.

DEFAULT SETS
You can define default sets for all new users as described in the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*. These default sets can only be changed through the SETUP DEFAULT option, not by the individual user. If default sets are defined, the default definitions are restored to the input data sets when a reset to system defaults is performed, either implicitly or explicitly.

USER SETS
Users can define their own input data sets from the Setup - Input files panel. The user can change the definition for these user-defined data sets at any time. The user-defined input sets are **not** affected when a **reset to system defaults** is performed.

To use the Setup Input option to specify the data sources for zSecure, do the following:

1. Type SE.1 on the command line or select the **Input files** option from the main menu.
2. Press **Enter** to open the Setup Input Files menu shown in Figure 541 on page 1647 .

```
  Menu   Options   Info   Commands   Setup
--------------------------------------------------------------------------------
                        zSecure Suite -Setup - Input files
Command ===> _____________________________________________ Scroll ===> CSR

(Un)select (U/S) set of input files or work with a set (B, E, R, I, D or F)

  Description                                                  Complex
_ Active primary RACF data base                                C##4     selected
_ Active backup RACF data base                                 C##4
_ Active backup RACF data base and live SMF data sets          C##4
_ User defined set                                             testcomp
****************************** BOTTOM OF DATA *********************************
```

Figure 541. Overview of input files sets

The default RACF database shown on the Setup - Input panel is the one that your installer or system administrator specified in the zSecure configuration file. This database might or might not be the active database.

Table 647 provides a list of the line commands available to manage the Input file sets.

Table 647. Setup Input files panel - available line commands

Task	Command	Description
Select an input set for processing	**S**	When you select an input set, the data sets it contains are selected for processing. After the data sets have been located in the system, the set is marked as **selected**. This option is also selected by specifying A. The selected set is an addition to sets already selected.
Remove an input set from selection	**U**	When you remove the selection from an input file set, the data sets are not used in future queries.
Browse a set of input files	**B**	Check the definitions for the set. When you exit the detail panels, the set is not selected.
Edit the data sets included in an input set.	**E**	When you enter this command, the list of data sets included in the input set are displayed so you can change them. If you press **F3** or enter `END` on the Edit panel, the set is marked as **selected**.
Copy the contents of an existing input set to a new input set.	**R**	Repeat a set. The contents of the set you choose are copied into a new set. The new set is shown. If you press **F3** on the panel showing the new set, it is selected for processing as if you had entered the **S** line command.
Insert a new input set.	**I**	Opens a new input file set where you can add the desired data sets to be included as input sources. After you enter the data set information and press F3, the new input set is selected for processing.
Delete a data set.	**D**	Removes an input set entry or a data set entry in the input set definition. The name and associated information are removed from the view. However, the data sets in the set are not deleted from the system. The D line command is not available for system defined and default sets.
Refresh the data sets included in the input set.	**F**	Entering this command opens a panel that allows you to submit a job to refresh the contents of the data sets. The **F** line command is not available for system-defined and default sets.

You can select multiple input sets for processing. The input sets can be associated with the same complex or with different complexes. However, for any complex in the combined sets, you cannot have more than one security database, be it active primary, backup, or unload.

To exit the Setup Files function, you can either press the **END** key, the **PF3** function, or enter the **CANCEL** command. Using the end key, saves the current settings in your ISPF profile. When you exit, a message is displayed indicating which complexes are selected. The selected input complexes are also displayed at the bottom of the main menu.

When you edit or create an input file set, the panel shown in Figure 542 opens:

```
   Menu   Options   Info   Commands
--------------------------------------------------------------------------------
                        zSecure Admin and Audit - Setup - Input files
Command ===> ____________________________________________________ Scroll ===> CSR_

Description . . . . Your description for this set of input files
Complex . . . . . . ________   Version  . . . .  ____
RRSF node . . . . . ________   Local node for RRSF

Enter data set names and types.         Type END or press F3 when complete.
Enter dsname with .* to get a list      Type SAVE to save set, CANCEL to quit.
Valid line commands: E I R D            Type REFRESH to submit unload job.

Data set or DSNPREF= or UNIX file name                    Type        NJE node
_ ____________________________________________________ ___________ ________
****************************** Bottom of data ********************************
```

Figure 542. Initial view of an input file set under z/OS

On this panel, you can add data sets or files for the specified input set. You can enter data set names with or without quotes. The TSO PREFIX is put in front of an unquoted data set name. Trailing quotes are automatically supplied. Generation data sets in relative notation and full GDGs are supported. For a full GDG, you can specify the GDG base name without any member selection. This specification concatenates all data sets belonging to the GDG. Full GDGs cannot be used for security databases or CKFREEZE data sets.

When using relative GDG data sets or full GDGs, make sure that you understand the serialization effects. For example, MVS guarantees that `YOUR.GDG(-1)` refers to the same data set throughout your job or session. Consequently, after you have allocated a relative or full GDG to your zSecure session, a job that tries to create a generation can fail or wait until your session has finished.

To allocate all data sets with a specified High-level qualifier, specify the value for the qualifier in the **DSNPREF** field. For example, if you specify `DSNPREF=SYS1.DAILY.SMF` all data sets that are allocated begin with the High-level qualifier `SYS1.DAILY.SMF`. The last qualifier specified is interpreted as a partial qualifier. If you want to match only full qualifiers you have to end the `DSNPREF` value with a period. The `DSNPREF` parameter value is resolved immediately before reading the data which can result in having different data sets allocated each time. As a result, the Setup Input transaction does not test for missing or migrated `DSNPREF` data sets.

If you specify the `DSNPREF` parameter, you cannot specify values for the `UNIT` and `VOLUME` fields.

Instead of OS data set names, you can use UNIX path names. When you want to allocate SMF log streams you enter the log stream name here, optionally followed by a SUBSYS parameter. For example, to get all records from Oct 15, 2007, you can use the following specification:

```
IFASMF.MAIN('FROM=(2007/288),TO=(2007/288),LOCAL')
```

The input field only allows 55 characters. If you need more, you must code the CARLa ALLOC statement yourself. For additional information, see "ALLOCATE" on page 718 and the *z/OS MVS JCL Reference*.

On this panel, enter file names according to ISPF standards. To search for files, specify a file name ending in `.*`. Then press **Enter** to display the matching filenames. On the resulting display, you can remove the entry for the generic specification (`.*`) and any other files that you do not need by entering the `D` line command. The delete command does not delete the data set, it just removes the name and information from the display.

This **Version** field can be used to classify the data allocated into separate sets like OLD and NEW. This value is different than the COMPLEX value, which is used to identify the systems with a shared security database that are the source of the data. You can use the VERSION specification to analyze data in the same COMPLEX at multiple points in time.

Many reports only show 8 characters of the complex name, which does not include the VERSION identifier. If you use the same COMPLEX name, you cannot use the report to identify the data from different versions.

To insert a new data set, use the **I** line command.

On the panel in Figure 541 on page 1647, you can also specify the **Type** for the input data source. Table 648 lists the available data set types.

Table 648. Input Files: available data set types

If you want to use...	use TYPE...	Notes
The primary RACF database of your active system	`ACT.PRIM`	2 8
OS RACF database	`COPY.RACF`	8
The live SMF data sets	`ACT.SMF`	2
The backup RACF database of your active system	`ACT.BACK`	1 8
An unloaded security database	`UNLOAD`	
A copy of a single-dataset RACF database (for example, restored, or from a different system image)	`COPY.RACF`	8
A copy of a multi-dataset RACF database (for example, restored, or from a different system image)	`COPY.TEMP`, `COPY.SEC`	3
Live settings	`ACT.SYSTEM`	4
A CKFREEZE data set	`CKFREEZE`	
VSAM or dumped SMF	`SMF`	5
SMF log stream	`SMF.LOGSTR`	5
An ACCESS monitor data set	`ACCESS`	Admin only

Table 648. Input Files: available data set types (continued)

If you want to use...	use TYPE...	Notes
The access log of a webserver	WEBACCESS	Audit only
The error log of a webserver	WEBERROR	Audit only
Other event logs	<deftype>	6
A file for generated RACF commands	CKRCMD	7

Notes:

1. The data set name for the RACF database is not required.
2. Audit only. The data set name is not required.
3. Sequence is important for a multi-dataset RACF database. In ICHRDSNT, the first data set of the systems where this is or was the active database must have type COPY.TEMP because that data set contains the RACF templates that are used on that system. The other data sets have type COPY.SEC, and must be specified in the same order as in ICHRDSNT.
4. If you process multiple complexes and *complex A* does not contain a CKFREEZE data set while *complex B* and *C* do, *complex A* inherits one of the available CKFREEZE data sets from *complex B* or *C*. This inheritance causes unpredictable results. The ACT.SYSTEM type authorizes you to explicitly tell the program to use the current live settings for this complex instead of the settings from a CKFREEZE data set.
5. Audit only. Intermediate data sets from RACFRW or the IRRADU00 SMF unload program are not supported.
6. You can use the **SE.U** option to create your own types of data sources. For details, see "SE.U SETUP - user-defined input sources" on page 1667. You can use the DEFTYPE name assigned to your data source using the SE.U function as the **Type** on the **SE.1** menu.
7. Admin only. This file is used for output. If you do not supply a CKRCMD file, a work file is created as needed. If you create it yourself, it must be a sequential data set with record format FB and record length of 80 bytes, or a sequential data set with record format VB and record length of 255 bytes. Any previous content is overwritten. After commands have been generated here, you have options to run the commands, save them, submit a job, and so on.
8. Using a RACF database that is in active use (either as database of the life-of-job system, or as a foreign database) incurs the risk that the database is updated by RACF while zSecure is reading the database. To avoid this risk, use an UNLOAD data set.

When not certain of the Type, you can enter a question mark in the **Type** column. Then, press **Enter** to display a list of supported types as shown in Figure 543 on page 1651.

```

****************************** Bottom of data ********************************
```

Figure 543. File type menu for Setup files

On the panel shown in Figure 541 on page 1647, you can select the type that applies to your input. Press Enter to return to the previous screen.

You can also specify an NJE node to refresh the UNLOAD data set and/or CKFREEZE data set. Refresh needs to run on a system that the to-be-refreshed data pertains to. For an UNLOAD data set, this value can be any of the systems that share the security database. For a CKFREEZE data set, the refresh must run on the system that is described by the CKFREEZE data set. If the target NJE node is a Multi-Access Spool node, you also need to specify the system within that node. To specify the system for the node by use the **E** line command on a data set

```

Function  . . . . .   1. Main     2. Base
****************************** Bottom of data ********************************
```

Figure 545. Specifying data sets details within a set of input files

This same panel can also be used to access non-cataloged data sets. This function is not supported for VSAM or SMS-managed data sets.

On the panel in Figure 541 on page 1647, you can also specify an RRSF (RACF Remote Sharing Facility) node. This field indicates the node used in command generation. It is directly related to the Complex field. The RRSF node can be defined using the Edit line command on the Setup - Input Files panel.

You can also specify the name of remote **zSecure Node** and the name of the remote **zSecure System**. See *Multi-System Support* for more information.

In addition, you can specify a value for the **Function** field:

1. Main
For UNLOAD files, this value indicates that the database is to participate normally in VERIFY and REPORT commands. This setting is the default used if the Function field value is not specified.

2. Base
Select this option to automatically activate compare mode for detecting and reporting on changes in selected fields. All identical records from different complexes are suppressed. This specification works best when multiple data sets for different complexes are used. Only one data set of the same TYPE can specify function=base. See "Compare processing" on page 46.

Note: If two or more ALLOC statements specify the same COMPLEX but one has FUNCTION=BASE the other cannot have FUNCTION=MAIN.

Refreshing an UNLOAD or CKFREEZE data set

On the Setup - Input Files panel (Figure 541 on page 1647), enter the **F** line command to refresh an UNLOAD or CKFREEZE data set. When you enter the command, zSecure generates a batch job and opens a panel to submit the job. You can browse or edit the batch job, or include the generated job in your production schedule.

When the job runs under a system other than your local system, it is assumed that an NJE connection is in place. If an NJE connection does not exist, capture the job and transfer it using another method. It is also assumed that you have shared DASD which means that the data refreshed on the target system is immediately available on your local system. If you do not have shared DASD, use another method to transfer the refreshed data back to your local system.

SE.2 Setup - New files

This function can be used to create and fill new UNLOAD and CKFREEZE files. You can set up these data sets on the panel shown in Figure 546.

```
 Menu   Options   Info   Commands
-------------------------------------------------------------------------------
                        zSecure Suite - Setup - New files
Command ===> ____________________________________________________________________

Create new unload file from the RACF database and CKFREEZE file

Dataset with unload from RACF database, use UNLOAD as last qualifier
 Unload . . . . . myname.unload_____________________________

I/O configuration file, use CKFREEZE as last qualifier
 Ckfreeze . . . . . myname.ckfreeze_____________________________

Description for this set of input files
 Description  . . . private set of unloaded files_____________________

Enter data set names and description and press ENTER
******************************* Bottom of data ********************************
```

Figure 546. Setup - New files panel

Data set names must conform to TSO conventions. Use quoted data set names if needed. Use *UNLOAD* or *CKFREEZE* as the last qualifier in the data set name, as shown in 1653. If you use these qualifiers, the **SETUP FILES** (**SE.1**) function automatically recognizes the types. When you press Enter, the program checks to determine whether each data set is cataloged. If a data set cannot be found, the allocation entry panel is displayed.

```
 Menu   Options   Info   Commands
-------------------------------------------------------------------------------
                        zSecure Suite - Setup - New files
Command ===> ____________________________________________________________________

CKFREEZE file not found. Change dataset name, or specify allocation parameters

 Dataset name . . . MYNAME.CKFREEZE_____________________________

Allocation parameters to create new dataset:
 Volume serial  . . ______      (Blank for authorized default volume)
 Generic unit   . . ________    (Generic group name)
 Space units  . . . _____       (KB, TRKS, or CYLS)
 Primary quantity   ________    (In above units, press HELP for suggestion)
 Secondary quantity ________    (In above units)

 Record format  . . VBS__       (VB or VBS)
 Block size   . . . 27998__
 Logical Record Len X______     (X or maximum record length)

Press ENTER to allocate dataset, press END to stop processing
```

Figure 547. Setup - New Files Allocation Entry panel

Specify sufficiently large space parameters for new data sets. Recommended values are:

CKFREEZE
2 megabyte per on-line DASD volume

UNLOAD
Specify a value equal to the size of your RACF database

After the data sets have been created, they are put into a set, and Figure 544 on page 1651 will be shown, inviting you to enter the REFRESH command on the command line. This procedure is described under "SE.1 Setup - Input files" on page 1645. You can start using the new set once the REFRESH job is successfully completed.

SE.3 Setup - Preamble

Use the PREAMBLE function for setting up common commands used in every action or query. For example, if your installation considers **all** link list data sets sensitive instead of just the APF data sets, you can add a SIMULATE SENSITIVE LINKLIST statement to every run. The PREAMBLE provides a simple way to customize the product. You can add an INCLUDE command in the preamble to add a user or installation-defined member to every run.

You specify the preamble commands from the Setup - Preamble panel shown in Figure 548.

```
 Menu   Options   Info   Commands
--------------------------------------------------------------------------------
                        zSecure Suite  - Setup - Preamble
Command ===> ____________________________________________________________

_  Execute preamble commands before every query

Enter CARLa commands below (no conversion to UPPER case):
>
> ____________________________________________________________________________
> ____________________________________________________________________________
> ____________________________________________________________________________
> ____________________________________________________________________________
> ____________________________________________________________________________
> ____________________________________________________________________________
> ____________________________________________________________________________
> ____________________________________________________________________________
> ____________________________________________________________________________
> ____________________________________________________________________________
> ____________________________________________________________________________
> ____________________________________________________________________________
> ____________________________________________________________________________
> ____________________________________________________________________________
> ____________________________________________________________________________
```

Figure 548. Setup - Preamble

To use the preamble commands each time a query is run, select the **Execute preamble commands before every query**.

Execute preamble commands before every query Use this option for including the Commands entered on the Preamble panel in every call to the program. You can temporarily disable the Preamble function by removing the selection (/) from the **Execute preamble commands before every query** on the panel. If no commands have been specified, this field is not selected.

For more information, see "Using the Preamble function."

Using the Preamble function

This example shows how to suppress a user or group ID on the profile displays. In this case, the user or group ID is one that is included on the access list for all DATASET or general resource profiles in your installation.

You can use the following PREAMBLE statement to accomplish this task:

```
DEFINE ACL SUBSELECT,
       ACL(ID<>(IBMUSER,SYSAUDIT) OR ACCESS<>ALTER)
```

The statement can be defined in a PREAMBLE statement, either individually on the Setup - Preamble panel, or using the Setup Default function available on the Setup menu.

This statement redefines the ACL output variable to show only access list entries that do not specify the *IBMUSER* or *SYSAUDIT* IDs with an access level of ALTER. If one of these IDs has another access level it is shown. This modified ACL output variable is used in all displays where the variable is not redefined again.

Notes:

1. The ACL redefine does not influence the REPORT command. Reports produced from option **3** still contain the suppressed IDs.
2. Commands generated to clone data set profiles by typing a *C* in front of a profile use the ADDSD XXX FROM(YYY) construction. In this case, the new profile contains the same access list as the original profile, plus the user ID used to run the command.
3. Only the **ACL**, **CONNECTS** and **USR** fields can be redefined in this way. For more information, see "DEFINE" on page 750.

SE.4 Setup - Confirm

Use the Setup Confirm option to specify command execution options. These options specify:

- How commands are executed, for example, immediately or queued.
- How you are prompted for command routing information.
- If generated commands must be confirmed before execution.
- If certain field values can be modified, if authorized.
- Which types of commands can be generated.

Note that some options can also be set from within a display panel using the SET command.

```

```

Figure 549. Setup - Confirm

Action on command

Use this field to specify what actions to take for the line commands and overtypes. For example, you can specify whether to write the commands generated by line commands and overtypes to an output file or run them immediately. Table 649 lists the available options.

Table 649. Setup - Confirm panel - Action on command options

Action setting	Description
Queue	TSO commands are written to an output file (CKRCMD) for later use.
Execute	TSO commands are run immediately after confirmation.
Not allowed	For zSecure Admin, users cannot issue line commands and fields cannot be modified from the interface. For zSecure Audit, line commands cannot be used.
Execute display commands (for Queue setting only)	For display or list commands only, such as LISTUSER, PING, TRACERTE, and RLIST, select this option to execute list commands for the Queue action setting. The option to override the queue setting and execute list commands applies to generated list commands only and does not change the execution of any list commands that you enter. For example, a list command entered with the FORALL command is not effected by this option.

If a single command is generated, for example, when you change a value on a display panel, or use certain line commands, zSecure can be set to display a confirmation panel showing the generated command. If multiple commands are generated, for example, when you use the Copy or Recreate line command, zSecure does not display a confirmation panel. In this case, if confirmation is set to All or Delete and Action is set the Execute, zSecure queues the commands so that they can still be confirmed.

If Action is set to queue, or zSecure queues multiple output commands because Action is set to Execute, the generated commands are written to the CKRCMD

command file. See “A sample run” on page 17 for an example. When you exit the display panel, the CKRCMD file is displayed in an EDIT session. You can then inspect the generated commands and change them to meet your site requirements.

When you exit the edit session, the Results panel is shown. See “A sample run” on page 17 for an example. This panel provides the following options:

- Run the commands.
- Write them to a file.
- Submit the commands, possibly to a different system image.
- Discard the commands.

Notes:

1. Commands generated from the **Quick User Administration (RA.Q)** option are always executed directly.
2. In zSecure Admin, creating a profile or segment also bypasses confirmation. The confirmation settings apply only to the dialog that updates the profile or segment that was created.
3. If the commands contain line commands on profiles, the commands are queued for CKR2PASS and are not always automatically shown on the Results panel. You can view or edit these commands from the Results panel, unless you have set the Confirmation option to None. In this case, the CKR2PASS output is immediately run as a second-pass CARLa. (For information about CKR2PASS commands, see “RESULTS - View output and results” on page 24.)

Confirmation

In zSecure Admin, this option determines if commands that are generated must be confirmed before they are queued or run. Table 650 describes the available options.

Table 650. Setup - Confirm panel - Confirmation command options

Confirmation setting	Description
All	Commands must be confirmed.
Delete	Only commands that perform a delete action must be confirmed.
Password	Commands with a readable password or password phrase must **not** be confirmed.
None	Commands are never confirmed.

Command Routing

The three routing levels are:

Ask

This option sets the maximum prompting level. For all commands or command files, the user is prompted for command routing information. This setting applies to commands generated for the local system, as well as for commands generated from data sources that are known to be from other systems.

If Command Routing is set to **Ask**, you are asked to select command destinations before the command is executed. For more information, see “Command routing” on page 28.

Normal
This is the default prompting level. Commands are run without prompting for command routing options. Confirmation prompting and command queuing is done according to the user settings. If you want to queue commands instead of executing them, choose the Queue option on the Confirmation panel that displays at during program operation. If the RACF data source applies to the local system, commands are routed to the local system. The user can specify remote options for the following local data sources: RRSFNODE, ZSECNODE , or JESNODE). These remote indicators are ignored for a local data source. If the commands are not for the local system, they are routed to one of the following systems in order of preference:

1. The zSecnode or the zSecsys as specified by the RACF data source used for this profile.
2. The node specified in the RRSFNODE for the RACF data source used for this profile. The command uses the AT keyword, specifying either the current userid or the associated userid if the terminal user has an association with a userid on the target RRSFNODE.
3. The JES node specified for the RACF data source. If a specific routing mechanism is selected and fails, there is no automatic fallback to another routing mechanism.

Local only
This is the old method of command routing. The command is routed to the local system independent of the input source. If the local system is part of an RRSF autocommand environment, RRSF processing might route this command to other RRSF nodes.

Command Generation
The following options determine how commands are generated and processed.

Overtype fields in panels
Check this option to provide the option to type over values in fields on a display panel. Changing field values generates RACF commands to complete the change in the RACF database.

Change generated commands
This option specifies whether you are allowed to change commands after they have been generated. If a change is required to complete the command, this option is ignored. For example, if you run a Copy command on a profile, a change is required. The user must specify a name for the profile copy before saving it.

Specify start/end date
If this option is checked, you are prompted for a start and end date when generating CKGRACF commands.

Generation SETROPTS REFRESH commands
If selected ("/"), this option specifies that SETROPTS REFRESH commands can be generated. If it is not selected, the refresh command generation is suppressed.

Note: If SUPPRESS SETROPTS REFRESH is specified in the Preamble, this option is ignored. For more information, see "SE.3 Setup - Preamble" on page 1654 and "SUPPRESS" on page 932.

Issue prompt before generating SETROPTS REFRESH commands
If this option is selected ("/"), the *Action on command EXECUTE* is in effect. As a result, and SETROPTS REFRESH commands are generated. You are

prompted to decide whether to issue the commands. If this option is not selected, the prompt for the SETROPTS REFRESH command generation is suppressed.

Commands to generate
The following options determine which commands can be generated.

RACF commands
This option specifies that RACF commands can be generated when a command is run. If there are other command types, you are prompted to specify your preference for command generation.

CKGRACF commands
This option specifies that CKGRACF EXECUTE commands are generated if required. The only advantage of using this option instead of the *RACF commands* option is that you can specify a REASON that is written to SMF together with the command in an extra audit record.

CKGRACF ASK for later execution
Use this option for generating the `CKGRACF ASK`[24] command so it can be submitted for processing at a later time.

CKGRACF REQUEST for later execution.
This option specifies that a CKGRACF REQUEST command can be generated.

CKGRACF WITHDRAW queued commands [24]
This option specifies that a CKGRACF WITHDRAW command can be generated.

CKGRACF RDELETE commands
This option specifies that a CKGRACF RDELETE command can be generated when a delete action is requested for a DATASET or general resource profile.

SE.5 Setup - View

Use the view menu to specify the amount and appearance of the data presented to you. The access list settings can also be set from a display panel using the `SET` command.

24. For details on the exact meaning of and differences between CKGRACF EXECUTE, ASK, REQUEST, and WITHDRAW commands, see "CMD" on page 1505.

```
 Menu  Options  Info  Commands  Setup
------------------------------------------------------------------------------
                     zSecure Suite - Setup - View
Command ===> ____________________________________________________________

 Access list format . . . . 2  1. No       3. Explode  5. Effective
                               2. Sort     4. Resolve

 ACL/Connect sort . . . . . 2  1. Id       2. User     3. Access
 Show OS specific options   /  z/OS        _  z/VM
 /  Add user/group info to view
     (Selecting this will use some additional storage - normally on )
 /  Add summary to RA displays for multiple complexes (normally on)
 _ Add connect date and owner to RA.U connect group section

 Select view
 3  1. View only profiles you are allowed to change (administrator view)
    2. View all profiles you are allowed to change or list
    3. View all profiles (normal view)
```

Figure 550. Setup View Panel

Access list format

Determines the layout of access lists fields. Select 1. No to suppress the access lists. Select the SORT to sort the access list.

Table 651. Setup - View panel - ACL list field layout options

Action setting	Description
EXPLODE	Display the access list in sorted and exploded format. When this option is selected, the view includes information about all possible ways the user has access.
RESOLVE	Display the access list in sorted and resolved format. This layout only includes the most specific way that a user has access in the view.
EFFECTIVE	Also shows users that are not on the access list but have access due to operations or group operations privileges. Specifying `EFFECTIVE` switches on full database read instead of indexed access, which can result in increased query response time. Although full database read is turned on, you still might not be able to see all connects and operations users. Some information can be missing if universal group connects are not fully expanded. To guarantee that all access is shown for the RA.D or RA.R functions, use the Enable full ACL option.

Use the `SORT` value for the Access list format. This configuration enables the C line command as well as permitting you to change the values in the access list entries without significantly increasing query response time.

ACL/Connect sort

This option determines the sort order of access list and connect displays. The sort order is used with the `SORT`, `EXPLODE`, `EFFECTIVE`, and `RESOLVE` options. The following table lists the possible values for this option.

Table 652. Access List and Connect displays: Available sort orders

Value	Description
ACCESS	Sort by access level, from `ALTER` to `NONE`. For connects, `ACCESS` means sort by the following descending access settings: non-revoked, group-special, group-operations, group-auditor, and join, connect, create, and use authority.

Table 652. Access List and Connect displays: Available sort orders (continued)

Value	Description
ID	Sort by unresolved, unexploded access list `ID`. For connects, `ID` means sort on the `ID` in the connect list.
USER	Sort by exploded or resolved access list `ID`. For connects, `USER` means sort on the id in the connect list.

Show OS specific options
With this option you can switch between z/OS and z/VM specific options, or tag both to see all options.

Add user/group info to view
When this option is selected, the display panels for user profiles and group profiles includes information about users and groups on access list and connect displays. Selecting this option does increase the amount of virtual storage being used because of the added user and group information. If this option is not selected, the options for issuing **C** (Copy) line command and modifying the connect and access list information are not available. Leave this option selected unless you have severe memory constraints.

Add summary to RA displays for multiple complexes
When this option is selected, an extra summary section is added to the display panels for the following options RA.U, RA.G, RA.D, and RA.R. The summary information shows profile differences when multiple complexes are selected. This setting is not saved in your ISPF profile. This option is enabled by default.

Add connect date and owner to RA.U connect group section
Use this option to add the connect date and connect owner to the RA.U connect group section.

Select view
Use this option to specify which profiles are displayed.

- **View only profiles you are allowed to change** requests to show only profiles that you can modify.
- **View all profiles you are allowed to change or list** requests to also show profiles in your CKGLIST scope or within your group-AUDIT authority.
- **View all profiles** is the typical, most efficient view option because it saves storage and CPU time. If you are not running in restricted mode, setting this option can make a noticeable difference in response time and storage requirements.

SE.6 Setup - Instdata

Use the Setup `Instdata` option to maintain `instdata` mappings. After you have added an `instdata` definition set, you can specify different `instdata` mappings for the USER, GROUP, DATASET, and RESOURCE classes. You can use the defined fields for creating an output layout. Different layouts can be created for the overview and detail displays as well for the print formats.

1662 shows a table of `instdata` definition sets:

```
 Menu  Options  Info  Commands  Setup
------------------------------------------------------------------------------
                     zSecure Suite - Setup - Instdata     Row 1 to 2 of 2
Command ===> _____________________________________________ Scroll ===> CSR

Select INSTDATA definition set ( S (select), U (unselect),
E (edit), I (insert) or D (delete))

    Name       Description
_   PROD       Production LPAR                          Active set
------------------------------------------------------------------------------
_   DEV        Development LPAR                         _________
------------------------------------------------------------------------------
****************************** Bottom of data ********************************
```

Figure 551. Setup Instdata panel

You can use the following line commands on this display:

Table 653. Setup Instdata panel - available line commands

Command	Description
S	Select a predefined `instdata` definition set. This sets the **Active set** indicator. The output layout of the RA options is defined based on the selected definition set.
U	Unselect a selected `instdata` definition set. When no set has the **Active set** indicator, the `instdata` is displayed as is.
I	Insert a new `instdata` definition set to specify mappings and output layouts.
E	Edit an `instdata` definition set to specify mappings and/or output layouts.
D	Delete an `instdata` definition set.

The first time **SETUP Instdata** is selected, or after issuing the **I** (insert) line command, the panel shown in Figure 552 is displayed.

```
 Menu  Options  Info  Commands  Setup
------------------------------------------------------------------------------
                     zSecure Suite - Setup - Instdata
Command ===> ____________________________________________________________

Enter INSTDATA definition set name for new instdata layout mapping
Name  . . . . . . . . . ________                (INSTDATA definition set)
Description . . . . . . ________________________________  (optional)
```

Figure 552. Setup Instdata- Definition set name

After specifying a unique Instdata definition set name, or after issuing the **E** (edit) line command for an existing set, the Class selection panel is displayed:

```
 Menu  Options  Info  Commands  Setup
--------------------------------------------------------------------------------
                     zSecure Suite - Setup - Instdata     Row 1 to 4 of 4
Command ===> _____________________________________________ Scroll ===> CSR

Select( S ) the class you want to maintain INSTDATA mapping for

-------------
    Class
S   USER
_   GROUP
_   DATASET
_   RESOURCE
****************************** Bottom of data ********************************
```

Figure 553. Instdata Setup - Class selection panel

The class selection display is used to select the class for which you want to maintain an `instdata` mapping and output layout definitions. When a class is selected (by the **S** line command), the `instdata` mapping definition panel is displayed:

```
 Menu  Options  Info  Commands  Setup
--------------------------------------------------------------------------------
                     zSecure Suite - Setup - Instdata
Command ===> ____________________________________________________________

Instdata mapping definition

_  Concise print output             _  Detail print output
_  Concise narrow print output      _  Detail narrow print output
```

Figure 554. Instdata Setup - Mapping definition

You can use this panel to maintain the `instdata` mapping for the selected class.

The following fields are available on this panel:

Table 654. Instdata Setup - Mapping definition field descriptions

Field	Explanation
Field name	The field name. The field name must be unique for the selected class and must not be the same value specified in a predefined field name. This field is required.
Default output header	Specifies the header that is used when no overriding header is specified on the output layout definition panel. When no default output header is specified, the field name is used.
Pos	Indicates the start position of the field within the `instdata`. This field is required.
Len	Indicates the length of the field within the `instdata`. This field is required.

Table 654. Instdata Setup - Mapping definition field descriptions (continued)

Field	Explanation
Format	Specify an output format, HEX or NUM for example. The default output format is CHAR (as it is for `instdata`).
Output layout definition	Select one or more reports to maintain the output layout definition for.

Selecting one or more output layout definitions opens an additional panel so the output layout can be specified.

```
 Menu  Options  Info  Commands  Setup

```

Figure 555. Instdata Setup - Mapping definition output layout

The following fields are available on this panel:

Table 655. Instdata Setup - Mapping definition output layout field descriptions

Field	Explanation
N	Checkbox that indicates if the field is displayed on a new line. The checkbox is not available for the *display overview* and *concise print output layout* definitions.
Field name	The name of the field to be displayed. The field must have a corresponding definition.
P	This checkbox can be selected to indicate if the field value is prefixed with the header. The checkbox is not available for the *display overview* and *concise print output layout*.
Header	This header for this field. If this value is specified, the value overrides the default output header. When no header is entered, the default output header is used.
Len	The length for this field. If this value is specified, it overrides the default length as specified on the `instdata` mapping definition panel.
Output modifiers	On this field you can enter one or more output modifiers, separated by commas. See "General output modifiers: Controlling field-related output" on page 798 and "Display modifiers: Changing field output display in ISPF" on page 802 for valid output modifiers.

When you exit the Setup Instdata panel and enter `RA.U` option, the detail display shows the `instdata` that you have specified. Figure 556 on page 1665 shows an

example of the panel.

```

SE.7 Setup - Output

You can use the Setup Output option to specify settings for generating output like the page and line length and the printer options. These options affect the P (print) line command on the Results panel. The settings are also reflected in the generated JCL. They have no effect on the behavior of the PRT primary command.

```

Figure 557. Setup Output panel

The descriptions for the fields available on this panel are provided in the following list.

Report Options

Pagelength
Sets the page length for use in printable reports. A page length of 0 suppresses all but the first occurrence of the page header and column headers. The maximum value is 32760.

Linelength
Sets the useful line length of the output data sets for later runs. The DCB LRECL value for the data set is set to the value of linelength + 4. The LRECL for the current run is not affected. Information about the output might be lost if the value is too small. The minimum recommended value is 133.

Convert all printed output to uppercase
Specify that all output is to be listed in uppercase, instead of mixed case.

Print options

The Print options fields can be used to specify the (TSO PRINTDS command) options for printed output.

Destination
Specifies the destination to which the output is routed for final processing. The destination is in the form: **destination.userid** or **destination**, where the destination and the userid are 1 - 8 characters. For further information about the TSO PRINTDS command (DEST operand), see the TSO/E Command Reference.

Sysout class
Specifies the JES output class to be used for the output processing of this data set. Default is output class A. For further information about the TSO PRINTDS command (CLASS operand), see the TSO/E Command Reference.

Writer id
Specifies a name for use in processing or selecting a SYSOUT data set. For further information about the TSO PRINTDS command (WRITER operand), see the TSO/E Command Reference.

Copies
Specifies the number of original copies to be printed for the data set. The value for copies can be within the range from 1 to 255. For further information about the TSO PRINTDS command (COPIES operand), see the TSO/E Command Reference.

Character set
Specifies the names of the character arrangement table. For further information about the TSO PRINTDS command (CHARS operand), see the TSO/E Command Reference.

FCB
Specifies the forms control buffer or image used. For further information about the TSO PRINTDS command (FCB operand), see the TSO/E Command Reference.

Forms
Specifies that the output data set is to be printed on a special output form. This value must be from 1 to 4 alphanumeric or national characters. For further information about the TSO PRINTDS command (FORMS operand), see the *TSO/E Command Reference*.

Output descriptor
Specifies a list of output descriptors for the SYSOUT data set. For further information about the TSO PRINTDS command (OUTDES operand), see the *TSO/E Command Reference*.

Forms overlay
Identifies the name of the forms overlay to be used. For further information about the TSO PRINTDS command (FLASH operand), see the *TSO/E Command Reference*.

SMTP options
Ask your system programmer for the correct settings for these options.

SMTP node
Specifies the NJE destination where email is routed for final processing.

SMTP sysout
Specifies the JES output class to be used for the SMTP output processing of emails.

SMTP writer
Specifies a name for use in SMTP selecting an email SYSOUT data set. The external writer name is equal to the SMTP address space name.

SE.8 Setup - Command files

Although all Setup functions can be set individually, the Setup Command files option can apply system-wide or to a group of users, as a suboption under Setup default. See the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*. When set individually, the SE.8 menu option is equivalent to option `CO.1`. For additional information about the option, see "CO.1 LIBRARIES - Data set selection" on page 1676.

SE.U SETUP - user-defined input sources

This option allows you to define `NEWLIST` types by using `DEFTYPE` (see also "DEFTYPE" on page 777). Actually it allows you to specify a member that contains the `DEFTYPE` and any relevant `DEFINE` statements. When you enter this option initially, the following panel is displayed.

```
         Menu  Options  Info  Commands  Setup
--------------------------------------------------------------------------------
                          zSecure Suite - Setup - User defined
Command ===> ____________________________________________________________________

Enter DEFTYPE data definition

Deftype . . . . . . . . ____________________
Description . . . . . . ____________________________________________
Abbreviation  . . . . . __
Data set name(member)   ____________________________________________________
```

Figure 558. Setup user-defined input sources panel

The following fields are available for setting up user-defined input sources:

Deftype
Name of the NEWLIST type.

Description
The description of this type of `NEWLIST`.

Abbreviation
A two character abbreviation for this `NEWLIST`. This abbreviation must be unique for every `NEWLIST` type. It is used for ddname generation.

Data set name(member)
The data set name and member of the define statements.

After all fields are entered, press **`END`**. The results are shown in a table display.

```
        Menu  Options  Info  Commands  Setup

                    zSecure Suite - Setup Change Track
Option ===> ____________________________________________________________

D    Data sets       Maintain list of sensitive data sets
M    Site msgs       Site defined message table
C    zSecure msgs    zSecure defined message table
```

Figure 560. Setup Change Track panel

Table 657 describes the options available from this menu.

Table 657. Setup Change Track menu options

Change track option	Descriptions
D	Manage data sets your site considers sensitive. See “SETUP - Change Track Data Sets” on page 1669.

Table 657. Setup Change Track menu options (continued)

Change track option	Descriptions
M	Manage your site defined messages. See "SETUP - Change Track messages" on page 1670.
C	When you select this option a panel opens for browsing the messages defined by zSecure.

SETUP - Change Track Data Sets

By default, the Change Tracking system monitors changes to the protection of all data sets considered sensitive by REPORT SENSITIVE. In addition to these you can mark additional data sets as sensitive using SETUP - Change Track Data sets.

On entry to this option a list of sensitive data sets is displayed:

```
 Menu   Options   Info   Commands
------------------------------------------------------------------------------
                       zSecure Suite - Change Track Sens Row 1 to 2 of 2
Command ===> _____________________________________________ Scroll===> CSR

Insert, Delete or Select (I/D/S) a data set mask

     Data set mask                                  Access   System
                                                    level
     SYSAPP.**                                      UPDATE   CR#4
     SYS1.**                                        READ     *
****************************** Bottom of data ********************************
```

Figure 561. Setup Change Track - sensitive data sets

The first time you enter this option the list will be empty. You can add entries using the **I** line command:

```
 Menu   Options   Info   Commands
------------------------------------------------------------------------------
                       zSecure Suite - Change Track Sens Row 1 to 2 of 2
Command ===> _____________________________________________ Scroll===> CSR

Data set mask                                 Access   System
SYSAPP.DATA.**_____________________________ READ____ CR#4_________________
Reason Confidential application data sets_____________________________________
```

Figure 562. Setup Change Track - initial view of sensitive data sets panel

To mark a data set, or a group of data sets, as sensitive, the following fields must be defined:

Data set mask
An EGN mask matching the data sets that you consider sensitive.

Access
The level of access that you want to report on. For integrity-sensitive data sets, set the Access level to UPDATE. For confidentiality-ensitive data sets, set the access level to READ.

System
The SYSNAME of the system where these data sets are considered sensitive. If the data sets are sensitive on all your monitored systems, you can use an '*'.

Reason
This is a comment field to document why these data sets have been marked sensitive.

After specifying the desired settings, pressing ENTER to add the data sets to the list of sensitive data sets and return to the initial display.

```
  Menu   Options   Info   Commands
------------------------------------------------------------------------------
                        zSecure Suite - Change Track Sens Row 1 to 3 of 3
Command ===> _____________________________________________ Scroll===> CSR

Insert, Delete or Select (I/D/S) a data set mask

      Data set mask                                    Access   System
                                                       level
      SYSAPP.**                                        UPDATE   CR#4
      SYSAPP.DATA.**                                   READ     CR#4
      SYS1.**                                          READ     *
****************************** Bottom of data ********************************
```

Figure 563. Setup Change Track - list of sensitive data sets

The **D** action character can be used to remove a data set mask from the list. The **S** action command will display the sensitivity reason.

SETUP - Change Track messages

Use the Setup Change Track Messages option to maintain message IDs to be used with the Change Tracking system (AU.C). Each type of system change is associated with its own associated message ID. For example, message ID U000001 can be defined to represent the addition or deletion of a page data set. These messages use the following message prefix conventions to categorize messages by type.

- **U** indicates a site-defined message.
- **C** indicates a product message that cannot be changed.

```
  Menu   Options   Info   Commands
------------------------------------------------------------------------------
                        zSecure Suite - Site message table     Row 1 to 1 of 1
Command ===> _____________________________________________  Scroll===> CSR

Insert, Delete, Edit or Browse (I/D/E/B) a message id

   Message Number  Message Description
   U000001         MVS IPL page datasets
****************************** Bottom of data ********************************
```

Figure 564. Setup Change Track - Site message table

Table 658 describes the line commands for the Site message table.

Table 658. Setup Change Track - available line commands for the Site message table

Command	Description
I	Insert a new message id. This command allows you to monitor for changes that have not been predefined.
E	Edit the message id. This command can be used to change what is monitored or displayed by Change Tracking.
D	Delete a message id. After this command runs, the event that the message id describes is no longer tracked.

Table 658. Setup Change Track - available line commands for the Site message table (continued)

Command	Description
B	Browse the message id This can be used to see what is monitored or displayed by Change Tracking.

When you edit, browse or insert a Message id, the Message ID specification panel shown in Figure 565 opens for viewing, modifying, or specifying the message ID settings.

```
 Menu   Options   Info   Commands

Confirm allowed     YES  Reject allowed      YES

Enter NEWLIST type and CARLa define/select statements
NEWLIST type RACF
Define . . .
Select . . . CLASS=USER SEGMENT=BASE SPECIAL
****************************** Bottom of data ********************************
```

Figure 565. Setup Change Track - Site message detail view

The following fields are available to define or change a site message definition:

Message id
The ID (between U000001 and U999999) assigned to this type of change. The message ID must be unique.

Message description
Describes this type of change. The value is shown in the Change Tracking system.

Action on addition
Determines the appropriate action to take if the change is an addition and has not been approved.

Action on deletion
Determines the appropriate action to take if the change is a deletion and has not been approved.

Deletes reported
Determines if delete operations are reported for this attribute. Select YES or NO.

Additions reported
Determines if add operations are reported for this attribute. Select YES or NO.

Confirm allowed
Determines if users of the Change Tracking system are permitted to confirm this change. Select YES or NO.

Reject allowed
Determines if users of the Change Tracking system are permitted to reject this change. Select YES or NO.

newlist type
The NEWLIST type for reporting this change. You can specify any of the following types: AUTAB, CLASS, RACF, ROUTER, RRNG, SPT, TEMPLATE, CONSOLE, DASDVOL, DSNT, EXIT, IOAPP, JOBCLASS, MSG, PC, PPT, SENSDSN, SMFOPT, SUBSYS, SVC, or SYSTEM.

Define
Specify one CARLa define statement for both the selection and list operations. You only need to enter the define clauses, not the word *Define* itself.

Select
Specify one CARLa select statement to identify what you want to monitor. Selection fields must be valid for the NEWLIST type you specified earlier. You only need to enter the define clauses, not the word *Define* itself.

After you enter the message definition information, the panel shown in Figure 566 opens.

```
  Menu   Options   Info   Commands
------------------------------------------------------------------------------
                        zSecure Suite - Setup - Change  Row 1 to 31 of 31
Command ===> ____________________________________________________________

Enter fields, field lengths and descriptions to report
Fieldname               Length  Description
KEY                     8       Userid

****************************** Bottom of data ********************************
```

Figure 566. Setup Change Track - Site message reporting options

On this panel, you can specify the information in the message to include in the reports like the profile name or user name for example. Always specify the name values so that the details reported uniquely describe the change you are tracking. The following fields are available:

Field
Specifies the field name. You can use any of the valid field names for the NEWLIST type you specified as long as the field is not part of a repeat group.

Length
The output length of the field.

Description
Specifies the field description that is provided on the Change Tracking detail display.

The **SE.C.C** menu option for messages defined in zSecure shows a similar display panel. However, the only action command permitted is **B** (browse).

SE.N Setup - National Language Support

Although all Setup functions can be set individually, the Setup - National Language Support files option can apply system-wide or to a group of users, as a suboption under Setup default. See *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

SE.T Setup - Trace

Use Setup Trace for configuring the product to provide a trace. Most options are created for debugging and diagnostics. Consequently, they are turned off unless you are trying to diagnose a problem. Typically, you do not need to configure these options unless you are asked to do so by IBM software support. If you select the Trace command, these options can cause errors and unexpected results.

Figure 567 shows the Setup - Trace menu options panel that opens when you select the Setup Trace option from the Setup menu.

```
  Menu  Options  Info  Commands  Setup
--------------------------------------------------------------------------------
                     zSecure Suite - Setup -  Trace
Command ===> ____________________________________________________________

Diagnose syntax errors or enhance your CARLa knowledge
  /  List standard CARLa members

Use following options only at the direction of IBM sofware support
 Enter "/" to select option(s)
  _  Show parameters in run
  _  Show intermediate results during recursion
  _  Show ISPF dialog errors (if selected some parts may fail)
  _  Trace REXX programs
  _  Trace ISPF panel processing (z/OS 1.7 and up)
  _  Trace ISPF skeleton processing (z/OS 1.7 and up)
  _  Pass abends to ISPF
  _  Prevent closing/freeing data sets during abend recovery
  _  Suppress error traps (if selected some parts may fail)
  _  Debug action commands
  _  Show CKGRACF command flow
  _ Collect CKX diagnostic information
```

Figure 567. Setup Trace panel

Descriptions for the available Setup Trace options are provided in the following list.

List standard CARLa members
If this option is checked, all included members are shown expanded in the SYSPRINT file. The expanded view can be helpful for understanding the query sent to the product engine by the interface. This option is useful when you are developing or learning about CARLa programs.

Show parameters in run
If this option is checked, a panel opens to show the parameters passed to the program.

Show intermediate results during recursion
If this option is checked, commands generated during a recursive run are immediately displayed in BROWSE mode. Normally, the commands are presented after finishing the run.

Show ISPF dialog errors (if selected some parts may fail)
If this option is checked, the ISPF RETURN error mode is set (`CONTROL ERRORS RETURN`). Some parts of the interface might fail when this option is selected.

Trace REXX programs
If this option is selected, the panel shown in Figure 568 on page 1674 opens so you can set a specific REXX Trace option.

```
 Menu  Options  Info  Commands  Setup
_____________________________________________________________________________
                        zSecure Suite - Setup - Trace Rexx
Command ===> _____________________________________________________________

Select one of the following Rexx Trace options, or blank to disable tracing:
_  1. All            Traces all clauses before execution
   2. Commands       Traces all commands before execution
   3. Error          Traces any command resulting in an error or failure
   4. Intermediates  Traces all clauses and intermediate results
   5. Labels         Traces only labels passed during execution
   6. Normal         Traces any command resulting in a negative return code
   7. Results        Traces all clauses before execution and final results
```

Figure 568. Setup Trace REXX options

The selected Trace option is effective for all the zSecure REXX programs. For further information about the different Trace options, see the "TSO/E REXX reference".

Trace ISPF panel processing (z/OS 1.7 and up)
If this option is checked, a panel trace is activated using the ISPDPTRC command. After leaving the user interface, the output of the panel trace is displayed in VIEW mode.

This option is only available on z/OS 1.7 and up. Only use this option at the request of IBM software support in order to diagnose panel processing problems.

For further information about the ISPDPTRC command, see the IBM manual *ISPF Dialog Developer's Guide*.

Trace ISPF skeleton processing (z/OS 1.7 and up)
If this option is checked, a skeleton trace is activated using he ISPFTTRC command. After leaving the user interface, the output of the skeleton trace is displayed in VIEW mode.

This option is only available on z/OS 1.7 and up. Only use this option at the request of IBM software support in order to diagnose skeleton processing problems.

For further information about the ISPFTTRC command, see the IBM manual *ISPF Dialog Developer's Guide*

Pass abends to ISPF
If this option is checked, the NOCLEANUP parameter is added to the CARLa ALLOC command. This option can be used for debugging purposes to pass on abends to ISPF instead of recovering from them. Only use this option at the request of IBM software support when an attempt to cleanup the abend causes additional errors.

Prevent closing/freeing data sets during abend recovery
If this option is checked, the NOCLOSE parameter is added to the CARLa ALLOC command. This option can be used to prevent closing and freeing data sets during abend recovery processing. Only use this option at the request of IBM software support.

Suppress error traps (if selected some parts may fail)
Suppresses error traps during a debugging session. If this option is checked, the NOESTAE parameter is added to the CARLa ALLOC command. Setting this option can cause the product to stop working.

Debug action commands
Enables tracing of the authority checks made to decide which items are shown

on menus and which actions characters are available to the user. The trace is written to the C2RIMENU ddname and can be viewed using the C2RIMENU primary command. The option also enables tracing of action character processing by adding message CKR2829 in the SYSPRINT. The latter effect can also be achieved in user-defined queries by adding the CARLa command DEBUG ACTION.

Show CKGRACF command flow
If this option is checked, the CKGRACF DEBUG command is issued with some additional parameters before every CKGRACF command. The CKGRACF DEBUG command is designed to explore how CKGRACF operates or to diagnose problems in its operation. This option is especially helpful in determining why a certain CKGRACF command is not allowed.

Collect CKX diagnostic information
Enables collection of CKX diagnostic information. The information is written to the CKXDEBUG ddname and can be viewed using the CKXDEBUG primary command.

SE.W SETUP - Windows

Use the Setup Windows option for configuring zSecure Visual, the Microsoft Windows client for IBM Security zSecure Admin. This option is only available when zSecure Visual is installed and not disabled in IFAPRDxx. When you select SE.W, the panel shown in Figure 569 opens.

```
Menu         Options       Info    Commands     Setup
-------------------------------------------------------------------------------
                          zSecure Visual - Configuration
Command ===> ____________________________________________________   _ start panel

 1  1. Add, delete, or install zSecure Visual Windows client

Server  . . . . . . IPO1                                          (IP or DNS)
Server base port  . 8000                                 (IP base port of server)

Act Agent id         IP number or DNS name                         Port (opt.)
AP  12.1. 100_______ CRM100_____________________________________ __________

Act must be A, D, P, C, AP (A=add D=delete C=cancel pwd P=new pwd)
```

Figure 569. zSecure Visual - Configuration

For additional information about configuring the zSecure Visual client, see the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

SE.D SETUP - Default

Use the Setup Default option for configuring installation-wide default settings. For more information, see the *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

SE.R Setup - Reset to system default

Use the Setup Reset option to reset your settings to the system default values. The default settings are copied over your settings. Your personal sets of input files remain unchanged, only the system-defined sets are replaced by the new sets.

SE.I Setup - Installation

Although all Setup functions can be set individually, the Setup Installation option can be used to set system-wide options or options for user groups. It is a suboption of the Setup Default option. For more information, see *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*.

CO Commands - Run Commands from Library

The LIBRARY application is always available as option **CO** from the main menu. It lets you manage your own libraries of commands, or run CARLa queries supplied with the product. The panel is organized from top to bottom to use: data sets (**1**), member list (**2**), specific members (**3**-**5**), and commands stored in ISPF profile (**C**).

```
 Menu  Options  Info  Commands  Setup          StartPanel
--------------------------------------------------------------------------------
                      zSecure Suite - Commands
Option ===> ____________________________________________________________

 1      Libraries       Select and maintain command library
 2      Members         Work with members from current command library
 3      Edit            Edit member from current command library
 4      Run             Run member from current command library
 5      Submit          Run member from current command library in background
 C      Command         Type in any CARLa command

 Member name . . . . ________      (If 3, 4 or 5 selected)
 Two pass query  . . N             (Y/N, option 4 only)
 Current library . . DD:CKRCARLA
 Input complex . . . Control blocks in common storage and live SMF datasets
 Current mask type . EGN
```

Figure 570. Commands menu

The next pages describe the options **1**, **2** and **C**. Options **3** to **5** operate directly on the member entered on the panel. Option **Two pass** query is only applicable for option **4**. Select `Y` when it is a two-pass query and no customization is necessary.

CO.1 LIBRARIES - Data set selection

Option **CO.1** allows you to allocate and select an existing library for subsequent use. The initial contents of this option is the system default set as described in *IBM Security zSecure CARLa-Driven Components: Installation and Deployment Guide*. If no default is specified, this setting contains only DD:CKRCARLA, the ddname for the default CARLa library. You can use the I line command to insert new libraries. To activate a library use the `S` line command.

```
 Menu   Options   Info   Commands
--------------------------------------------------------------------------------
                       zSecure Suite - Setup - Command file Row 1 from 3
Command ===> ____________________________________________ Scroll ===> CSR

Select CARLa script library or work with a library (E, R, I, or D)

   CARLa script library
_  DD:CKRCARLA                                                      default
****************************** Bottom of data ********************************
```

Figure 571. Setup - Command file panel

Each line in the library selection list must contain a data set name using TSO conventions, or DD: followed by an allocated filename. The library marked **selected** is used by the other options of the COMMANDS menu.

The following line commands can be used to select libraries.

E	Show the members in this library
D	Delete the line from the selection list, the data set is **not** deleted
I	Insert an empty line following this line, it is not selected automatically
R	Repeat name in this line
S	Select the library for subsequent use

When you have selected a data set, you can call up a member list of the data set with the E line command, or exit the library selection panel and use option **CO.2**.

CO.2 MEMBERS - Member selection

You can use the member selection panel to select a member for edit or to invoke the program in the foreground or in the background with the selected member as input.

```
LIBRARY          C##A.D.C##NEW.SCKRCARL                  Row 00001 of 00008
Command ===> _____________________________________________ Scroll ===> CSR
Valid line commands are B(browse), E(edit), J(job) and R(run in foreground)
   Name     Prompt          Size    Created          Changed          ID
. CKRL$ALL                   27   1998/03/10   1998/03/10 14:16:11   RCR2300
. C2RL$UNL                   25   1997/05/16   2000/06/19 18:04:06   RCR2600
. CKRLAC1                    66   1998/02/12   2001/09/17 17:19:03   C##ASCH
. CKRLAPPL                   24   1998/02/12   1998/02/12 15:19:27   RCR2300
. CKRLAUD                    36   1997/02/24   1997/02/24 12:15:45   RCR2200
. CKRLAUTH                   66   1998/02/12   2001/09/17 17:27:10   C##ASCH
. CKRLCICS                  133   1998/02/12   1998/02/12 15:19:52   RCR2300
. CKRLCICT                   32   1998/02/12   1998/02/12 15:19:01   RCR2300
```

Figure 572. Command Library - Member selection panel

The member selection list supports the following primary commands:

```
EDIT member
SELECT member
LOCATE member
SORT column
```

You can abbreviate the Edit and Select keywords as `E` and `S`, respectively. The `Member` can be a new or an existing member name, or a pattern with an asterisk. For example, to limit the list to members that start with *`CKRL`*, you can enter *`S CKRL*`*.

Table 659 lists the commands for selecting members.

Table 659. Command Library Member selection line commands

B	Browse a member
E	Edit a member
J	Submit a job with the member as input
R	Run the program in the foreground using the member as input
S	An alias for E

For information about the commands for editing a member, see “Primary commands” on page 11.

CO.C COMMAND - Type in any CARLa Command

Use Option **CO.C** to run CARLa (CARLa Auditing and Reporting Language) commands and view the output. (See Chapter 12, “CARLa Command Language,” on page 713 for CARLa command documentation.) The commands you enter are saved in the ISPF profile data set for later reference. After the commands complete, you are presented with the report file if present, or with the message file if no report is produced.

- Run a CARLa command and view the output.
- Save the command input for later use.

Commands can be entered using the ISPF editor. The editor opens the current library, SCKRCARL, for example and uses a member name that consists of a number sign (#) followed by your userid. If such a member exists in the library, the content is not used, nor is it destroyed when you leave the editor. Enter SAVE to save the commands in the ISPF profile, enter CANCEL to leave the editor without saving the contents. Figure 573 shows the panel for entering the commands.

```
  Menu  Options  Info  Commands  Setup
------------------------------------------------------------------------------
EDIT ---- C##.C2R113.SCKRCARL(#USERID)  - 01.00              Columns 00001 00080

''''''
****** **************************** Bottom of Data ****************************
```

Figure 573. Command input panel

When you enter GO or RUN on the command line, the commands in the editor are executed by Security zSecure, at your terminal. When you enter SUB or SUBMIT, a batch job is generated to run the commands, with the same options and input files that your current ISPF session uses.

The primary command CARLa directly invokes this option.

An introduction to CARLa

The following sections give some examples of the use of the LIST and SORTLIST commands, optionally together with SELECT parameters. The LIST and SORTLIST commands can be used to In addition, multiple custom reports can be generated using the NEWLIST command.

Use LIST and SORTLIST commands to create customized reports for RACF profile information.

Use the NEWLIST command to generate multiple custom reports.

Use SELECT and EXCLUDE commands to select the records and information to be included in the report.

If no SELECT/EXCLUDE is given, all profiles are selected by default. The advantage of NEWLIST is that each custom report can have its own selection statements.

Listing profile fields

Use the following CARLa commands to select and list the profile fields to include in a custom report or ISPF display.

- LIST
- SORTLIST
- DISPLAY
- SUMMARY

The parameters of these commands are field names. Field names can include the following value types:

- Values defined by Security zSecure such as CLASS and KEY
- Built-in alias names defined for commonly used flags like SPECIAL.
- Field names defined in the RACF database *templates*.

The templates can be displayed using the `SHOW TEMPLATE` command, or by running the TEMPLATE command from the Security zSecure command line. Sample templates are listed in "TEMPLATE - Template field properties" on page 284. A reference of the field names available is included in "RACF: RACF profiles" on page 1124.

As an example, the code to list profile class, name, and standard access list:

```
SORTLIST CLASS KEY USERID USERACS
```

This query might for example give the following output (REPORT file and SYSPRINT file, only relevant parts are displayed).

```
Include CKRALLOC (ISPF variable)
     2 |alloc type=CKFREEZE dsn='SYSAPPL.CNRACF.CKFREEZE'  complex=DINO rrsfnode=THESRRSF
     3 |
     5 |alloc type=UNLOAD dsn='SYSAPPL.CNRACF.UNLOAD'  complex=DINO rrsfnode=THESRRSF
     6 |
     8 |/* Daily Backup */

Figure 574. Sample SORTLIST output with access list - SYSPRINT and REPORT files

Generally, issuing the SORTLIST or LIST command generates more output than you want. The results of these commands include at least one line for each segment for each profile in the database if the database is in Restructured Data Set format. You can use the SELECT command to define selection criteria to limit the profiles included in the results. For instance:

```
SELECT CLASS=DATASET SEGMENT=BASE
SORTLIST CLASS KEY USERID USERACS
```

Sample output for this function:

```
P R O F I L E   L I S T I N G   12 Oct 2001 00:07                                                    Page 1

DATASET  ADM1.SPECIAL.*
DATASET  ADM1.SPECIAL.*.**
DATASET  ADM1.SPECIAL.**
```

Figure 575. Sample SORTLIST output with access list - DATASET profiles

The width of each column is derived from the templates and from an internal table. You can modify this width by giving the length in parentheses. For example, since you know that for the GLOBAL class, the profile name is a RACF class, and class names are not longer than 8 characters, you can issue the following CARLa commands:

```
SELECT CLASS=GLOBAL
SORTLIST CLASS KEY(8) MEMLST
```

These statements print all GLOBAL profiles with their member profiles as shown in Figure 576 on page 1681. zSecure automatically formats the option bytes in the

members. For GLOBAL profiles, it is the universal access.

```
P R O F I L E   L I S T I N G   12 Oct 2001 00:07                                                    page    1

```

Figure 576. Sample SORTLIST output with explicit length

The major LIST, SORTLIST, and DISPLAY commands each behave differently in terms of the sequence of the profile listing and in the use of main memory.

- The LIST command outputs the profiles in the order as present in the RACF database or unloaded input file.

  The SORTLIST and DISPLAY commands sort the profiles in ascending order according to the sequence of field names on the command.
- The LIST command does not store the profiles in main memory.

  The SORTLIST and DISPLAY commands store and sort the profiles in main memory.

The LIST command is therefore more suited to tasks requiring further postprocessing by computer, while SORTLIST and DISPLAY are ideal for making reports and displays based on the selected field names.

The following command shows an example of the standard CKRLPROG member supplied in the SCKRCARL data set, combining the commands discussed before.

```

```

Figure 578. Sample output from the CARLa script CKRLPROG (first page only) - Part 2

In the SYSPRINT file shown in the preceding figure, we see that the query specified in the interface (ISPF variable CKRCMDV) was in this case

```
I DD=CKR2CRL M=CKRLPROG
```

which resulted in the inclusion of the CARLa script CKRLPROG from the CKRCARLA ddname (as listed for DDname CKR2CRL—apparently this was a run from ISPF logical screen 2). The CKRLPROG script contains some comments (between "/*" and "*/" pairs) and two separate queries, each starting with a NEWLIST command; the NEWLIST command serves to separate queries as well as to define certain attributes for the report generated by the (following) query, in this case the TITLE to be printed above each page. The first query consists of a SELECT command and a SORTLIST command. The SORTLIST command includes a nondisplay column KEY up front (this column does not result in any output, but it does determine the primary sort order); because of the '|' modifier, the column separator normally printed before a second column is suppressed. The member list (MEMLST) is internally sorted before being printed because of the SORT repeated field modifier. The Universal ACCess level is also printed, truncated to three characters, as is the ACcess List (which results in several columns), and finally ACL:PGMRNAME is a lookup(:) of the user name (PGMRNAME), being done based on the ids on the Access list (to print the user name next to the userid). Only the first page of output of the first query is shown; the output of the second query is not visible.

Finding specific profile field contents

To search for profiles with a specific value in some profile variable field (not a flag field), you can use the general field-value selection mechanism.

Note: Flag fields all have distinct SELECT keywords for the flags. See "Finding profiles with specific attributes" on page 1684).

Generally, a field-value selection can be made with the following command:

```
SELECT fieldname=fieldvalue
```

Note: Flag fields all have distinct SELECT keywords for the flags - see "Finding profiles with specific attributes" on page 1684).

In this statement, the *fieldname* must be the name of the profile field as present in the templates in the RACF database. For a listing of these names, see the IBM RACF manual *Macros and Interfaces*. You can use the command in a batch program or type TEMPLATE on any ISPF panel to obtain a listing of the field names that are defined in your database. "TEMPLATE - Template field properties" on page 284 contains sample output of this command.

The value *fieldname* must be in a format consistent with the type of the field. For example, an access level can have values such as *READ* and *UPDATE*. If the value contains a generic character `%` or `*`, the value is used as a filter where `%` matches one character and `*` matches a qualifier (all characters up to `.` (a period). If the value starts with `:` (a colon), the field is scanned for a substring.

Table 660 list the values supported by the operator field.

Table 660. Profile field - supported operators

Operator	Description
=	Equal
<	Less than
>	Greater than
<=	Less than or equal
>=	Greater than or equal
<>	Not equal
¬=	Not equal

For values that indicate a filter, only equality and inequality operators are supported.

For example, to select data sets with a universal access greater than or equal to UPDATE, you might give the following commands:

```
SELECT CLASS=DATASET, UACC>=UPDATE
SORTLIST CLASS, KEY, UACC
```

Figure 579 on page 1684 gives an example of the output.

```
P R O F I L E   L I S T I N G   28 Oct 1997 00:05                                page 1

```

Figure 579. Sample SELECT with field value selection

You can also search for date fields in profiles. To find all TSO users who have never logged on, or users who have not changed their password, use the following code:

```
SELECT CLASS=USER, S=BASE
NEWLIST TITLE='never logged on'
  SELECT LJTIME='FFFFFFFF'X
  SORTLIST KEY(8) PGMRNAME DFLTGRP OWNER DEFDATE
NEWLIST TITLE='password unchanged for 90 days'
  SELECT PASSDATE<DUMPDATE-90
  SORTLIST KEY(8) PGMRNAME DFLTGRP OWNER DEFDATE PASSDATE
```

You can review the full program for this query in the CARLa scripts CKRLLGNU for the List Logon Never Used report and CKRDLGNU for the List Logon Never Used display output.

The following CARLa statements show an example of scanning for owner fields starting with *SYS*:

```
SELECT CLASS=DATASET OWNER=SYS*
SORTLIST CLASS KEY OWNER
```

The following CARLa statements show an example of scanning for user names containing a substring JONES or SMITH:

```
SELECT CLASS=USER NAME=:(JONES,SMITH)
SORTLIST CLASS KEY(8) NAME
```

Finding profiles with specific attributes

The RACF database can be scanned for users with specific attributes using keywords on the SELECT command. This scanning cannot easily be done easily using the field-value selection described in “Finding specific profile field contents” on page 1683 because the attributes are flags in flag bytes. The SELECT command aims to provide two keyword parameters for each attribute (flag): one for selection if the flag is on, and one for selection if the flag is off. For example, to find users with the UAUDIT (user-audit) attribute, use the following CARLa commands:

```
SELECT CLASS=USER UAUDIT
LIST CLASS KEY
```

To find users *without* the UAUDIT attribute, use the following CARLa commands:

```
SELECT CLASS=USER NOUAUDIT
LIST CLASS KEY
```

To find users with group-SPECIAL attribute, use the following CARLa command:

```
SELECT CLASS=USER GRPSPECIAL
```

To select system-wide and group-special users:

```
SELECT SPECIAL OR GRPSPECIAL
```

For a complete overview of the numerous attributes supported as well as additional examples, see the reference material in “SELECT and EXCLUDE” on page 884.

The following example in Figure 580 shows part of the result of the standard input member CKRLPROG provided in the SCKRCARL library. It selects PADS data sets using the PADS keyword on the SELECT command combined with restriction to the DATASET class. The SORTLIST command requests a listing of the data set type, volume serial, data set name, universal access, standard access list, and conditional access list for the selected profiles. The sort order is defined by the order of the field names. In this example, the fields are data set name (`dsn`), volume serial (`volser`), and data set type (`dstype`).

Finding all occurrences of a string

You can use the following CARLa commands to run a quick scan of the entire RACF database for a specified string:

```
SELECT SCAN=string
SORTLIST CLASS, KEY
```

These commands produce output like the output shown in Figure 582 on page 1687.

```
P R O F I L E   L I S T I N G   28 Oct 1997 00:05                    page 1

Figure 582. Sample SORTLIST output with SELECT SCAN=

The SCAN parameter scans all of the fields in each profile. To limit the scan to a particular field, the FIELD parameter can be specified on the SELECT command as shown in the following example:

```
SELECT CLASS=DATASET FIELD=INSTDATA SCAN=string
SORTLIST CLASS KEY INSTDATA
```

These commands search for *string* in the installation data of DATASET profiles. This search can also be performed using the following commands:

```
SELECT CLASS=DATASET INSTDATA=:string
SORTLIST CLASS KEY INSTDATA
```

USRDATA - Reporting on user fields

The USR field is a rather special case in zSecure, somewhat like the ACL field. The USR field is a combination field containing the *user fields*USRNM, USRFLG, and USRDATA. These fields cannot be set or listed using normal RACF commands, but they are used by IBM and third-party developers to store information in RACF profiles. The CKGRACF authorized component of zSecure provides access to the user fields in most profile types and also uses these fields to store CKGRACF-specific settings. The USR field, its use in zSecure, and the CKGRACF-specifics, are described in detail "User fields." For more information of the CKGRACF authorized component, see "Auditing CKGRACF" on page 371.

User fields

The following example shows how to display information stored in user fields in the USER class by using the following commands:

```
select class=user usrcnt>0
sortlist class key(8) usrcnt usrnm usrflg usrdata usr("Combination field")
```

The following report contains information that includes phone/fax numbers, email addresses, and CKGRACF data. Both the USRNM, USRFLG and USRDATA fields and the USR combination field are listed. The USR field has special support to interpret CKGRACF data.

Appendix A. Reading Syntax Diagrams

The following rules apply to the syntax diagrams used in this manual:

- Read the syntax diagrams from left to right, from top to bottom, following the path of the line.
  - The ▸▸— symbol indicates the beginning of a statement.
  - The —▸ symbol indicates that the statement syntax is continued on the next line.
  - The ▸— symbol indicates that a statement is continued from the previous line.
  - The —▸◂ symbol indicates the end of a statement.
  - Diagrams of syntactical units other than complete statements start with the ▸— symbol and end with the —▸ symbol.
- Required items appear on the horizontal line (the main path).

- Optional items appear below the main path.

- If an optional item appears above the main path, that item has no effect on the execution of the statement and is used only for readability.

- If you can choose from two or more items, they appear vertically, in a stack.
  - If you must choose one of the items, one item of the stack appears on the main path.

  - If choosing one of the items is optional, the entire stack appears below the main path.

  - If one of the items is the default, it appears above the main path and the remaining choices are shown below.

- An arrow returning to the left, above the main line, indicates an item that can be repeated.
  - If the repeat arrow does not include any characters, you must separate repeated items with a space.

  - If the repeat arrow contains a comma, you must separate repeated items with a comma.

  - A repeat arrow above a stack indicates that you can repeat the items in the stack.
- Keywords appear in uppercase (for example, **USER**). They must be spelled exactly as shown. Variables appear in all lowercase letters (for example, *userid*). They represent user-supplied names or values.
- If punctuation marks, parentheses, arithmetic operators, or other such symbols are shown, you must enter them as part of the syntax.

Appendix B. Support information

This section describes the following options for obtaining support for IBM products:

Searching knowledge bases

You can often find solutions to problems by searching IBM knowledge bases. Learn how to optimize your results by using available resources, support tools, and search methods and how to receive automatic updates.

Available technical resources

In addition to the Security zSecure information center, you can access the following technical resources to help you answer questions and resolve problems:

- Access the Tivoli support site to view technotes, APARs (problem reports) and other related information at http://www-01.ibm.com/software/sysmgmt/products/support/IBMTivolizSecureSuite.html
- Access the Redbooks Domain to locate current redbooks for Security zSecure at http://www.redbooks.ibm.com/
- Access Tivoli support forums and communities at http://www-01.ibm.com/software/sysmgmt/products/support/Tivoli_Communities.html

Searching with support tools

The following tools are available to help you search IBM knowledge bases:

- **IBM Support Assistant** (ISA) is a free software serviceability workbench that helps you resolve questions and problems with IBM software products. Instructions for downloading and installing the ISA can be found on the ISA website: http://www.ibm.com/software/support/isa.
- **IBM Software Support Toolbar** is a browser plug-in that provides you with a mechanism to easily search IBM support sites. You can download the toolbar at http://www.ibm.com/software/support/toolbar/.

Searching tips

The following resources describe how to optimize your search results:

- Searching the IBM Support website: http://www-01.ibm.com/support/us/srchtips.html
- Using the Google search engine:http://www.google.com/support/

Obtaining fixes

A product fix might be available to resolve your problem. To determine which fixes are available for your Tivoli software product, follow these steps:

1. Go to the IBM Software Support website at http://www.ibm.com/software/support.
2. Under **Select a brand and/or product**, select **Tivoli**.
3. Click the right arrow to view the Tivoli support page.
4. Use the **Select a category** field to select the product.
5. Select your product and click the right arrow that shows the **Go** hover text.
6. Under **Download**, click the name of a fix to read its description and, optionally, to download it.

   If there is no **Download** heading for your product, supply a search term, error code, or APAR number in the field provided under **Search Support (this product)**, and click the right arrow that shows the **Go** hover text.

For more information about the types of fixes that are available, see the *IBM Software Support Handbook* at http://techsupport.services.ibm.com/guides/handbook.html.

Receiving weekly support updates

To receive weekly e-mail notifications about fixes and other software support news, follow these steps:

1. Go to the IBM Software Support website at http://www.ibm.com/software/support.
2. Click **My support** in the far upper right corner of the page under **Personalized support**.
3. If you have already registered for **My support**, sign in and skip to the next step. If you have not registered, click **register now**. Complete the registration form using your e-mail address as your IBM ID and click **Submit**.
4. The **Edit profile** tab is displayed.
5. In the first list under **Products**, select **Software**. In the second list, select a product category (for example, **Systems and Asset Management**). In the third list, select a product sub-category (for example, **Application Performance & Availability** or **Systems Performance**). A list of applicable products is displayed.
6. Select the products for which you want to receive updates.
7. Click **Add products**.
8. After selecting all products that are of interest to you, click **Subscribe to email** on the **Edit profile** tab.
9. In the **Documents** list, select **Software**.
10. Select **Please send these documents by weekly email**.
11. Update your e-mail address as needed.
12. Select the types of documents you want to receive.
13. Click **Update**.

If you experience problems with the **My support** feature, you can obtain help in one of the following ways:

Online
Send an e-mail message to erchelp@ca.ibm.com, describing your problem.

By phone
Call 1-800-IBM-4You (1-800-426-4968).

Registering with IBM Software Support

Before you can receive weekly e-mail updates about fixes and other news about IBM products, you need to register with IBM Software Support. To register with IBM Software Support, follow these steps:

1. Go to the IBM Software Support site at the following Web address:

   http://www.ibm.com/software/support
2. Click **Register** in the upper right corner of the support page to establish your user ID and password.
3. Complete the form, and click **Submit**.

Contacting IBM Software Support

IBM Software Support provides assistance with product defects.

Before contacting IBM Software Support, your company must have an active IBM software maintenance contract, and you must be authorized to submit problems to IBM. The type of software maintenance contract that you need depends on the type of product you have:

- For IBM distributed software products (including, but not limited to, Tivoli, Lotus, and Rational® products, and DB2 and WebSphere® products that run on Windows or UNIX operating systems), enroll in Passport Advantage® in one of the following ways:

  Online
  Go to the Passport Advantage website at http://www-306.ibm.com/software/howtobuy/passportadvantage/pao_customers.htm .

  By phone
  For the phone number to call in your country, go to the IBM Software Support website at http://www14.software.ibm.com/webapp/set2/sas/f/handbook/contacts.html and click the name of your geographic region.
- For customers with Subscription and Support (S & S) contracts, go to the Software Service Request website at https://techsupport.services.ibm.com/ssr/login.
- For customers with IBMLink, CATIA, Linux, OS/390, iSeries®, pSeries®, zSeries, and other support agreements, go to the IBM Support Line website at http://www.ibm.com/services/us/index.wss/so/its/a1000030/dt006.
- For IBM eServer™ software products (including, but not limited to, DB2 and WebSphere products that run in zSeries, pSeries, and iSeries environments), you can purchase a software maintenance agreement by working directly with an IBM sales representative or an IBM Business Partner. For more information about support for eServer software products, go to the IBM Technical Support Advantage website at http://www.ibm.com/servers/eserver/techsupport.html.

If you are not sure what type of software maintenance contract you need, call 1-800-IBMSERV (1-800-426-7378) in the United States. From other countries, go to the contacts page of the *IBM Software Support Handbook* on the Web at

http://www14.software.ibm.com/webapp/set2/sas/f/handbook/contacts.html and click the name of your geographic region for phone numbers of people who provide support for your location.

To contact IBM Software support, follow these steps:

1. "Determining the business impact"
2. "Describing problems and gathering information"
3. "Submitting problems"

Determining the business impact

When you report a problem to IBM, you are asked to supply a severity level. Use the following criteria to understand and assess the business impact of the problem that you are reporting:

Severity 1
The problem has a *critical* business impact. You are unable to use the program, resulting in a critical impact on operations. This condition requires an immediate solution.

Severity 2
The problem has a *significant* business impact. The program is usable, but it is severely limited.

Severity 3
The problem has *some* business impact. The program is usable, but less significant features (not critical to operations) are unavailable.

Severity 4
The problem has *minimal* business impact. The problem causes little impact on operations, or a reasonable circumvention to the problem was implemented.

Describing problems and gathering information

When describing a problem to IBM, be as specific as possible. Include all relevant background information so that IBM Software Support specialists can help you solve the problem efficiently. To save time, know the answers to these questions:

- Which software versions were you running when the problem occurred?
- Do you have logs, traces, and messages that are related to the problem symptoms? IBM Software Support is likely to ask for this information.
- Can you re-create the problem? If so, what steps were performed to re-create the problem?
- Did you make any changes to the system? For example, did you make changes to the hardware, operating system, networking software, and so on.
- Are you currently using a workaround for the problem? If so, be prepared to explain the workaround when you report the problem.

Submitting problems

You can submit your problem to IBM Software Support in one of two ways:

Online
Click **Submit and track problems** on the IBM Software Support site at http://www.ibm.com/software/support/probsub.html. Type your information into the appropriate problem submission form.

By phone
For the phone number to call in your country, go to the contacts page of the

IBM Software Support Handbook at http://www14.software.ibm.com/webapp/set2/sas/f/handbook/contacts.html and click the name of your geographic region.

If the problem you submit is for a software defect or for missing or inaccurate documentation, IBM Software Support creates an Authorized Program Analysis Report (APAR). The APAR describes the problem in detail. Whenever possible, IBM Software Support provides a workaround that you can implement until the APAR is resolved and a fix is delivered. IBM publishes resolved APARs on the Software Support website daily, so that other users who experience the same problem can benefit from the same resolution.

Appendix C. Notices

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not give you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing
IBM Corporation
North Castle Drive
Armonk, NY 10504-1785
U.S.A.

For license inquiries regarding double-byte (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

Intellectual Property Licensing
Legal and Intellectual Property Law
IBM Japan, Ltd.
1623-14, Shimotsuruma, Yamato-shi
Kanagawa 242-8502 Japan

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law:

INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE.

Some states do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement might not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM Web sites are provided for convenience only and do not in any manner serve as an endorsement of those Web

sites. The materials at those Web sites are not part of the materials for this IBM product and use of those Web sites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

IBM Corporation
2Z4A/101
11400 Burnet Road
Austin, TX 78758 U.S.A.

Such information may be available, subject to appropriate terms and conditions, including in some cases payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurement may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not

been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. You may copy, modify, and distribute these sample programs in any form without payment to IBM for the purposes of developing, using, marketing, or distributing application programs conforming to IBM's application programming interfaces.

If you are viewing this information in softcopy form, the photographs and color illustrations might not be displayed.

Trademarks

IBM, the IBM logo, and ibm.com are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the Web at "Copyright and trademark information" at www.ibm.com/legal/copytrade.shtml.

Adobe, the Adobe logo, Acrobat, PostScript, and the PostScript logo are either registered trademarks or trademarks of Adobe Systems Incorporated in the United States, and/or other countries.

IT Infrastructure Library is a registered trademark of the Central Computer and Telecommunications Agency which is now part of the Office of Government Commerce.

Intel, Intel logo, Intel Inside, Intel Inside logo, Intel Centrino, Intel Centrino logo, Celeron, Intel Xeon, Intel SpeedStep, Itanium, and Pentium are trademarks or registered trademarks of Intel Corporation or its subsidiaries in the United States and other countries.

Linux is a registered trademark of Linus Torvalds in the United States, other countries, or both.

Microsoft, Windows, Windows NT, and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.

ITIL is a registered trademark, and a registered community trademark of the Office of Government Commerce, and is registered in the U.S. Patent and Trademark Office.

UNIX is a registered trademark of The Open Group in the United States and other countries.

Cell Broadband Engine is a trademark of Sony Computer Entertainment, Inc. in the United States, other countries, or both and is used under license therefrom.

Linear Tape-Open, LTO, the LTO Logo, Ultrium and the Ultrium Logo are trademarks of HP, IBM Corp. and Quantum in the U.S. and other countries.

Other company, product, and service names may be trademarks or service marks of others.
